THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

INTESTINES are that portion of the digestive canal into which the food is received after it has been partially digested in the stomach, and in which its further assimilation, the separation and absorption of the nutritive matter, and the removal of that which is excrementitious, take place. In an adult, the intestines consist of a convoluted tube of from 30 to 40 feet in length, and are, from the difference of their diameters in different parts, divided into small intestines, which comprise about the first four-fifths, and large intestines, which constitute the other fifth of their length. The former again are divided into the duodenum, into which the ducts from the liver and pancreas open, and in which the chyme from the stomach is converted into chyle [DIGESTION; CHYLE]; the jejunum, in which the absorption of the nutritive matter of the food is principally effected; and the ileum. The large intestines are divided into the cœcum, colon, and rectum.

The walls of the intestinal canal are composed of three principal coats or membranes. The exterior, which is smooth and polished, is called the peritoneal, and its principal use is to permit the free motions of the intestines within the abdomen, and of their several convolutions against each other, by rendering the effect of friction as slight as possible. Next to and within the peritoneal coat is the muscular, which is composed of two layers of fibres; an external, in which they are directed longitudinally, and an internal, of which the fibres encircle the intestine. By these the motions of the intestines and the propulsion of their contents are effected; the longitudinal fibres tending to shorten each portion of the canal, while the circular contract its diameter; and the two sets together producing a motion of the tube somewhat like that of a worm, whence it has received the name of vermicular motion. Beneath these layers, and separated from them by a stratum of cellular tissue, which has been sometimes called the fourth or nervous coat, is the mucous membrane, which is the most important part of the intestinal canal. It is everywhere beset by innumerable minute glands, by which the secretion of mucus and the other intestinal juices is carried on. In the small intestines it has a fine velvet-like surface, made up of minute thickly-set hair-like processes, or villi, which are about $\frac{1}{50}$th of an inch in length, and stand up so that their tops seem to form a smooth surface like the pile of velvet. These, as well as all the rest of the mucous membrane, are protected from the irritation which the immediate contact of foreign substances would produce, by a covering of an inorganic cuticle of extreme delicacy, called epithelium.

The principal functions performed by the intestines are the conversion of the chyme [DIGESTION; GASTRIC JUICE] into chyle, the absorption of the latter, and the removal of the innutritious parts of the food and of a considerable quantity of excrementitious matter. In the first process, which constitutes the last stage of digestion, the secretions of the liver and pancreas take an important part: the ducts by which they are conveyed open into the intestinal canal, near the middle of the duodenum, or about six inches from the aperture by which the food passes from the stomach; and immediately beyond the orifices of these ducts the villi are of great size, and thickly set on prominent folds of the mucous membrane, called valvulæ conniventes. These folds, at the same time that they increase the extent of surface for absorption, serve to entangle the semifluid mass of food, now completely digested; they are most numerous and prominent in the jejunum, where absorption is carried on earliest and most rapidly, but are found to a slighter extent throughout the whole of the small intestines.

The absorption of the chyle is effected by the villi, each of which is composed of a minute tube, which is the termination of a branch of the lacteal or absorbent system of vessels, and is ensheathed in a delicate tissue containing a net-work of capillary arteries and veins. The form and function of the villi may be best demonstrated in an animal which has died suddenly after a full meal; they then appear turgid, and stand erect, filled with a whitish milky fluid, the chyle, which, as fast as it is absorbed by them, is conveyed by numerous converging streams into the main trunk of the absorbent system, called the thoracic duct, through which it is gradually poured into the blood of the left subclavian vein, at a short distance before it enters the right side of the heart. [HEART.] The whole process of absorption is not unaptly compared to that by which the fluids are conveyed from the earth through the roots into the stem of a plant; the villi of the intestine being represented by the tufts of hair-like spongioles which are placed at the terminations of the fibres of the root.

The portion of the food which is unfit for the nourishment of the body is forced onwards by the vermicular motion of the intestines, and being mixed with the resinous and other excrementitious substances secreted by the liver and other glands, is conveyed through the whole tract of the intestines; and after it has been exposed to the absorbing vessels, which are placed in greater or less abundance in every part of the canal, so that not a particle of nutriment can be lost, the residue is voided.

INTONATION, in vocal music, is the tuning of the voice—the singing true or false—in tune or out of tune. Correct *Intonation* is the first requisite in a singer: this wanting, all his other musical qualities, however good, are unavailing.

INTRA'DOS and **EXTRA'DOS**, the lower and higher curves of an arch. [ARCH.]

INTRICA'RIA, a small Polypifer from the oolitic rocks of France, allied to Cellaria. (M. Defrance, *Dic. des Sci. Nat.*)

INTUITION (*intueri*), the most simple act of the reason or intellect, on which, according to Locke, 'depends all the certainty and evidence of all our knowledge; which certainty every one finds to be so great, that he cannot

same, and therefore cannot require a greater. For a man cannot conceive of a greater certainty than that any idea in his mind is such as he perceives it to be, and that two ideas, wherein he perceives a difference, are different and not precisely the same.' His definition, or rather explanation, of intuition is as follows:—'Sometimes the mind perceives the agreement or disagreement of two ideas immediately by themselves, and this, I think, we may call intuitive knowledge. In this the mind is at no pains of proving or examining, but perceives the truth as the eye does the light, only by being directed to it.' (*Essay on Human Understanding*, b. iv., c. ii., § 1.) Campbell's definition is similar: having defined truth to be the conformity of our conceptions to their antetypes in the nature of things, he declares intuitive truth to be that 'which is perceived immediately on a bare attention to the ideas under review.'

The nature of the relation which subsists between intuition and reasoning has been strongly contested. While Beattie maintains that the connexion between them, how closely soever they are found in general to be connected, is not necessary, but, on the contrary, a being endued with one may be destitute of the other; Dugald Stewart, on the other hand, insists that the two are not radically distinct, although by most writers they are considered to be different faculties. Locke having rightly maintained that every step which the reason makes in demonstrative knowledge has intuitive certainty, and that consequently the power of reasoning presupposes that of intuition, Stewart thinks that the intuition of Locke implies the power of reasoning; or, at least, that intuition combined with memory explains reasoning. Here his usual sagacity appears to have failed Stewart. While the mind itself is perfectly simple, it has been, for the purpose of attaining accuracy of language and distinctness of theory, supposed to be multiple; and distinct faculties have been ascribed to it according as its several operations comprise more or fewer elements. According therefore to his own account, reason, which involves the element of time, must be kept distinct from intuition, which does not involve that element.

The proper objects of intuitive certainty are identical propositions. This of course does not mean propositions verbally identical: such as 'a man is a man.' But while the object of thought is perfectly and always one, it may present itself to the thought under a variety of aspects, either dissolved into its elements or as combined into a whole. It is this identity under an apparent diversity that constitutes that original and primary evidence which makes certain propositions, as soon as the respective terms are understood, to be perceived intuitively. On the other hand, the apparent identity of a real diversity is the ground of all sophistical argument. The ultimate form of legitimate argumentation is, $a = b$, $b = c$, $\therefore a = c$. But every fallacy, when detected, will invariably be found to be $a = b \pm r$, $b = c$, $\therefore a = c$. The sophistry consists in the suppression of the element r, either positive or negative.

In the philosophy of Kant the term intuition (anschauung) is used to denote the single act of the sense upon outward objects according to its own laws. It appears to be employed in a like sense in the following extract from Glanvil—'Some say that the soul is not passive under the material phantasms; but doth only *intuitively* view them by the necessity of its own nature, and so observes other things in these their representatives.' (*Vanity of Dogmatising*, c. iv., p. 29.)

I'NULA, a genus of composite plants, one of whose species, I. Helenium, is used medicinally. This plant is a native of various parts of Europe, in pastures and woods; it has a thick bitter mucilaginous root, a stout stem three feet high, broad ovate serrated leaves, and large yellow flower-heads, which are solitary at the end of the ramifications.

I'NULA HELENIUM (Elecampane), an indigenous perennial herbaceous plant, found in moist meadows, the root of which is used in medicine. This part is thick and branching, brown externally, white internally, with an aromatic odour and a mucilaginous taste, at first bitter, afterwards sharp and camphor-like. In addition to mucilage and a large quantity of a variety of starch termed *inulin*, it contains a crystallized volatile oil (stearopten), a bitter extractive, an acrid resin, and some salts of lime, &c.

These ingredients give it a tonic and stimulating property, and it is employed in debility of the stomach, and other diseases of mucous surfaces unattended with inflammation. It is however not much used.

INULIN, a peculiar vegetable substance which is spontaneously deposited from a decoction of the roots of the *Inula Helenium*. It is a white powder, like starch, is insoluble in cold and soluble in hot water, from which it is deposited on cooling, and this distinguishes it from starch. With iodine it gives a greenish-yellow compound, which is not permanent. Inulin is distinguished from gum by its insolubility in cold water, and by not giving saccholactic acid when digested in nitric acid.

INVARIABLE (Mathematics), the same word in meaning as CONSTANT, which see. There are however two sorts of constants, which it is desirable to treat under different names: the first, which we may call a constant, or a common constant, meaning a quantity which is absolutely invariable: the second meaning a function which may vary, but which does not vary in the processes required by a given equation. This we propose to call the invariable function of that equation, or its invariable.

Thus, in a common differential equation, which is supposed to be true of y and x when x passes through all stages of magnitude whatsoever, the only invariable is an absolute invariable, or a common constant. But in an equation of differences, in which x only passes from one whole number to another, the invariable function is any one which remains unaltered by changing x from one whole number to another. Thus, [INTEGRATION, FINITE] instead of saying that the solution of $\Delta y = x + 1$ is $\frac{1}{2}(x^2 + x) + C$, where C is a constant, we may allow C to be any function of x, which is unaltered by changing x from one whole number to another. Such a function is $\phi(\cos. 2\pi x)$, so that the solution is $\frac{1}{2}(x^2 + x) + \phi(\cos. 2\pi x)$, and the last term is the invariable of the equation.

Again, suppose it required to solve the functional equation $\phi(x^2) = 2\,\phi x$. One solution of this is $\phi x = c \log x$, where c is any absolute constant. But the equation is solved if c be a function of x, provided it be one which does not change when x is changed into x^2. Such a function is

$$\cos. \left\{ 2\pi \frac{\log. \log x}{\log 2} \right\} \text{ or any function of it,}$$

$$\text{or } \phi x = \text{any function of } \cos. \left\{ 2\pi \frac{\log. \log x}{\log 2} \right\} \times \log x.$$

General methods of finding invariable functions, as far as they have yet been given, will be found in the 'Encyclopædia Metropolitana,' article 'Calculus of Functions.'

INVENTION. This term, when used in the language of art, has a different signification from what it usually bears in common language. It does not mean *discovery*, but combines *conception*, or the peculiar way in which an artist's mind takes cognizance of a subject to be represented, with the *mode of treatment*, or choice of objects and manner of disposing them best adapted for producing a desired effect. Thus, in painting and sculpture, it is the faculty by which the most perfect mode of illustration, by colour or by form, is suggested to the artist, and by which the mind of the spectator is led to comprehend the truth, the intention, and the whole purpose of the work before him; but so distinct is it at the same time from perfect execution, that it is often found to exist independently of excellence in that particular, some of the finest inventions in art being manifestly defective in technical requirements. It is therefore the highest quality in the constitution of the artist's mind; as Opie says, 'Destitute of invention, a poet is but a plagiary, and a painter a copier of others.' (*Lectures on Painting.*)

It is hardly necessary to enter into the question whether the power of invention be a primary and original law of the mind, or whether the effect of cultivation. Some have believed it may be a result of acquirements begun in youth, and carried on till the power is developed and perfected; others conceive that it is unatatinable by any human effort, and is part of the original constitution of the mind.

But even admitting invention to be a gift of nature, and not reducible to rule, nor to be taught by any regular process, it still may be improved by study. Whatever natural disposition or original capacity may exist—and it will not, we suppose, be denied that some minds are more bountifully endowed than others—every power short of *creation* must have groundwork and foundation *on* which and *out of* which to exercise itself; and even the inventive faculty, which seems to approach nearest to creation, depends upon knowledge, by whatever means acquired, for materials with which to develop and declare itself. Sir Joshua Reynolds

(*Discourses*) says, 'He who has the most materials has the greatest means of invention, and if he has not the power of using them, it must be from a feebleness of intellect;' and 'it is in vain to endeavour to invent without materials on which the mind may work,' &c.

Raffaelle, by the wonderful ability and power which he has shown in choosing subjects in which the greatest quantity of matter or incident could be introduced, and then in representing them at the most critical moment for illustration, in combining all the most striking and affecting circumstances, and filling the spectator's mind with the whole story, by bringing before him, as it were, the past, the present, and even suggesting that which is to follow, may justly be considered the greatest master in invention. He was gifted, if any man ever was, with the fullest portion of natural and inherent genius, but he attained his eminence by the most persevering course of exercise and observation, as the necessary and only means through which the inventive faculty could be manifested. He studied nature diligently and profoundly in all her varieties of beauty and expression. Nothing seems to have escaped him; everything that offered itself out of her great storehouse was treasured as serviceable to his art, and he acquired such an accumulation of materials, serving as handmaids to his invention, that whatever subject came before him found him prepared, and was immediately dignified with all the expression, truth, propriety, and completeness, if we may use the word, that it was capable of receiving. Raffaelle never reached the perfect beauty and character almost superhuman which appear in the finest works of the Greeks, nor, in colour, the magic brilliancy and breadth of Titian, another master-spirit; yet, in the largest and most comprehensive sense of the quality we have been describing, he stands (perhaps with one mighty exception) without an equal or a rival.

The examples which may be most satisfactorily adduced in illustration of invention in the fine arts, both for their excellence and for the facility of reference, as we are so fortunate as to possess them in this country, are the Cartoons of Raffaelle preserved at Hampton Court. Of these the 'Paul preaching at Athens,' 'The Sacrifice at Lystra,' and 'The Death of Ananias,' may be selected as the most remarkable for the quality we have been considering.

Equally admirable, though totally in a different style, the frescoes of Michael Angelo, in the Sistine Chapel at Rome, must be quoted as triumphs of invention, a proud achievement of the human mind. The comprehensiveness of his scheme of illustration, with the greatness and energetic character of his design and composition, render this one of the finest monuments that art has to boast. In viewing the magnificent works of these two masters, namely, of M. A. Buonarotti, in this chapel, and of Raffaelle d'Urbino, in the loggie and stanze of the same palace (the Vatican), the spectator has a series of examples of as wonderful efforts of inventive genius in historical design as it seems possible to produce. The works of Rubens offer also fine examples of invention, though the quality of his design, or rather of his forms, was not according to a classical or pure standard.

It should be observed here that invention is quite independent of the *class* of design; its force and power may be displayed in every part of the art, and in subjects of inferior grade, or even in the mode of treating colour, light, and shade. Rembrandt, to proceed with further illustration, is one of those who displayed very high powers of invention; 'a genius,' Fuseli says, 'of the first class in whatever relates not to form;' and he justly eulogises his 'powers of nature' and 'the grandeur, pathos, and simplicity of his composition.' Thus also, though the quality of his art was not of the highest or grand class, the merit of invention is eminently due to our own Hogarth. Opie, in speaking of this artist, alludes in terms of high admiration to a fine example of invention in one of his pictures of the series called 'The Rake's Progress.' In the bagnio scene he has introduced in the back-ground one of the dissolute women of the party setting fire to a map of the World.

We have referred only to a very few out of the numerous artists whose works are worthy of attention as examples of invention; and have confined ourselves to some of the leading painters, though we might easily multiply them from productions in the sister art. Enough however has been said to point out the nature and value of that high quality in design, and to enable the intelligent observer to recognise and appreciate it when he meets it in the productions of artists, and discriminate between the efforts of elevated and original minds and the commonplace performances of mere mechanical copiers. Invention is required in every branch of art to raise it above tameness and insipidity: it is indeed the magic power by which works of art first attract and then fix the attention.

It is hardly necessary to observe, that, difficult as it may be to prescribe bounds to the imagination or the power of invention, it has in art certain and defined limits beyond which the painter and sculptor should not attempt to venture. When the artist dashes into extravagance, defies or outrages nature, and, with a view of exciting wonder, steps out of the region of what is, has been, or may be, he only shows that he has been gifted with fancy, but that it is wild and ill-regulated; he may awaken surprise, and may mistake it for admiration, but he will produce no lasting nor beneficial impression, and his undisciplined fantasy will never deserve to be ranked with the genius that has nobly illustrated nature by the only just, safe, and legitimate means, namely, her own beautiful, and expressive, and perfect works.

INVENTORY. [EXECUTOR.]

INVERARY, a royal burgh and seaport, capital of the county of Argyle, situated on a small bay at the head of Loch Fyne, where the river Aray falls into that arm of the sea, 75 miles west by north from Edinburgh. The town was erected into a royal burgh by charter granted by Charles I. and dated 28th January, 1648. (*Municipal Corporation Reports.*) The whole territory, with the exception of a small feu, is the property of the Duke of Argyle, of whom the inhabitants hold their houses and grounds either under leases or as tenants at will. It is governed by two baillies and nine common-councillors. The annual income of the burgh is about 180*l.* and the annual expenditure is somewhat less. The town consists chiefly of one row of houses facing the bay, built with great uniformity and covered with slate. The arrangements for watching, cleaning, lighting, and the supplying of water are confided to the town council, and the expenses are defrayed from the proceeds of the burgh manure. The inhabitants are principally engaged in the herring-fishery in Loch Fyne, which is said to have produced in some seasons upwards of 20,000 barrels. (*Beauties of Scotland*, vol. v., p. 437.) The grammar-school is superintended by a teacher, whose salary is 20*l.* The number of scholars during the last 10 years has varied from 25 to 30 annually. The population of the burgh and parish in 1831 was 1117.

Inverary Castle, the principal seat of the Duke of Argyle, is situated near the northern extremity of Loch Fyne. It is a quadrangular building, with a tower at each corner, and a high glazed pavilion rising from the centre of the roof. The stone of which it is constructed, though soft, is very durable, and becomes perfectly black when wetted by a shower. The spacious hall, which is hung with arms and other ornaments, is lighted by a lofty window, and surrounded by a gallery. The other apartments are fitted up in a modern style and with good taste. (*Parliamentary Papers; Beauties of Scotland*, &c.)

INVERNESS, a seaport town and royal burgh of some antiquity, the capital of the county of Inverness, and the principal town of the Highlands. It is situated at the southern extremity of the Moray Frith near the eastern entrance of the Caledonian Canal, 155 miles north by west from Edinburgh. The earliest charters upon record are those of King William the Lion, four in number, conferring several privileges upon the burgesses, which were confirmed and extended by the subsequent charters of Alexander II., III., Robert I., David II., James II., Queen Mary, and James VI. The last constitutes the governing charter of the town, and is dated [illegible] January, 1591. (*Municipal Corporation Reports.*) The management of the affairs of the burgh is vested in a provost, three baillies, and 15 town councillors. In 1832 the estimated value of the burgh property, consisting principally of lands and other heritable property, was 20,811*l.*, producing an annual revenue of 2236*l.* The annual expenditure at the same period was 2058*l.*, and at Michaelmas 1833 the aggregate debt was 10,614*l.* The town is large and well built; the houses are lofty, and many of them elegant. The streets have, since 1831, been paved with granite and hard sandstone brought from the banks of Loch Ness. Common sewers have been constructed, and the town is well lighted with gas, and supplied with water by means of pipes from the adjacent river. The system of police is also described

as most efficient. The public buildings consist of three national churches, an Episcopalian church, a court-house, and Tolbooth. The last is a handsome modern building with a fine tower terminated by a very elegant spire. The central school-house, situated upon the Green of Muirtown, is also a fine building, and comprises a large public hall, with six spacious apartments for the accommodation of the different classes and for the library and philosophical apparatus. Inverness is the centre of the custom-house district, which extends from the mouth of the Spey to Dornoch Frith on the east coast, and from Assynt Point to Ardnamurchan on the west. 'A striking alteration has of late taken place in the trade of grain; within fifteen years about 8000 to 10,000 bolls of oatmeal used to be imported annually into Inverness; while now from 4000 to 5000 bolls of oats are exported from its piers. . . . . The foreign annual imports into Inverness consist of from 400 to 600 tons of hemp, and three or four cargoes of timber or Archangel tar.' (*New Statistical Account of Scotland.*) There is no compulsory assessment for the support of the poor, who are provided for by special quarterly collections, by several charitable mortifications at the disposal of the magistrates, and from other sources. A short account of schools, which are numerous and upon the whole well conducted, is given in the article INVERNESS-SHIRE. The population of the burgh and parish of Inverness in 1831 was 14,324. The people in Inverness speak very good English: the tradition is that they learned it from Cromwell's soldiers. The climate of Inverness is much milder than might be supposed from its northern position in the island. Its mean annual temperature is about 47°, while that of the neighbourhood of London is about 48·5°, and that of London 50·5°. The mean annual quantity of rain which falls at Inverness is about 26·21 inches. This borough unites with Fortrose, Nairn, and Forres in returning one member to parliament.

INVERNESS-SHIRE, a maritime county of Scotland, bounded on the north by Ross-shire, on the south by the shires of Perth and Argyle, on the east by those of Nairn, Elgin, Banff, and Aberdeen, and on the west by the Atlantic Ocean; the mainland is comprised between 56° 40′ and 57° 36′ N. lat., and between 3° 50′ and 5° 50′ W. long. from Greenwich. Its greatest length from north-east to south-west is 88 miles, and its greatest width from north-west to south-east nearly 55 miles. According to Mr. M'Culloch (*Statistical Account of the British Empire*) the entire county contains 4245 square miles, or 2,716,800 acres, of which the mainland occupies 1,943,920, and its islands 773,760; the former having 84,480, and the latter 37,760 acres of water. It comprehends various districts, particularly that of Badenoch on the south-east, where it borders upon Perth and Aberdeenshire; Lochaber on the south adjoining Argyleshire; Glenelg on the north-west bordering upon the ocean; besides many inferior districts, such as Glengary, Glen Morrison, Glenshiel, &c. It also comprehends a considerable portion of the Hebrides, or Western Isles, including the Isles of Skye, Harris, Benbecula, North and South Uist, Barra, &c. [HEBRIDES.] This county, which is extremely mountainous, is intersected by innumerable lakes and rivers, and is divided into two nearly equal parts by the deep valley of Glenmore, which runs in a direction from Fort William on the south-west to the town of Inverness on the north-east. This county forms a large part of the Highlands of Scotland, and the general description of its geographical features cannot well be separated from that of the division of the island to which it belongs. [GREAT BRITAIN, p. 402.] By far the greater part of the surface is covered with heath, but a good deal of the heathy ground is arable, and a considerable extent of it has been brought into cultivation during the present century. The population in 1831, according to the population returns for that year, was 94,797, of which 44,510 were males, and 50,287 females. The valued rent at the same period was 73,188*l.* Scotch, but the annual value of real property in 1815 was 185,565*l.* The county sends one member to parliament. [INVERNESS.]

Geology and Mineralogy.—The prevailing rocks are of the primary class, having a highly crystalline structure, and being entirely destitute of organic remains. Gneiss is perhaps the most abundant, but huge masses of granite and of the oldest trap or porphyritic rocks are met with in the Grampians and the mountains of Glencoe and Ben Nevis. Limestone is found in several districts, and approaches to the nature of marble, particularly near Ballachulish and in the bed of the river three miles south of Fort William. Sandstone is also frequently met with. The beds of the stratified rocks are usually highly inclined to the horizon, approaching almost to the vertical, but the dip varies. Their general direction is from south-west to north-east. The two principal mountains are Ben Nevis and Mealfourvounie. The former, which is separated from the Grampians by the desolate tract called the Moor of Rannoch, is composed of porphyry and granite, and rises 4374 feet above the level of the sea, being the highest mountain in Great Britain. It is easily ascended on the western side; and at about the height of 1500 feet the prospect, till then confined, opens to the south-west and discovers the Paps of Jura and several of the Hebrides. Above the altitude of 2000 feet there is no vegetation, and on the north-east side of the mountain, near its summit, the snow lies throughout the year. Mealfourvounie, which rises 2730 feet above the sea-level, is composed of a conglomerate rock and stratified sandstone, the latter of which is of so hard a texture as to be used for the pavements of the streets of Inverness. Some veins of lead and silver have been discovered in several parts of the county, and also iron ore in small quantities, but we are not aware that mines have hitherto been worked to any extent. The soil is for the most part light and sandy, with a subsoil of gravel or clay; but in the neighbourhood of the town of Inverness it is enriched by a fine loam deposited by the waters of the adjoining frith.

Farms, Estates, and Agriculture.—In 1808 the landed property of this county was divided among 83 proprietors, viz. 7 estates of the valued rents of 3000*l.* per annum (Scotch); 6 from 1000*l.* to 3000*l.*; 23 from 400*l.* to 1000*l.*; 33 from 100*l.* to 400*l.*; and 14 under 100*l.* From that period to the present time we believe the above distribution has not undergone any material alteration. Formerly there were a great number of small arable farms only a few acres in extent, but these have much decreased since the introduction of sheep-farming. What remain of them are usually let from year to year, but the larger farms are let on lease, varying from seven to nineteen years. The farm-houses erected within the last forty years by the wealthier class of store farmers are for the most part well constructed, but the dwellings of the cottagers and poorer tenants are described as being in every respect comfortless and mean. (McCulloch's *British Empire*, vol. i., p. 310.) The attention of the farmers is chiefly directed to the rearing of sheep and cattle. The sheep are mostly of the Cheviot and Linton breeds, and the stock at the present time is estimated at 120,000; the stock of cattle is supposed to amount to 40,000 or 45,000, and is chiefly of the Skye or Kyloe breed. In the month of July a fair for the sale of sheep is held annually at the town of Inverness, where, upon an average, 100,000 sheep and as many stones of wool are bought up for the southern markets. The labourers and farm-servants generally live on potatoes with milk, and oats and barleymeal prepared in various ways, to which the wealthier tradesmen are able to add fish and butcher's meat. The usual rate of ploughmen's and farm-servants' wages is 8*l.* in money and six bolls of meal, with liberty to plant as much ground with potatoes as they can manure, and female labour is commonly reckoned at two-thirds that of men. The fields are frequently enclosed, and within the last twenty years a great deal of waste land has been drained and reclaimed, and much ground planted; but none of any consequence has been irrigated or embanked. The average rent of cultivated ground varies from 1*l.* to 2*l.* 10*s.* the acre, but in the immediate vicinity of the town of Inverness it is as high as 5*l.* to 7*l.* the acre.

Forests.—The fir woods in Glenmore and those of Strathspey in the adjoining county of Elgin are supposed to be more extensive than all the other natural woods in Scotland together. 'Glen Morrison, which opens into Glenmore, also contains much fine timber. In the parish of Kilmalie alone, near Fort William, it is estimated that there are about 14,000 acres covered with trees. Those which grow naturally are the oak, fir, birch, ash, mountain ash, holly, elm, hazel, and the Scotch poplar. Those which are planted are the larch, spruce, silver fir, beech, plane, and fruit trees. In these forests and the neighbouring mountains the herds of red and roe-deer roam in safety in recesses almost impenetrable to man. The alpine and common hare and other game are also abundant.

Manufactures.—Formerly a good deal of hemp, worsted,

and linen yarn was made in this county, but this has greatly declined since the establishment of the large manufactories of the south. At the present time there is a hemp manufactory employing nearly 300 hands, and a woollen factory for the weaving of coarse clothing and Highland plaids and tartan. The produce of the former is principally exported to the London market and to the East and West Indies.

Inland Navigation and Roads.—The Glenmore, or 'Great glen of Albion,' as it is sometimes called, which stretches across the county from Fort William to the town of Inverness, is partially covered by three lakes, Loch Lochy, Loch Oich, and Loch Ness, which lie nearly in a straight line between the above-mentioned limits. Their aggregate length is 37 miles 704 yards, and the entire distance between Fort William and Inverness is 59 miles and 1628 yards. In 1802 Mr. Telford was appointed by the commissioners of the treasury to make a survey of these lakes and of the adjoining country preparatory to the cutting of a canal. His report was made in the following year, and the works were in full operation in 1805, but the whole line of navigation was not opened till the latter end of the year 1822. The expense of constructing the Caledonian Canal, as it is called, was defrayed by government. That part of the navigation which is not upon the lakes is 22 miles and 1628 yards in length: it is 50 feet wide at the bottom and 15 feet deep, though the original plan contemplated a depth of 20 feet. Loch Oich is the summit-level of the canal, and its elevation is 94 feet above the level of the sea on the east coast, at high water and ordinary spring tides. The entire cost was 986,924*l.*, to which must be added a portion of the annual expenditure since the opening of the navigation, which has hitherto exceeded the produce of tonnage dues. The tonnage dues on vessels, whether laden or unladen, is one farthing per ton per mile, and produced in 1829 a revenue of 2575*l.*; but the expenditure during the same year amounted to 4573*l.*, so that this canal promises to be but an unprofitable speculation. 'Its chief effect, as regards the town of Inverness, has hitherto been the commencement and gradual formation of a direct intercourse with the great western marts of Glasgow and Liverpool, and, through them, with the manufacturing districts with which these cities are so closely connected.' (*New Statis. Acct.*) The roads are under the management of the Parliamentary Commissioners for Highland Roads —a body appointed for opening the communication by land about the same time that the Caledonian Canal was projected. They are said to be maintained in a state of most efficient repair, the expense being defrayed partly by government and partly by contributions from the county proprietors. The principal rivers are the Spey, Ness, and Beauly; in all of which there are valuable salmon fisheries, more particularly upon the Spey and Ness.

Education, Schools, &c.—Upon the formation, in the year 1818, of the 'Society for Educating the Poor in the Highlands,' a central or model school was erected on a large scale in the town of Inverness. This establishment, as might be expected, has already proved highly beneficial to the poor of the town and suburbs, and is upon an average attended by about 300 scholars. The same society supports twelve other similar institutions of less extent in the more remote and thinly peopled part of the Highlands, and from its first establishment in 1818 to the 30th of September, 1834, its total expenditure amounted to 8023*l.* The Raining School, founded in 1747 by Mr. John Raining of Norwich, and endowed by that gentleman with the sum of 1000*l.*, is superintended by two well qualified teachers, having salaries of 48*s.* and 40*l.* per year, together with a house and garden. The number of pupils is usually about 250. In addition to these, there are several private elementary schools, besides Sabbath evening-schools for religious instruction, which are attended by a very considerable number of children. 'Inverness, thus already more amply provided than many other towns with the means of education and improvement, has been further enriched by a munificent bequest of 10,000*l.* 3 per cent consols, left by the late Rev. Dr. Bell, the ingenious author of the Madras System of Education, and committed by him to the charge of the magistrates of Inverness, who contemplate, we understand, erecting another large charity-school, and relieving the Education Society of the burthen of supporting their central or model school on the Green of Muirtown.' (*New Statistical Account.*)

The parochial schools throughout the county are numerous and increasing, and the reader will find a very satisfactory description of their present state under the head of the several parishes in the above-cited work.

(*New Statistical Account of Scotland;* Playfair's *Description of Scotland; Beauties of Scotland;* Society's *Map of Scotland; Parliamentary Reports on the Caledonian Canal,* 1803-4-5-6; *Parliamentary Papers,* &c.)

INVERSE, INVERSION. Any two operations of algebra are said to be inverse when one of them undoes, so to speak, the effect of the other; so that if both be successively performed upon the same quantity, the result is that quantity itself. For instance, the operations implied in $1+x^2$ and $\surd(x-1)$ are inverse to one another; for

$$1+\{\surd(x-1\}^2=x, \qquad \sqrt{(1+x^2}-1)=x.$$

We need do no more than name addition and subtraction, multiplication and division, raising of powers and extraction of roots, as pairs of inverse operations.

The operation of inversion is the solution of an equation, and *vice versâ*. Let it be required to find the operation inverse to ϕx. Assume $\phi x=y$, and find x in terms of y; say $x=\psi y$, then $\phi(\psi y)=y$, or ϕ and ψ are inverse operations. Thus if $x^2-2x=y$, $x=1\pm\sqrt{y+1}$, and either of the two, $1+\sqrt{x+1}$, or $1-\sqrt{x+1}$, is inverse to x^2-2x.

It thus appears that a function may have more than one inverse function, and there are functions which have an infinite number; but there is a distinction by which one may be separated from all the rest. Let the Greek letters in this article be all functional symbols, or marks of operations to be performed, and let them come before the subject of operation, the quantity x, or y, &c., in the order in which they are to be performed. Thus $a\phi x$ denotes the result of performing the operation ϕ upon x, and then the operation a upon ϕx. Now let $\phi x=z$ give $x=\psi z$, where ϕx is an unambiguous operation, and ψz is, generally speaking, ambiguous, or presenting several different forms. Then ϕ and ψ are inverse operations, and $\phi\psi z=z$, and we might suppose at first that $x=\psi\phi x$; that is to say, we might imagine that ψ destroys ϕ as well as that ϕ destroys ψ. But since ψ is ambiguous, it may be that only one or more of the forms of ψ will satisfy $x=\psi\phi x$, and not all: and that this will be the case with one is obvious, while we can show that it cannot happen with more than one. For though the same operation, performed on different functions, may produce the same function, yet different operations, performed on the same function, must produce different functions. If then a and β be different forms of ψ, we have $\phi a x=x$ and $\phi\beta x=x$; but we cannot have both $a\phi x=x$ and $\beta\phi x=x$, where a and β are different, ϕx having absolutely the same form and value in both equations.

From all the inverses of a function ϕx, then, we separate that one, ax, which gives both $\phi a x=x$ and $a\phi x=x$, and call it the *convertible* inverse. Its symbol is ϕ^{-1}, so that $\phi^{-1}x$ means that operation which satisfies both the equations $\phi\phi^{-1}x=x$ and $\phi^{-1}\phi x=x$. [EXPONENT.] In the preceding example $1+\surd(x+1)$ is the convertible inverse of x^2-2x: for $1+\surd(x^2-2x+1)=1+x-1=x$. But $1-\sqrt{x^2-2x+1}$ gives $1-(x-1)$ or $2-x$; and we call this an inconvertible inverse.

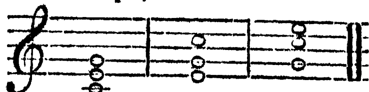
Every function which has more than one inverse is not only a function of x, but the same function of other functions of x. Let $a\,x$ be an inconvertible inverse of x; then $a\phi x$ is not x, let it be ϖx. Then $\phi a x$ being x, $\phi a\phi x$ is ϕx, or $\phi\varpi x$ is ϕx, so that ϕx is the same function of ϖx which it is of x. Thus in the preceding example x^2-2x is the same function of $2-x$ which it is of x; or

$$x^2-2x=(2-x)^2-2(2-x).$$

We have then this theorem: every function has as many different forms as inverses, and all these forms can be made by writing different functions of x instead of x in the original function; and each inverse of the function is the convertible inverse to one of its forms, and an inconvertible inverse to all the rest. Thus $1-\surd(x+1)$, which is an inconvertible inverse to x^2-2x, is the convertible inverse of $(2-x)^2-2(2-x)$: for

$$1-\surd\Big((2-x)^2-2(2-x)+1\Big)=1-(2-x-1)=x.$$

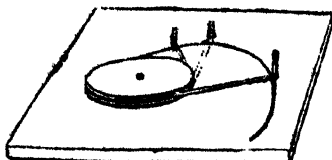
The way to make the convertible inverse of a given func-



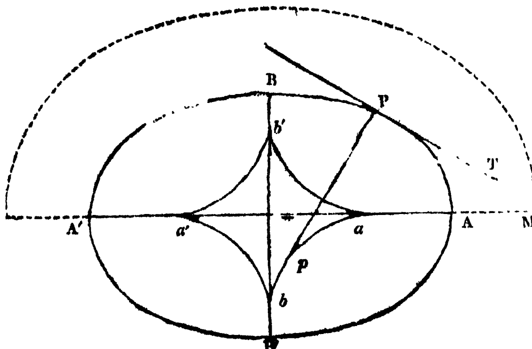
tion find all the rest is as follows. Find the solutions of the equation $\phi \varpi x = \phi x$, and let them be $\varpi_1 x, \varpi_2 x$, &c. Then $\phi^{-1} x$ being the convertible inverse of ϕx, the remaining inverses are $\varpi_1 \phi^{-1} x$, $\varpi_2 \phi^{-1} x$, &c. Thus in the preceding example $\phi^{-1} x$ being the convertible inverse, the other is $2 - \phi^{-1} x$. [PERIODIC FUNCTIONS.] There is a remarkable class of functions, each of which is its own inverse, such as $1-x$, $\frac{1}{x}$, $\surd(1-x^2)$, &c. Now if $\phi x = \phi^{-1} x$ we have $\phi \phi x = x$, and these functions will be considered, in the article just cited, as periodic functions of the second order.

The equation $\phi \phi^{-1} x = x$ being understood, suppose that between the first and second operations we interpose the operation a, so that we have $\phi a \phi^{-1} x$. This is no longer equal to x, but it is a function, the properties of which are closely connected with those of $a x$. For instance, if $a x$ and βx be inverse to each other, then $\phi a \phi^{-1} x$ and $\phi \beta \phi^{-1} x$ are also inverse to each other: for $a \beta x = x$ and $\phi a \phi^{-1}\left(\phi \beta \phi^{-1}\right) x$ is $\phi a \phi^{-1} \phi \beta \phi^{-} x$, or $\phi a \beta \phi^{-1} x$, or $\phi \phi^{-1} x$, or x. Thus knowing $x + 1$ and $x - 1$ to be inverse functions, we know immediately that $\log(\epsilon^x + 1)$ and $\log(\epsilon^x - 1)$ are inverse functions; and also $\surd(x^2 + 1)$ and $\surd(x^2 - 1)$. For more detail on this subject see the article 'Calculus of Functions,' in the 'Encyclopædia Metropolitana.'

INVERSION, in Music, is a change in the relative position of two sounds, or of the several notes of a chord. Thus C D, an interval of a 2nd, becomes by inversion (D C) a 7th. Example,—



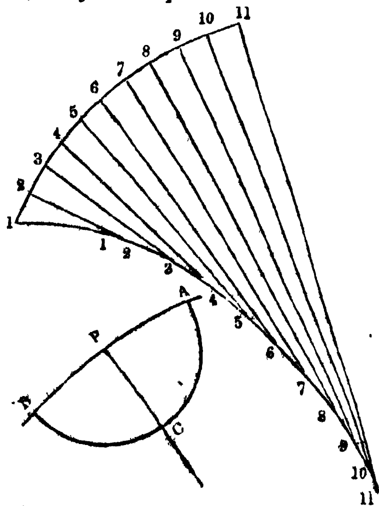
And C E G, the notes of the triad, or perfect chord, by inversion become the chord of the 6th (E G C), or of the 4th (G C E). Example,—



For other musical Inversions, see CANON and FUGUE.

INVOLU'CRUM, in botany, is any collection of bracts round a cluster of flowers. In umbelliferous plants it consists of separate narrow bracts placed in a single whorl; in many composite plants these organs are imbricated in several rows. If the bracts belong to a secondary series of the inflorescence, as in the partial umbels of an apiaceous plant, or in the solitary florets of Echinops, they form an involucel. The most singular state of the involucrum is that which is found in the genera Castanea, Fagus, Quercus, &c., where it forms a cup, or closed cover, remarkable in the European species of those genera, but much more so in the species of India.

INVOLUTE AND EVOLUTE (the curve unrolled and the curve from which it is unrolled), a name given to two curves so formed and placed, that supposing the second to be cut out from solid matter, the first can be formed by fastening one end of a thread upon a point in the second, attaching a pencil to the other end, and moving the pencil so that the thread may either gradually enwrap or be unwrapped from the curve to which it is fastened. Thus the pencil in the diagram is describing the involute of a circle, or the curve of which the circle is the evolute. But the evolute of a circle is evidently a point.



The following figure represents an ellipse with its evolute. If the thread be fastened at b, wrapped over $b a$, and continued to A, it will, as it unwraps from $a b$, describe the arc A B; and B A′ while it wraps over $b a'$. If fastened in a similar manner at b', it will by the same process describe A B′A′.

If the line p P be drawn tangent to the evolute at p, it is one of the positions of the thread, and P T, the tangent of the involute at P, is perpendicular to p P. Also p P is the radius of curvature of the involute at P; this is to say, no circle can pass so near the curve at P, as the one which has p for its centre and p P for its radius. [CURVATURE.] Also, any arc of the evolute is the difference of two radii of curvature of the involute: thus the arc $a p$ is the difference between a A and p P. Such are the principal geometrical connexions of the two curves.

Every curve has one evolute, and an infinite number of involutes. For instance, fastening the thread at b, and continuing it to M instead of A, we may with the cheeks $a b$ and $b a'$ produce another involute from them (represented by a dotted line); and any number, however great, by varying the position of M. But none of these involutes will be ellipses, except the one from which the evolute was made; though they will all be ovals having remarkable analogies with the ellipse. The proper name for curves described from the same evolute is *parallel curves*, since they have the fundamental property of parallel lines: for they never meet, though (if they admit of it) ever so far produced; a straight line perpendicular to one is always perpendicular to the other; and the part of the perpendicular intercepted is always of the same length. When arcs of parallel curves are required to be laid down, the most commodious method of proceeding is to construct the evolute of one of the arcs approximately, as follows. On the arc draw tangents at moderately small distances, and draw perpendiculars to those tangents. The parts of the tangents cut off from each by its neighbours will together give the arc of the evolute near enough for all purposes. And it may be well to notice that it will be a sufficiently accurate method of drawing the perpendicular to the tangent at a point P, if we take a small circle whose centre is P, bisect the arc A C B in C, and join and produce P C.

The angular error thus committed is only a small portion of the angle made by the tangents at P and A.

Whenever the two arcs adjacent to a normal (or perpendicular to the tangent) of the involute are equal and similar, there is a cusp in the evolute; and the evolute generally recedes without limit as we approach a point of contrary flexure in the involute.

The mathematical method of finding the evolute is as follows. Let $y=\phi x$ be the equation of the involute, and let X and Y be the co-ordinates of the point on the evolute corresponding to that on the involute whose co-ordinates are x and y. Form the three equations—

$$y=\phi x;$$
$$X-x+\frac{dy}{dx}(Y-y)=0;$$
$$1+\left(\frac{dy}{dx}\right)^2-\frac{d^2y}{dx^2}(Y-y)=0;$$

and from them eliminate x and y. The resulting equation between X and Y is that of the evolute. But if the evolute be given, and the involute is to be determined, let $Y=fX$ be the equation of the former, and from this and the latter two of the preceding three equations eliminate X and Y. There will result a differential equation of the second order between y and x, the primitive of which is the equation of the involute, the two arbitrary constants being determined by the point at which the thread is supposed to be fixed and the length of the thread.

Thus if the curve be a parabola having the equation $y=cx^2$, the equations for determining the evolute are—

$$y=cx^2;$$
$$X-x+2cx(Y-y)=0;$$
$$1+4c^2x^2-2c(Y-y)=0;$$

from which we find—

$$X=-4c^2x^3, \qquad Y=\frac{1}{2c}+3cx^2;$$

which give $Y=\frac{1}{2c}+\frac{3}{2}\left(\frac{X^2}{2c}\right)^{\frac{1}{3}}$,

the equation of the evolute of the parabola, which evolute therefore appears to be what is called a *semi-cubical* parabola.

For considerations similar to those which precede see CAUSTICS.

INVOLUTION and EVOLUTION. (Arithmetic.) Taking these words in their etymological sense, they might stand for the greater part of mathematical analysis. In their technical algebraical sense, they mean only the raising of powers, and the inverse operation, the extraction of roots. The revival however of a general process, accompanied by an improvement which makes it comparatively easy, renders it necessary to make a more extensive definition of the terms. We shall not relinquish any characteristic of the old meanings, and shall bring all corresponding processes together, by laying down the following definition:—Involution is the performance of any number of successive multiplications with the same multiplier, interrupted or not by additions or subtractions; and evolution is any method of finding out, from the result of an involution, what multiplier was employed, provided that the said method proceeds by involutions. Thus to determine $2x^3+4x^2-3x+10$ by involution, we multiply 2 by x, and add 4; then multiply by x and subtract 3, then multiply by x and add 10. If this give 1000, then any method of determining x which proceeds by successive involutions is evolution.

A few years ago our only instances of evolution would have been common division, and the extraction of the square and cube roots, with references to Vieta, Harriot, Oughtred, and the older algebraists in general, for evolutionary methods of solving equations, bearing a strong likeness to such extractions. But since the publication of Mr. Horner's 'New Method of solving Equations of all orders,' *Phil. Trans.*, 1819, the process which has rendered it worth while to propose the preceding extension of terms has been in the hands of mathematicians. For a more detailed account than we can here give, the reader is referred to the paper just cited, which is reprinted in the 'Ladies' Diary' for 1838, or to 'The Theory and Solution of Algebraical Equations,' by Professor Young of Belfast (London, J. Souter, 1835).

We should begin with simple division, and the extraction of the square and cube roots, if we were writing an elementary treatise. But taking it for granted that the reader is familiar with the first two, at least, we shall proceed to describe the general process. This consists of three distinct parts, the first two of which have been long known, while the third, which contains the peculiar distinction of this method, is due to Mr. Horner.*

1. In the article APPROXIMATION it is shown that if a be a value of x which makes ϕx very small, then $a-(\phi a \div \phi' a)$ is a value of x which makes ϕx much smaller; so that a continued succession of approximations may be made to a value of x which makes ϕx absolutely $=0$. Here ϕx means the differential coefficient or derived function and if

$$\phi x = Ax^n + Bx^{n-1} + Cx^{n-2} + \ldots\ldots \quad ; \text{ then}$$
$$\phi' x = nAx^{n-1} + (n-1)Bx^{n-2} + (n-2)Cx^{n-3} + \ldots.$$

2. Meaning by a root of ϕx, any value of x which makes $\phi x=0$, it is obvious that $\phi(x+a)$ is a function which has for its roots the roots of ϕx, each diminished by a. And the substitution of $x+a$ instead of x in the preceding value of ϕx gives a well known development, of which an instance will be more to our present purpose. Let the function be

$$Ax^5+Bx^4+Cx^3+Dx^2+Ex+F \ldots. \; (1).$$

Write $x+a$ for x, and this becomes

$$Ax^5+(5Aa+B)x^4+(10Aa^2+4Ba+C)x^3$$
$$+(10Aa^3+6Ba^2+3Ca+D)x^2$$
$$+(5Aa^4+4Ba^3+3Ca^2+2Da+E)x$$
$$+Aa^5+Ba^4+Ca^3+Da^2+Ea+F;$$

which we may represent by

$$Ax^5+\phi_4 a\, x^4+\phi_3 a\, x^3+\phi_2 a\, x^2+\phi' a\, x+\phi a.$$

3. The quantities ϕa, $\phi' a$, $\phi_2 a$, &c. may be determined by a succession of involutions, each one making use of the results of the preceding. Find ϕa by involution, of which the following are the steps:—

$$A$$
$$Aa+B$$
$$Aa^2+Ba+C$$
$$Aa^3+Ba^2+Ca+D$$
$$Aa^4+Ba^3+Ca^2+Da+E$$
$$Aa^5+Ba^4+Ca^3+Da^2+Ea+F=\phi a$$

Repeat the process, using the preceding quantities, except the last, and we have $\phi' a$ by the following steps:—

$$A$$
$$2Aa+B$$
$$3Aa^2+2Ba+C$$
$$4Aa^3+3Ba^2+2Ca+D$$
$$5Aa^4+4Ba^3+3Ca^2+2Da+E=\phi' a.$$

A repetition of the process, leaving out the last, gives $\phi_2 a$, as follows:—

$$A$$
$$3Aa+B$$
$$6Aa^2+3Ba+C$$
$$10Aa^3+6Ba^2+3Ca+D=\phi_2 a.$$

Repetition gives $\phi_3 a$, and finally $\phi_4 a$, as follows:—

$$A \qquad\qquad\qquad A$$
$$4Aa+B \qquad\qquad 5Aa+B=\phi_4 a$$
$$10Aa^2+4Ba+C=\phi_3 a$$

In numerical application the operations may be made to stand thus, where a new letter below a line stands for the sum of the two preceding; and ϕa, $\phi' a$, &c. are introduced when found.

A	B	C	D	E	F
	Aa	Pa	Qa	Ra	Sa
	P	Q	R	S	ϕa
	Aa	Ta	Ua	Va	
	T	U	V	$\phi' a$	
	Aa	Wa	Xa		
	W	X	$\phi_2 a$		
	Aa	Ya			
	Y	$\phi_3 a$			
	Aa				
A	$\phi_4 a$	$\phi_3 a$	$\phi_2 a$	$\phi' a$	ϕa

If a be of only one significant figure (as 200, 6, ·03), all the operations necessary to fill up this process can be performed in the head, and we have thus (for the method is general, though our example be only of the fifth degree) a working

* Mr. W. G. Horner was a schoolmaster and mathematical teacher residing at Bath, and died September 29, 1837. His works are announced as in preparation for the press, under the superintendence of Professor Davies, of the Royal Military Academy.

There has been some dispute about the right to the invention, of which we do not here speak in detail, as we have no doubt it will be extremely evident to all who examine the question that Mr. Horner is the first author and publisher (and, we believe, the only one) of that particular part of the method which goes beyond Vieta and his successors. (See 'Companion to the Almanac' for 1839.)

method of answering the following question:—Given a certain equation $\phi x = 0$; required the equation $\psi x = 0$, the roots of which are each less by a than those of $\phi x = 0$.

If ϕa came out $= 0$, we should then know that a is a root of the equation: and the method of approximating to a root is as follows:—Suppose we have an equation of which the root (unknown to us) is 26·73. By trial, or otherwise, suppose we find that 20 is the highest denomination of the root, and we thereupon find another equation, each of whose roots is less by 20 than a root of the given equation: this is done by the preceding process, and one of the new roots (but unknown) is 6·73. If we can find that the highest denomination of this root is 6, we make another reduction of all the roots, and find a new equation, one of whose roots is ·73. If we can then find ·7 to be the highest denomination, we repeat the process and find an equation one of whose roots is ·03. In finding the highest denomination of this root we find the root itself, evidenced by the ϕa of this final process being $= 0$.

The first denomination of the root must be found by trial, or by some of the methods referred to in THEORY OF EQUATIONS. But the second and the remaining ones are found by comparing the results ϕa and $\phi' a$. If a be nearly a root,

$$a - \frac{\phi a}{\phi' a} \text{ or } a + \frac{-\phi a}{\phi' a}$$

is still nearer. Consequently, by dividing $-\phi a$ by $\phi' a$, we may, after the second process, be sure of finding one figure of the remaining root correct. But after the first process we may be liable to an error of a unit (to be corrected by a new trial), as in extraction of the square root.

In order to obtain $-\phi a$ and not ϕa, let the last coefficient, F, have its sign changed, and let the process in the column which contains it always be subtraction, and not addition. In the preceding type of calculation, we should then have

$$\begin{array}{c} -\mathrm{F} \\ \underline{\mathrm{S}a} \\ \text{Subtr.}\ -\phi a \end{array} \quad \text{instead of} \quad \begin{array}{c} \mathrm{F} \\ \underline{\cdot \mathrm{S}a} \\ \phi a\ \text{Add.} \end{array}$$

In carrying on the process, the results ϕa, $\phi' a$, &c. come in a diagonal line; before taking the next step, the beginner should bring them down into one line, as in the type preceding. In our examples, asterisks or other symbols will mark results of a process.

We now apply this method to the solution of the equ a tion—

$$x^4 + 2x^3 - x^2 - x - 631064798 = 0.$$

It will be found that a root lies between 100 and 200.

1	2	−1	−1	631064798(158
...	100	10200	1019900	101989900
	102	10199	1019899	529074898:
	100	20200	3039900	410987450
	202	30399	4059799:	118087448;
	100	30200	4159950	118087448
	302	60599:	8219749	0
	100	22600	5414950	
	402:	83199	13634699;

	50			
	602;			
...	8			
	610			

Assuming 100 as a first approximation, we find that $x^4 + 402x^3 + 60599x^2 + 4059799x - 529074898 = 0$ is an equation having roots less by 100 than those of the given equation. And 529074898 contains 4059799 upwards of 130 times; but if any number of tens greater than 50 be taken, the accumulations of the next involution will give more than 5290, &c., as must be found by trial. Repeating the process, we find that $x^4 + 602x^3 + 135899x^2 + 13634699x - 118087448 = 0$ is an equation all whose roots are less by 50 than those of the last. We can now depend upon 118087448 divided by 13634699 giving one figure of the root, and the quotient is between 8 and 9. Assuming 8, the first step of the third process shows that 8 is a root of the last equation, and 58 of the preceding, and 158 of the given equation.

We now give an example in which approximation is carried on. Let the equation be $x^3 - 6x^2 + 7x + 4 = 0$, of which one root lies between 2 and 3. The first working column is abbreviated.

		−4·485316‖	2

The root of this equation is found to be 2·414213562, as follows. Beginning with the multiplier 2, one set of involutions brings us to the figures followed by colons, and $x^3 + 0x^2 - 5x + 2 = 0$ is an equation on which the process is to be repeated. Dividing -2 by -5 we find that ·4 is most probably the next figure, which is verified in the next trial, since the result of involution, 1·936, is less than 2. We proceed in this way until 2·4142, containing half the number of figures wanted, is found, and this being a, we have found $-0·000060831$ for $-\phi a$, and $-4·485316$ for $\phi' a$. The first divided by the second may be depended upon for doubling the number of figures, as commonly practised in the extraction of the square root. [APPROXIMATION.] The figures 13562 are found by a contracted division shown in the example.

But it is more convenient to avoid decimals in the process, which may be done as follows 1. If there be decimals in the coefficients of the equation, annex ciphers to every place in such manner that the number of decimals in the several places may be in increasing arithmetical progression. Then strike out the decimal points entirely, and proceed as with whole numbers, remembering that the root thus obtained will be 10 times too great if the progression increase by units, 100 times too great if it increase by twos, and so on. Thus $1·81x^3 - ·6x^2 + 33x + 18·4$ should be changed into $1·81x^3 - ·600x^2 + 33·0000x + 18·40000$, and $181x^3 - 600x^2 + 330000x + 1840000$ will give ten times the required root. 2. When all the whole figures of the root have been obtained, and the decimal part is about to enter the calculation, before attempting to obtain the first decimal figure annex a cipher to the first working column on the left, two ciphers to the second, and so on to the end. Then proceed with the new figure as if it were a whole number, and make a new involution. When this is finished annex ciphers again as before. One additional advantage will be that the ciphers will serve to mark the places of completion of the individual involutions. If in any case ϕa should not contain $\phi' a$, place a cipher in the root, annex ciphers again, and then proceed. In some of the older algebraists, Oughtred for instance, the several vertical lines of figures are kept in their places by a set of ruled columns, the use of which is difficult. Mr. Horner has a similar contrivance; but the employment of ciphers removes all the difficulty, as in common division and the extraction of the square root. See the last example in this article. The method might easily be extended to the whole part of the root.

The following is an instance of the method:—

$$x^4 + x^3 - x^2 - 2x - 2 = 0.$$

Many of the preceding figures are useless, but we have judged it best to present the whole process. The best method of abbreviation is to fix a point of the process from and after which the number of figures in the last column is not to increase, striking off at every step one figure from the last column but one, two from the last but two, and so on. The consequence will be that the several columns on the right will disappear one after the other; the process will be legitimately reduced to termination with a contracted division, independently of the theorem cited; and the result will be true to the last place. The effect of this will be, that as soon as the remaining part of the root is too small for its highest power to show itself in the process, an equation of the $(n-1)$th degree takes the place of the nth, and so on, until there remains only an equation of the first degree, and the approximation then proceeds by the Newtonian method. All this was pointed out by Mr. Horner, whose view of his own method was very complete, in everything but historical information. Had he given in his paper an example from Oughtred, also worked by his own method, pointing out the difference of the two, we feel sure that the question about the right to the invention never would have been discussed.

Taking up the preceding example at the point with which we left off (neglecting the division), and following the process, we have

```

The answer 1·414213562373 is correct to the last place inclusive. (The contracted division follows the thick line.) The rule by which to judge of the extent to which the full process should be continued is as follows: Carry it on until the last column but one has at least two more figures than the number of root figures *remaining* to be found.

Such is the method which must place its author among those valuable inventors who find out simple adaptations which have been overlooked by their predecessors. It is not a little remarkable that this, the most important facilitation which the solution of numerical equations has received since the time of Vieta, and which is, *when known*, a very obvious extension of the extraction of roots, should have only preceded by a few years the most important addition to the method of ascertaining the number of roots which has been made since Des Cartes, and which is also, when known, an equally simple result of the process of finding the highest common factor of two algebraical expressions. [STURM'S THEOREM.]

Two of the most remarkable applications of this method are, the solution of equations of the second degree, which is made as simple as the extraction of the square root, and the extraction of the cube root, which is reduced from an impracticably complicated process to one of perfectly easy performance.

As an example of the first, required the solution of

$$2x^2 + x = 2.$$

Since the root is less than unity, the preparation for decimals is made at the outset.

or $x = ·78077643$, which is correct with the exception of the last place. The extraction of the square root, say of 10, is done by solving the equation $x^2 + 0x = 10$; but it will be found that the solution of any equation of the form $x^2 + ax = b$ may be performed by the same rule as the extraction of the square root. We shall show this, beginning with Horner's rule, and changing to the other after a few steps. Let the equation be $x^2 + 2x = 10$.

In the extraction of roots the method of pointing and bringing down the periods as they are wanted may be followed. The following is the process for the extraction of the cube root of 205692449327; it being remembered that the question is the solution of an equation of the form $x^3 + 0x^2 + 0x = a$.

```

The opposite process is the extraction of the cube root of 1·808, and will serve as an example of the complete process, omitting only the first column, which, with the exception of the unit at the head, is blank. And this is also the type of the solution of any cubic equation whatsoever; the only difference being that the heads of the first and second working columns are ciphers in the extraction of the simple root, and significant in all other cases.

The preparation for decimals makes the answer ten times too great; so that the cube root of 1·808 is 1·218...002, of which only the last figure 2 cannot be depended upon. The preceding contains every figure which need be written down, all the connecting operations being those which are usually performed mentally, and one only is required for each figure. We do not think that any attempt to shorten the work, by leaving out the recurring figures, or employing double mental operations, would save time; and it would certainly very much augment the liability to error. The vertical lines in the example show that part of the operation in which the contraction takes place, and the point at which the contraction becomes simple contracted division is marked by a thick horizontal line. To enable the beginner to examine the process we have placed a letter in every line of the first working column, by which the parts of the second column which are connected with it may be traced; while a letter doubled in the second column shows a multiplicand, the product of which by the root figure is found as marked in the third column. The letters under the last line of the first column mark the figures cut off in the several contractions, and their results in the other columns are traced in the same way: the same for the letters under the second column.

One simplification might be made after the learner has practised a number of examples conducted as above. In the second working column certain lines, namely, the second *b*, the second *e*, the second *h*, &c., are not used except to be added to the next line. Hence each of the lines on which a letter is doubled might be formed by adding the first, third, and fourth preceding lines, and the effect would be to omit some of the lines and some of the most simple additions. The second column, beginning from *pp* inclusive, as a specimen, and changing the line in which ciphers are annexed (and the ciphers should always be annexed to mark the step) would be

```

```

But considering that the process is one which no person will very often perform, we doubt whether to recommend even this abridgment. All such simplifications tend to make the computer lose sight of the uniformity of method which runs through the whole; and we have always found them, in rules which only occur now and then, afford greater assistance in forgetting the method than in abbreviating it.

On evolution of algebraical quantities we do not think it necessary to speak, since either the binomial theorem [BINOMIAL THEOREM], or some other method of development, is employed with more advantage than the usual modification of the arithmetical process. We have also omitted the process of division, the most simple of all evolutions, since its connection with the preceding is sufficiently obvious.

There is however a process of an evolutionary character which we take this opportunity of suggesting, and of which any one moderately conversant with algebra will easily arrive at the demonstration. In finding the highest common divisor of two algebraical integral expressions, and also in the process of Sturm's Theorem, it is required to divide one ex-

pression, P, by another, Q, not for the sake of finding the quotient, but the remainder; and this remainder, cleared of all numerical factors and of fractions, is preferable. The following rule will render the application of Sturm's Theorem much more easy.

Question:—Two expressions, P and Q, being given, of which P is lower than Q, required the remainder of Q divided by P, cleared of fractions and of positive numerical factors. To take an example with us, let

$$P = 2x^3 - x - 4$$
$$Q = 4x^5 - 3x^4 + 2x^2 - x + 1.$$

1. Add 1 to the difference of the degrees $(5 - 3 = 2,\ 2 + 1 = 3)$: this is the number of operations to be expected. In this case it is three.

2. Write down in two lines the coefficients of the divisor and dividend, including the coefficient 0 for every missing term, but change the sign of every coefficient in the divisor, *except the first*. Clear both expressions of all whole factors; and if the two leading coefficients (2 and 4) have a common factor, divide by this factor before writing them down. Write ciphers in all blank places.

(P)	1	0	1	4	0	0
(Q)	2	−3	0	2	−1	1

2. Take the first vertical pair, and every other in succession, and make cross multiplication and addition: thus $\begin{matrix} a & . & . & c \\ b & . & . & d \end{matrix}$ gives $ad + bc$. Put the first result in the first column, the second in the second, and so on.

(1) −3 2 10 −1 1

3. Repeat this process with the first line, and the result just obtained, and again with the result, making each new result out of the first line and the last result, and so on till the number of operations ascertained in the first clause of the rule has been performed. But if the leading term of the first line have been divided, multiply it again after the result, unless the first term of the result be also divisible by the same factor.

4. But if ever the first column of a result should turn out a cipher, throw it away, and bring forward the next column, and so on: making every step stand in the next higher place: and if the two first columns of any result should be ciphers, throw them away, and bring forward the third, and so on. And for every cipher thus thrown away diminish by one the number of operations required in the first clause.

5. If any horizontal line thus obtained have a factor in all its terms, divide by that factor before proceeding further: and if the leading term of any new result have a factor in common with the leading term of the first line, divide both before proceeding.

The table of results now is as follows, in which the various changes of the leading terms are shown by putting them down as they occur, and putting a bar over them as they disappear and are replaced by others. In practice the pen may be drawn through the figure which is dismissed.

(P)	$\bar{2}$, $\bar{1}$, $\bar{2}$, 1	0	1	4	0	0
(Q)	$\bar{4}$, 2	−3	0	2	−1	1
(1)	−$\bar{3}$	2	10	−1	1	
(2)	$\bar{4}$, 2	17	−14	2		
(3)	17	−12	10			

$17x^2 - 12x + 10$ Answer

6. When the last result has been obtained make an algebraical expression one degree lower than the divisor, the coefficients of which are the numbers in the last result, with their signs.

The real remainder in the preceding example is $8\frac{1}{2}x^2 - 6x + 5$.

Let the next example be

$$P = 4x^3 - 6x^2 + x + 1$$
$$Q = 2x^6 - 3x^5 + 2x^4 + x^3 - 3x^2 - 3x + 4.$$

Here the number of operations should be four; but it is reduced by the circumstance mentioned in the fourth clause of the rule.

(P)	$\bar{4}$, $\bar{2}$, $\bar{4}$, 2	6	−1	−1	0	0	0
(Q)	$\bar{2}$, 1	−3	2	1	−3	−3	4
(1)	$\bar{0}$,* 3	1	−6	−6	8		
(2)	$\overline{22}$, 11	−27	−27	32			
(3)	12	−65	53				

$12x^2 - 65x + 53$ Answer.

* Then bring forward the next column.

The method of proof of the several processes, as their results arise, is as follows: Make an additional proof column, in which place the sums of the numbers in each line, taken with their signs; making these sums vary with the variation of the leading factors: thus

			Proof.
a	b	c	A
p	q	r	P
$aq + bp$	$ar + cp$	. . . . . .	Z

Here A is $a + b + c + \ldots$; B is $p + q + r + \ldots$; and Z is $aq + bp + ar + cp + \ldots$. If then the process be correctly done, an extension of it to the proof column gives aP + Ap, which ought to exceed Z by $2\,ap$.

We shall conclude this article with the process which will be applied hereafter. [STURM'S THEOREM.] The object is to proceed as in finding the greatest common divisor of P and Q, changing the sign of every remainder before using it.

$$P = 4x^3 - 9x^2 - 4x + 1$$
$$Q = x^4 - 3x^3 - 2x^2 + x - 3.$$

					Proof column.
4	9	4	−1	0	16
1	−3	−2	1	−3	−6
−3	−4	3	−12		−16
−43	0	−45			−88
43	0	−45	0		−2
4	−9	−4	1		−8
−387	−352	43			−696
−15136	19264				4128
15136	19264				34400
43	0	45			

The remainders therefore, with the signs changed as directed, are $43x^2 + 45$, $15136x - 19264$, and the last is a negative whole number. The following is the first instance of the use of the proof column:—

$$1 \times 16 + 4 \times (-6) - (-16) = 8 = 2(4 \times 1)$$

IODINE, a non-metallic elementary or simple solid body, which was discovered by M. Courtois, of Paris, in 1812. Its peculiar properties were however first ascertained by Gay-Lussac and Davy. Iodine exists in the water of the ocean and mineral springs, probably combined with sodium, in marine molluscous animals and sea-weeds; it has also been met with in combination with silver. Iodine is principally obtained from *kelp*, or sea-weed which has been burnt for the purpose of obtaining alkali from it. When the alkaline and other salts have been separated, the residual solution is treated with sulphuric acid and binoxide of manganese, by which the iodine is set free, the decomposition being analogous to that by which chlorine is obtained by the same agency from common salt.

Iodine is a soft opaque solid, of a bluish-black colour and metallic lustre. The primary form of the crystal is a right rhombic prism, and the crystals are usually flat. According to Gay-Lussac, its specific gravity is 4·948. When moderately heated, it rises in vapour of a violet colour, and hence its name from the Greek. On cooling, it again crystallizes unchanged, nor is it decomposed or altered by being subjected to very high temperatures, and it has resisted all attempts to decompose it. Iodine has a strong disagreeable odour and taste resembling those of bromine and chlorine; it stains the skin of a brownish colour, but not permanently. It is readily dissolved by alcohol; the solution is of a reddish-brown colour, but so little is taken up by water that a pound of water will not dissolve more than a grain of it. It is very poisonous. Its characteristic property is that of giving an intense blue colour when added to a solution of starch. It unites with metals to form compounds, which are termed *iodides*, and, like chorine and bromine, it forms acids both with hydrogen and oxygen.

Oxygen and Iodine combine to form probably four compounds; the first is *oxide of iodine*. When the vapour of iodine and oxygen gas are mixed at rather a high temperature, the violet tint of the iodine disappears, and a yellow soft substance is formed, which is regarded by Sementini as oxide of iodine; if this be subjected to the action of more oxygen gas, it is converted into a yellow liquid, which the same chemist supposes to be iodous acid; but the composition and properties of these compounds have not been accurately determined.

Iodic Acid.—This compound was first obtained by Davy by the action of iodine upon what he called euchlorine gas. A better process has however been proposed by Mr. Connell, which consists in heating the iodine in the strongest nitric acid. For this purpose the acid should be introduced with about a fifth of its weight of iodine into a tube about an inch wide and 15 inches long, and sealed at one end, and these materials are to be kept boiling for 12 hours; the iodine which rises and condenses on the sides of the tube is to be returned to the acid either by a glass tube or by agitation; when the iodine disappears, the excess of nitric acid is to be got rid of by evaporation. Iodic acid is a white semitransparent solid substance, which is inodorous, but has an astringent sour taste. It is so dense as to sink in sulphuric acid, and it deliquesces in a moist atmosphere. It is very soluble in water; the solution reddens vegetable blue colours; it detonates when mixed and heated with charcoal, sugar, and sulphur. It combines with metallic oxides to form salts, which are termed *iodates*, and these, like the chlorates, yield oxygen when heated; and an iodide remains.

Iodic acid is composed of

Five equivalents of oxygen 8 × 5 =	40
One equivalent of iodine	126
Equivalent	166

Oxiodic or Periodic Acid.—When chlorine is added to saturation to a solution of iodate of soda with excess of the alkali and concentrated by evaporation, a sparingly soluble white salt is obtained, which is *oxiodate of soda*: when this is dissolved in dilute nitric acid and mixed with nitrate of silver, a yellow precipitate falls, which, dissolved in hot nitric acid and evaporated, yields orange-coloured crystals of oxiodate of silver; these are decomposed by cold water, and an aqueous solution of pure oxiodic acid is formed; this by cautious evaporation yields hydrated crystals, and these, when heated to 212°, are resolved into oxygen and iodic acid. It consists of

Seven equivalents of oxygen 8 × 7 =	56
One equivalent of iodine	126
Equivalent	182

Azote and Iodine form iodide of azote. This compound cannot be obtained by direct action, on account of the weakness of the affinity existing between its elements. It is prepared by putting iodine into an aqueous solution of ammonia, which being decomposed, its hydrogen forms hydriodic acid with one portion of the iodine, whilst the azote combining with another portion of it, the result is iodide, or, correctly speaking, teriodide of azote, which remains insoluble in the state of a dark brown powder. This compound is very explosive, especially when dry: the best method of exhibiting its power is that of allowing it to dry in small portions on bibulous paper, and then simply letting it fall on the ground or merely touching it, it detonates with a sharp noise, heat and light being emitted, and the vapour of iodine and azotic gas are evolved. It is not dangerously explosive. It i composed of

One equivalent of azote . .	14
Three equivalents of iodine 126 × 3 =	378
Equivalent	392

Hydrogen and Iodine form hydriodic acid, which may be prepared by the direct combination of its elements. When a mixture of iodine in vapour and hydrogen gas is passed through a red-hot porcelain tube, they combine to form this acid. It is however much more conveniently formed by heating in a retort one part of phosphorus and about 12 parts of iodine moistened with water; by the mutual action of these substances the water is decomposed, its oxygen combines with the phosphorus, forming phosphoric acid, while the hydrogen unites with the iodine to form hydriodic acid, which passes over in the state of a colourless gas. This acid has a sour taste, reddens vegetable blues, and when mixed with atmospheric air forms dense white fumes with its moisture: its odour resembles that of hydrochloric acid gas. It is soluble in water. The salts which it forms are termed hydriodates: but when it is acted upon by metals, hydrogen is evolved, and when by metallic oxides, water is formed, and in both cases iodides are the result.

It is decomposed by oxygen when they are heated together; water is formed, and iodine evolved. It is also immediately decomposed by chlorine, which unites with its hydrogen to form hydrochloric acid, and iodine is set free. It is composed of

One equivalent of hydrogen	1
One equivalent of iodine	126
Equivalent	127

One volume of it consists of half a volume of hydrogen gas and half a volume of the vapour of iodine.

Chlorine and Iodine appear to form three chlorides. The protochloride may be obtained by passing a current of chlorine gas into water in which chlorine is suspended; a deep reddish solution is formed, which yields irritating fumes possessing the smell of both the elements; it first reddens and then bleaches litmus paper. The terchloride may be formed by repeatedly distilling the protochloride. The perchloride when decomposed by water gives rise to hydrochloric and iodic acids. The opinions of chemists with respect to these compounds are yet somewhat at variance.

Sulphur and Iodine is formed by heating gently a mixture of 1 part of sulphur and 4 parts of iodine. The product is of a dark colour, and has a radiated structure; it is easily decomposed by heat.

Iodine and Phosphorus combine readily without the application of heat; and so much heat is evolved by their action that the phosphorus takes fire if the experiment be made in the open air; but in close vessels no light appears. The composition of iodides of phosphorus is rather uncertain; that which is probably a protiodide is formed with one part of phosphorus and seven or eight parts of iodine; it has an orange colour, fuses at 212°, and when heated sublimes without changing; it is decomposed by and decomposes water, forming with its elements hydriodic and phosphorous acids, while phosphorus is set free. It is probably composed of

One equivalent of iodine	126
One equivalent of phosphorus	16
Equivalent	142

The sesquiodide is formed by the action of 1 part of phosphorus and 12 parts of iodine. It is a dark grey crystalline mass, which fuses at 84°, and with water yields hydriodic and phosphorous acids. It is composed of

One and a half equivalent of iodine	189
One equivalent of phosphorus	16
Equivalent	205

The periodide is prepared with 1 part of phosphorus and 20 of iodine; it is a black compound, fusible at 114°. By the action of water it yields hydriodic and phosphoric acids, and hence it is inferred to consist of

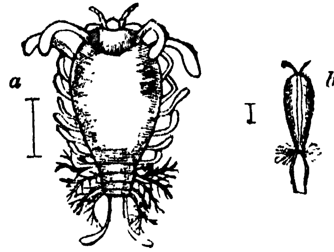
Two and a half equivalents of iodine	315
One equivalent of phosphorus	16
Equivalent	331

Iodine and Carbon unite to form two compounds, but not by direct action. They are not important, and their composition has not been ascertained.

The compounds of iodine and metals are mentioned under each metal.

IODINE, *Medicinal Properties of.* Iodine, though only obtained in an isolated state of late years, has been long employed as the efficient principle of other preparations and therapeutic agents, namely, burnt sponge and certain mineral waters. It is only since it has been procured as a distinct principle that its action has been ascertained with precision. In the present day it is administered rather in some artificial compound than as pure iodine, owing to its very sparing solubility in water. Iodine in substance, however, when applied to the skin, stains it brown, and even the very small quantity which can be dissolved in water is sufficient to cause rubefaction, and in the form of baths produces decided action both on the surface of the body and the general system. When applied to ulcers or any breach of the skin, it occasions heat and a sense of pricking and tingling; it is also absorbed, and may be discovered in the blood and the secretions of the patient. Taken internally, even in small doses, it causes a sense of heat in the mouth and throat; if much diluted by the vehicle in which it is given, and the stomach be healthy, it appears to do little more than increase the digestive powers; but in larger and stronger doses it creates great heat in the region of the stomach, which becomes sensible to pressure, with a feeling of

weight, heartburn, and often nausea and vomiting. In very large doses it acts as an irritant poison. It is not merely an irritant poison when taken in a large dose, but is a slow or accumulative poison, even when taken in medicinal doses for a length of time. It has been generally represented as causing emaciation even to a frightful extent; but though this has occurred in some instances, it does not seem to be frequent, if we except the absorption of certain glands, especially the mammæ of females.



The diseases in which it has been found useful are glandular swellings, especially bronchocele or goître, which rarely resists its action; in some strumous diseases, in chronic rheumatism, and also as an antidote against poisoning with strychnia, brucia, and verataria: but its claims to confidence are not clear in case of such formidable poisons. It is often of use in lessening the injurious effects of mercury and in the treatment of the sequelæ of syphilis. (See Lugol, *On Scrofula.*)

IONA, also known by the names of I-Colm-Kill and Hii or I, is one of the Hebrides, in the district of Mull, and belonging to the shire of Argyle. It is situated on the western side of the Isle of Mull, from which it is separated by a narrow channel called the 'Sound of I.' Its length is three miles, and at its widest part it is about one mile in breadth. The general aspect of the country is rugged and mountainous, and the surface for the most part consists of moor and bog occasionally varied by a patch of green pasture. The village is a miserable collection of huts inhabited by a population of about 450 people. There seems to be no doubt that the island was antiently inhabited by Druids, who were expelled by the Christians about the time that St. Columba came to Britain (A.D. 565), and the inhabitants still point out the spot where this holy man is traditionally said to have been interred. The religious institutions established by the Christians remained unmolested for nearly 200 years; but about the beginning of the ninth century the Danes made a descent upon the island, and, with their accustomed barbarity, put to death the greater part of the monks, forcing the remainder to seek safety in flight. At the dissolution of the monastic institutions the revenues were united to the see of Argyle, and upon the abolition of episcopacy they became the property of the duke. At the present time the island is chiefly interesting on account of its numerous architectural and other antiquities, for a full account of which we must refer the reader to Dr. Macculloch's 'Highlands and Western Isles of Scotland.' The cathedral or abbey church is surmounted by a lofty tower, which is supported by four arches adorned with figures in basso rilievo. The choir is handsome, and the large eastern window is a beautiful specimen of the Gothic style, although its light and elegant workmanship has been much injured by time. In the fore court are two finely cut crosses; one called St. Martin's is formed of a single piece of red granite, 14 feet in length. The cathedral itself is dedicated to St. Mary, and, according to Boethius, was built by Malduinus in the seventh century, but Dr. Macculloch thinks this at least seven centuries too soon.

(*Beauties of Scotland;* Macculloch's *Highlands*, &c.)

IONE, or as it is sometimes written, JONE, a parasitic genus of crustaceans, placed by Desmarest under the *Isopoda*, but by Latreille, who established the subgenus, under the *Amphipoda*. The latter founded his separation on the figure given by Montagu under the denomination of *Oniscus thoracicus* (*Linn. Trans.*, ix. iii., 3, 4); and observes that it presents particular characters which place it at a distance from all the other forms of the order. The body is composed of about fifteen joints, which are only to be distinguished by lateral incisions in the form of teeth. The four antennæ are very short: the external ones, longer than the two others, are only visible when the animal is seen on the back. The two first segments of the body in the female are each provided with two elongated, fleshy, flattened, oar-like cirrhi. The feet are short, hidden under the body, and hooked. The six last segments are furnished with lateral, fleshy, elongated, fasciculated appendages, which are simple in the males, but in the form of oars in the other sex. At the posterior extremity of the body are six other appendages, which are simple and curved, two of them being longer than the others. The abdominal valves are very large, cover all the lower part of the body, and form a species of receptacle for the eggs.

Habits.—This parasite hides itself under the shell of *Callianassa subterranea* [CALLIANASSA], and there forms a tumor on one of its sides. Montagu extracted it, and kept it alive for some days. The females are always accompanied by their males, which are very inferior in size, and fix themselves firmly upon the abdominal appendages of the former by means of their claws. Latreille, whose account we have given, speaks of it as rare, and remarks that in its habits it approaches to *Bopyrus*. [ISOPODA.]

Ione thoracica. *a*, Female; *b*, Male. (Montagu, *Linn. Trans.*)

N.B.—M. Milne Edwards (ed. Lamarck, 1838) remarks, that all the figures referred to are copied from those of Montagu, and are very bad. Montagu states that the crustacean on which these parasites are found is rare, but that, in the few that he had obtained, two or three pairs of the parasites had occurred.

IO'NIA and IONIANS. Ionians is the name of one of the various peoples included in antient history under the general name of Hellenes or Greeks. [ACHÆI; ÆOLIANS; DORIANS.] The origin of the Ionians is involved in great obscurity. The name only occurs in the Iliad once, and in the form 'Iaones' (N. 685); but not many years after the war of Troy, the Ionians appear as settled in Attica, and also in the northern part of the Peloponnesus, along the coast of the Corinthian Gulf. Herodotus (viii. 44) says that the Athenians were originally Pelasgi, but that after Ion, the son of Xuthus, became the leader of the forces of the Athenians, the people got the name of Ionians. It appears probable that the Ionians, like the Æolians, were a conquering tribe from the mountains of Thessaly, and that at an unknown period they migrated southwards and settled in Attica and part of the Peloponnesus, probably mixing with the native Pelasgi. The genealogy of Ion, the reputed son of Xuthus, seems to be a legend under which is veiled the early history of the Ionian occupation of Attica. Euripides, in order to flatter the Athenians, makes Ion the son of Apollo. Whatever may be the historical origin of the Ionian name, Athenians and Ionians came to be considered as one and the same people. [ATHENS.] In the Peloponnesus the Ionians occupied the northern coast of the peninsula, which was then called Ionia, and also Ægialæan Ionia; and the sea which separates Peloponnesus from Southern Italy assumed the name of Ionian Sea, a circumstance which would seem to indicate the extent and prevalence of the Ionian name. This appellation of Ionian Sea was retained among the later Greeks and the Romans, and it is perpetuated to the present day among the Italians. When the Dorians invaded the Peloponnesus, about 1100 years B.C., the Achæi being driven from thence gathered towards the north, and occupied Ionia, which after that time took the name of Achæa. The Ionians of the Peloponnesus emigrated to Attica, whence, being straightened for want of space, and perhaps also harassed by the Dorians, they resolved to seek their fortune beyond the sea, under the guidance of the sons of Codrus, the last king of Athens. This was the great Ionian migration, as it is called. The emigrants consisted of natives of Attica, as well as of Ionian refugees from the Peloponnesus, and a motley band from other parts of Greece (Herod. i. 146). But this migration can perhaps hardly be considered as one single event: there seem to have been many and various migrations of Ionians, some of which were probably anterior to the Dorian conquest. Thus the Ionians established colonies in most of the Cyclades, such as Naxos, Andros, Paros, and Delos, and also in Eubœa. The emigrants who proceeded to the coast of Asia, under their leader Neleus, took Miletus, which was then inhabited by the Carians. Miletus seems to have fallen to the share of the Athenian Ionians, who, according to the frequent custom of those times, massacred all the men, and kept the women for themselves. They also colonized Myus and Priene, near the banks of the Mæander. Another party of Ionians under Androclus took possession of Ephesus, and drove away the Leleges and

Carian inhabitants. [EPHESUS.] They likewise occupied Lebedos and Colophon, the latter of which towns was inhabited by Cretans, who appear to have amalgamated with the Ionian colonists. Further north Teos, which had been built by the Æolians, received also an Ionian colony, as well as Erythræ on the coast facing the island of Chios. On the north coast of the same peninsula Clazomenæ was founded afterwards by a colony from Colophon, and later still Phocæa was colonized by adventurers from Phocis and Ionians from Attica on a territory north of the Hermus, which belonged originally to the Cumæans of Æolia. The above towns, with the two islands of Chios and Samos, which the Ionians likewise colonized, formed the confederation of the twelve cities of Ionia. Smyrna being seized by Colophonian exiles (according to Herodotus), was in course of time added to the confederation. Other colonies from the twelve cities were built along the coast, such as Geræ, Myonnesus, Claros, &c.

This confederation appears to have been mainly united by a common religious worship and the celebration of a periodical festival; and it seems that the deputies of the several states only met in times of great difficulty. The place of assembly was the Panionium, at the foot of Mount Mycale, where a temple, built on neutral ground, was dedicated to Poseidon. In the old Ionia (afterwards called Achæa), Poseidon was also the national deity, and his temple continued at Helice till that city was destroyed by the great earthquake. That the settlers in Asia should retain their national worship is a circumstance perfectly in accordance with the history of colonization, and confirmatory, if confirmation were wanted, of the European origin of the Ionians of Asia. We have no materials for a history of these cities of Ionia as a political community, and no reason for supposing that their political union came near the exact notion of a federation, as some have conjectured.

Asiatic Ionia extended from the Cumæan gulf on the north to Mount Grius and the gulf Basilicus south of Miletus, a length of not more than 100 miles in a straight line, but with a coast three times that length, owing to the many sinuosities and the form of the large Chersonesus opposite Chios. The Ionian territory did not extend inland above 40 miles from the coast as far as Mounts Sipylus and Tmolus. It bordered on the north upon the territory of Pergamus, Cumæ, and other Æolian cities which had been colonized several generations before the Ionian immigration, and on the south upon Caria, where the Dorian colonies formed, some time later, a small confederation. The principal rivers of Ionia were the Hermus, the Caystrus, and the Mæander, all three flowing from the interior with a western course into the Ægean. [ANATOLIA.]

The Asiatic Ionians early attained a high degree of commercial and maritime prosperity. Miletus alone is said to have founded 75 towns or colonies. They became wealthy, refined, and luxurious. The remains of their monuments prove their taste for the arts, and their temples and public buildings rivalled those of European Greece. The literature of Greece may be said to have originated on the coast of Asia Minor. The historian Hecatæus was a native of Miletus; Thales, one of the earliest philosophers, was from the same country. Anacreon was a native of Teos; and Herodotus, though a Dorian, adopted, in his History, the language of his Ionian neighbours.

The Lydian kings, whose capital was at Sardis, made war against the Ionian states, who only obtained peace and preserved a kind of independence by paying tribute, but they were finally subdued by Crœsus. They remained faithful to the Lydians, when attacked by Cyrus (B.C. 546), in consequence of which, that monarch having subdued the Lydians, sent his general Harpagus to reduce Ionia. Harpagus took and destroyed Phocæa, and the surviving inhabitants fled by sea, and founded Massilia (Marseille) on the coast of Gaul. About the same time many of the Teians left their country and founded Abdera in Thrace. Priene was taken by Harpagus, and the inhabitants were sold as slaves. Miletus and the other cities obtained peace on the same conditions as they had accepted under the kings of Lydia. In almost every town there were two parties, aristocratic and democratic, and the Persian kings or their satraps generally favoured the former, and thus it happened that most of the Greek cities in Asia came to be ruled by tyrants, or individuals who possessed the sovereign power. Aristagoras, who was deputy tyrant of Miletus in the time of the first Darius, having quarrelled with the Persian satrap, urged his fellow-countrymen the Ionians to revolt, to expel their tyrants, and to establish democracy. He set the example by resigning his power. Hecatæus, who saw the danger of rousing the formidable power of Persia, in vain opposed this rash measure. Aristagoras proceeded to Athens, and obtained the assistance of a fleet. The Athenians and Ionians united marched to Sardis, and plundered and burnt the city, but the Persians coming in great force, the confederates were defeated, and the Athenians withdrew from the contest. The Ionian fleet was strong at sea, but could not prevent the satrap Artaphernes from attacking and taking their cities by land. Clazomenæ was taken and destroyed, but the inhabitants some time after built a new town upon an island near the coast. Miletus was captured after a gallant defence, most of the inhabitants were killed, and the rest were transplanted into Persia, where Darius gave them lands and a settlement. The territory of Miletus was given up to Persian or Lydian colonists. Thus ended, about 494 B.C., the Ionian revolt, which lasted six years. Miletus however seems to have recovered from its ruin after a time, and the victories of the Greeks over Xerxes had the effect of restoring the fugitives to their respective cities.

After the battle of Mycale (B.C. 479), and the victories of Cimon, the Greeks became absolute masters of the sea, and the Persians did not venture near the coast. The Athenians, who had taken the lead in the close of the Persian war, now obtained a kind of supremacy on the eastern coast of the Ægean, and the Ionian cities acknowledged Athens as their leader and the arbiter of their disputes. At the close and after the conclusion (B.C. 404) of the Peloponnesian war, the Lacedæmonians gained the ascendency, and the towns of Asia changed protectors. Accordingly we find Agesilaus reconciling their intestine feuds, and professing, as the object of his expedition into Asia, to secure their independence. But by the peace of Antalcidas, 387 B.C., the towns on the continent of Asia were given up to the king of Persia, who however does not appear to have treated them harshly, for many of them were in a prosperous state at the time of Alexander's expedition. After the battle of the Granicus the democratic party at Ephesus and other towns resumed the upper hand, and Alexander gave them his countenance, at the same time forbidding them strictly from offering any further violence to the vanquished aristocracy. Miletus alone did not submit; it sent proposals however to Alexander, offering to remain neutral, but the conqueror sternly repulsed the proposal: the town was taken by storm, and most of the inhabitants put to the sword. It does not seem to have ever after completely recovered from that blow; and the gradual deposits of the Mæander, which have totally changed the appearance of the coast, contributed to its depression. Miletus, once a seaport town, is now eight miles from the sea, and the island of Lade, which stood at the entrance of its harbour, is become part of the mainland. Miletus however was still a town of some consequence under the Romans, and under the Byzantine emperors, till the twelfth century, when it was ravaged by the Turks. There are now only a few huts amidst its ruins inhabited by some Turkish families, but the place retains the pompous name of Palatska, or 'the palaces.' Chandler found remains of a vast theatre, and also of the famous temple of Apollo Didymæus in its neighbourhood, with several of the columns still standing. Under the Roman empire several of the other cities of Ionia still maintained the rank of wealthy cities, such as Smyrna and Ephesus. The best account of the actual state of the remains of the Ionian cities is in Chandler's *Travels in Asia Minor*, and the *Ionian Antiquities*, published by the Dilettanti Society, 2 vols. fol., with handsome plates. (See also Leake's *Map of Asia Minor;* Macfarlane's *Constantinople in* 1828; and Chishull's *Asiatic Antiquities;* Herodotus, i. 141-151; Strabo, lib. xiv.; Pausanias, vii. 1-5.)

Coin of Clazomenæ.

British Museum. Actual Size. Gold. Weight, 88 grains.

IONIAN ISLANDS is the name given to the Seven islands of Corfu, Cephalonia, Zante, Santa Maura, Ithaca,

Paxo, and Cerigo, which are scattered along the coast of Epirus and of the Peloponnesus. The name is probably derived from their being situated in that part of the Mediterranean which stretches between Greece and Calabria, and which from antient times has received the name of the Ionian Sea. [IONIA.] These islands are described under the several heads of CEPHALONIA, CORFU, ITHACA, ZANTE, &c. Under the head CORFU an account is given of the present constitution and administration of the republic of the United Ionian Islands under the protection of Great Britain. The following is a general view of the population, extent, produce, trade, and education of these islands.

Population.—A statement of the area, population, &c. of each island in 1834:—

ISLANDS.	Area in Square Miles.	Total Population.		Aliens and Resident Strangers (included in the Total Population).	Population to the Square Mile.	Persons employed in			Births.	Marriages.	Deaths.
		Males.	Females.			Agriculture.	Manufactures.	Commerce.			
Corfu	227	32,909	27,981	9,040	264	15,077	1621	1443	2507	597	1672
Cephalonia . . .	348	30,875	25,951	348	163	12,689	1471	835	1567	286	799
Zante	156	18,991	16,632	1,217	228	7,672	1947	421	974	284	1181
Santa Maura . .	180	9,592	8,258	195	100	2,158	132	470	525	110	811
Ithaca	44	4,902	4,664	108	217	1,407	196	931	246	52	128
Cerigo	116	4,091	4,488	37	74	1,522	261	198	248	61	118
Paxo	26	2,560	2,501	223	195	217	198	65	175	34	109
Total . .	1097	103,920	90,475	11,168	177	41,012	5829	4363	6242	1424	4818

Produce, Exports, Imports, &c.—The principal articles of export from the islands are olive oil and currants. Oil is chiefly the produce of Corfu, but in all the islands the olive-tree is more or less cultivated. Cephalonia and Zante are the only islands in which currants are grown, with the exception of Ithaca and Santa Maura, in which a few acres are employed in that cultivation.

ISLANDS.	CROPS.—Number of Acres of Land under each Kind of Crop.											
	Wheat.	Indian Corn, Calambocchio, Barley, and Wheat.	Oats.	Currants	Olives.	Vines.	Cotton.	Flax.	Pulse.	Pasture.	Total in Crop.	Total Uncultivated.
Corfu	4,005	13,508	2,963	..	75,700	13,900	69	843	1,020	17,422	112,008	33,272
Cephalonia . .	682	6,963	637	6,212	4,323	12,232	473	351	1,033	610	32,934	189,786
Zante	7,182	966	492	6,410	16,766	13,600	327	134	64	1,474	45,971	53,869
Santa Maura . .	1,234	3,249	386	8	8,143	4,127	111	75	212	5,494	17,539	97,661
Ithaca	49	263	5	190	212	756	1	97	38	1,626	1,611	3,286
Cerigo	453	8,466	..	..	513	1,365	54	109	1,595	5,285	12,555	61,685
Paxo	..	..	..	..	11,000	406	..	..	..	..	11,406	5,234
Total . .	13,605	33,415	4,475	12,880	116,657	46,386	1,035	1,609	3,962	31,941	234,021	444,793

Total Produce.—Wheat, 234,727 bushels; Indian corn, &c., 177,065 bushels; oats, 23,944 bushels; currants, 15,071,400 lbs.; oil, 253,923 barrels; wine, 306,822 barrels; cotton, 45,145 lbs.; flax, 94,522 lbs.; pulse, 19,826 bushels; salt, 114,193 lbs.

The exports from the Ionian Islands in 1833 amounted to 250,669*l.*, and consisted principally of olive oil, currants, wine and spirits, soap, and some other articles of less importance.

The imports into the Ionian Islands in 1834 amounted to 563,611*l.*, and consisted of sugar, coffee, cotton and woollen goods, earthenware, hardware, timber, wheat, rice, cheese, cattle, sheep, and a variety of other articles.

Education.—The following is the number of schools, &c., as they existed in 1834:—

ISLANDS.	Public or Free Schools.							Private Schools.			
	Number.	Number of Scholars			Mode of Instruction.	Mode of Support.	Total Expenses.	Number	Number of Scholars.		
		Males.	Females	Total.					Males.	Females	Total
Corfu . . .	4	294	..	294	Classical and Lancasterian.	Wholly by the Government.	£3,261	67	1,955	353	2,308
Cephalonia . .	12	445	59	504			867	73	1,207	..	1,207

Paxo . . .	5	122	49	171			258	..	..	..	..
Total .	36	1789	117	1906			6,172	206	4,583	826	5,409

At Corfu there is a university, and also an ecclesiastical seminary for the education of young men intended for the priesthood of the Greek church. Each of the islands also has a school, entitled 'Secondary,' in which the scholars are instructed in the Greek and Latin classics, in the modern Greek, English, and Italian languages, and in arithmetic and elementary mathematics. In the chief town of each island there is a central school, on the mutual instruction plan, for teaching reading, writing, and arithmetic.

Besides these schools, conducted entirely at the public expense, there are in each island district schools on the same plan as the central schools, where similar instruction is given, and the expense is defrayed by the parents of the children. The terms per scholar vary greatly, and the payment is frequently made in kind. Government also contributes to the establishment of these schools by furnishing books, slates, benches, &c., and, where no suitable church exists for the purpose, by providing a school-house.

The district and village schools are under the immediate superintendence of the head master of the central school in each island, and there is an inspector-general of all these schools. The whole of the establishment for education is under the general direction of the commission for public instruction.

The only coinage of the states is a copper currency of farthings to the amount of 10,000*l.* The general circulating medium consists of Spanish dollars. Some British silver coin has also been put into circulation, but the greater part has been withdrawn for remittances to Malta and to England.

The Troy pound of 5760 grains is the standard weight: 24 of these grains make 1 calco; 20 calchi 1 ounce; and 12 ounces 1 libbra sottile, or pound light weight, equal to 1 lb. Troy. The libbra grossa, or great pound, contains 7000 grains, and is therefore equivalent to the pound avoirdupois; 100 lbs. (libbra grossa) are called a talento. The English imperial standard yard is the standard linear measure, with the divisions into 3 feet and 36 inches: 5½ yards are 1 camaco; 220 yards 1 stadio; and 1760 yards 1 mile. The imperial gallon is the measure of capacity: 1 gallon is equal to 8 dicotoli. An Ionian barrel contains 16 gallons, or 128 dicotoli.

IONIAN SCHOOL comprises several of the earliest philosophers of Greece, whose speculations were predominantly of a physiological character, and who, with one or two exceptions, were natives of the Ionian colonies in Asia Minor. From this purely external circumstance the school has derived its name, and its members have been brought into an unbroken connexion of masters and disciples by the learned labours of the later Greeks, who strove to give to the first development of philosophy the same orderly transmission of doctrine which prevailed in the later schools. Accordingly Anaximander is made the scholar of Thales and the teacher of Anaximenes, who had two disciples, Diogenes of Apollonia in Crete, and Anaxagoras, whose disciple was Archelaus of Athens, or Miletus, in whom the school closes. Now, not to mention that this purely artificial arrangement omits Heraclitus, the chief of the Ionians, it is also open to great difficulties both of doctrine and chronology. As regards the latter however, we shall only advert to the general difficulty, that between six and seven generations (212 years) are occupied by the lives of Thales, Anaximander, Anaximenes, and Anaxagoras. The incongruity of the received arrangements appears at once on the slightest consideration of the doctrinal systems of the philosophers of this school. Agreeing in the hypothesis of a primeval state of things, they differed widely in the mode in which they accounted for the deduction of existing phenomena out of the primal substance. One theory endued the universe with life, and considered the orderly procession of all things to be a spontaneous development of a pre-existent germ of life. A second accounted for all apparent alteration in the form and qualities of natural bodies by certain changes in the outward relations of space, and proceeded on the supposition of certain permanent material elements which change place in obedience to motion, either originally inherent in or extrinsically impressed on the mass. The latter is the mechanical, the former the dynamical theory of nature. Of the dynamical theorists, Thales first of all taught that all things are pregnant with life; that the seed or germ of vitality, which is in all things, is water, because all seed is moist and humid. Of this potentially living entity Anaximenes advanced a still worthier representation, and taught that the primal substance is infinite and sensuously imperceptible. This principle is analogous to the animal soul, and as the animal soul governs the body, so the universal soul rules and embraces all things. Diogenes made a still farther advance, and maintained that the harmony and design of the mundane fabric suggest the unity and intelligence of its first principle. This principle however he considered as simply physical, and only distinguished from natural phenomena in this, that while it is infinite, as the principle of all, they are finite. Still bolder was the flight of Heraclitus, who taught that the world is an everliving being, a rational fire, whose vitality involves a tendency to contraries, and is ever passing from want to satiety.

The mechanical theory is first opened by Anaximander, who flourished not long after Thales, who conceived the ground both of production and motion to be an eternal substance, which he called the infinite, and wherein the immutable elements were indistinguishably combined. Out of this chaos certain primary contraries, as he conceived them, cold and warm, earth and heaven, were first evolved, and in the course of certain separations and combinations alternately proceeding, more perfect forms are spontaneously developed, to be ultimately resolved into the homogeneous primary. After a long interval of a century Anaxagoras revived the mechanical physiology, and distinctly advanced the principle on which it rests, that nothing is changeable, but that the nature of every thing is permanent. Seizing the contrariety of the moving and the moved, which the mechanical theory is so well calculated to exhibit, he defined the latter to be extended antitypous bulk, inert body, infinitely multiple both in qualities and parts. The moving principle, on the contrary, is perfect, simple, and homogeneous—soul or spirit, which, as moving the elements into combinations of order and beauty, is endued with the faculty of knowing and surveying whatever was, and is, and shall be. Archelaus rather abandoned than advanced the views of his master Anaxagoras, and in him, as the teacher of Socrates, the Ionian school became extinct before the more extensive development of the Socratic philosophy. (Ritter, *Geschichte d. Ionischen Philosophie;* and Brandes, *Geschichte d. Griech.-Röm. Philos.*)

IONIAN SEA. [IONIA.]

IONIC DIALECT, the softest of the four written varieties of the Greek language, was spoken in the Ionian colonies of Asia Minor, and in several of the islands of the Ægean Sea. As the new Ionic, it is distinguished from an older, which was the common origin of itself and the Attic. The old Ionic was widely diffused, and its use was co-extensive with the Ionian settlements in the Peloponnesus and Northern Greece. (Thirlwall, *History of Greece*, i., 123.) The language of epic poetry arose out of this original tongue, which after the Dorian conquest passed, on the one hand, with the fugitives into Asia Minor, while, on the other, it continued to be spoken, for awhile at least, by the conquered peasantry who remained in Greece Proper. This tradition, which however, like most of the earlier traditions of Greece, is involved in great obscurity, may perhaps serve to explain (what in the common legends of Homer is otherwise inexplicable) the similarity of the language employed by Homer and Hesiod, who, though near to each other in time, were widely separated in the supposed scenes of their poetical labours. (*Ibid.*, ii. 120.) This first matured form of the Ionic has been called the epic, and was faithfully adhered to as the standard of Greek epic and elegiac composition by all subsequent writers of epos or elegy, which also owed its birth to Ionians.

On the formation of the new Ionic, or simply the Ionic, great influence was exercised by the commerce of the Ionians, and especially by their intercourse with the soft and effeminate Asiatics. Neglecting the combination of strength with softness which gave to the epic dialect its characteristic fulness of tone, the Ionians attended only to mellowness and euphony, to attain which it softened the aspirates, accumulated vowels, and laid aside every broader and harsher sound. Herodotus (i. 142) distinguishes four varieties (*χαρακτῆρες γλώσσης*) of the new Ionic, in one of which he wrote, and, though a Dorian, has left us the best and most complete specimen of it. [HERODOTUS; HIPPOCRATES.]

IONIC ORDER. [CIVIL ARCHITECTURE; COLUMN.]

IONI'DIUM, a genus of violaceous plants, inhabiting the tropical parts of America. It resembles Viola itself in most respects, but its sepals are not prolonged at the base into appendages, and the lower petal is not spurred. Several species are used medicinally. I. Ipecacuanha and some others have emetic roots.

IÖRA, or JORA, a genus of birds established by Dr. Horsfield, and placed by Mr. Swainson among his *Brachypodinæ*, or short-legged thrushes. [MERULIDÆ.]

IOS. [ARCHIPELAGO, GRECIAN.]

IPECACUANHA is an emetic substance, the root of several plants growing in South America. All the kinds have nearly the same ingredients, but differ in the amount of the active principle which they respectively contain, termed emeta. The best is the annulated, yielded by the Cephaëlis Ipecacuanha, a small shrubby plant, native of Brazil and of New Granada. Of this sort there are three varieties, namely, the brown, red, and grey, or grey-white, called also greater annulated ipecacuan. As this is the only sort sent from Rio Janeiro, it is sometimes called Brazilian or Lisbon ipecacuan. It is sent in bales and barrels

The root is in pieces from two to six inches long, and about the thickness of a straw, much bent or twisted, either simple or branched, with a remarkably knotty character, owing to numerous circular depressions or clefts, which give the whole an appearance of a number of rings; and hence the term annulated. It consists of a central axis called *meditullium*, and an external portion, called the *cortical* part. Each contains emeta; but by far the greater portion exists in the cortical. Of the three varieties of annulated ipecacuan the brown contains 16 per cent. of emeta, while the red contains only 14 per cent.: the grey has not been analyzed.

Another sort of ipecacuan is obtained from the Psychotria emetica: this kind contains only 9 per cent of emeta, and the undulated or amylaceous ipecacuan, the produce of the Richardsonia scabra, holds only 6 per cent. of emeta, with 92 per cent. of starch. Besides these, the roots of numerous other plants are used in tropical countries as emetics, and often termed ipecacuan.

The dust or powder of ipecacuan applied to any mucous surface causes irritation and increased secretion from the part. It is chiefly employed to excite the stomach either to augmented secretion, or to invert its action, and effect vomiting. It is also capable, by being combined with other substances, of being directed to the skin, and producing increased perspiration. When given in very small doses, it improves the appetite and digestive powers; in a somewhat larger dose, it acts on the intestines; but in a still larger, it inverts the action of the stomach, and occasions vomiting. It may therefore be used in a great many diseases, such as indigestion, dysentery, rheumatism, common colds, croup, &c. [EMETA; EMETICS; DIAPHORETICS; ANTIDOTES.]

IPHICRATES, an Athenian general, most remarkable for a happy innovation upon the antient routine of Greek tactics, which he introduced in the course of that general war which was ended B.C. 387 by the peace of Antalcidas. This, like most improvements upon the earlier methods of warfare, consisted in looking, for each individual soldier, rather to the means of offence than of protection. Iphicrates laid aside the weighty panoply, which the regular infantry, composed of Greek citizens, had always worn, and substituted a light target for the large buckler, and a quilted jacket for the coat of mail; at the same time he doubled the length of the sword, usually worn thick and short, and increased in the same, or, by some accounts, in a greater proportion, the length of the spear. It appears that the troops whom he thus armed and disciplined (not Athenian citizens, who would hardly have submitted to the necessary discipline, but mercenaries following his standard, like the Free Companions of the middle ages), also carried missile javelins; and that their favourite mode of attack was to venture within throw of the heavy column, the weight of whose charge they could not have resisted, trusting in their individual agility to baffle pursuit. When once the close order of the column was broken, its individual soldiers were overmatched by the longer weapons and unencumbered movements of the lighter infantry. In this way Iphicrates and his targetiers (peltastæ), as they were called, gained so many successes that the Peloponnesian infantry dared not encounter them, except the Lacedæmonians, who said in scoff that their allies feared the targetiers as children fear hobgoblins. They were themselves taught the value of this new force, B.C. 392, when Iphicrates waylaid and cut off nearly the whole of a Lacedæmonian battalion. The loss in men was of no great amount, but that heavy-armed Lacedæmonians should be defeated by light-armed mercenaries was a marvel to Greece, and a severe blow to the national reputation and vanity of Sparta. Accordingly this action raised the credit of Iphicrates extremely high. He commanded afterwards in the Hellespont, B.C. 389; in Egypt, at the request of the Persians, B.C. 374; relieved Corcyra in 373, and served with credit on other less important occasions. (Xen., *Hell.*; Diod.; Corn. Nep.)

IPHIS. [LEUCOSIANS.]

IPOMÆA, a genus of plants of the natural family of Convolvulaceæ, which is very closely allied to Convolvulus, or Bindweed, whence has been derived its name. From the more minute investigations of modern botanists considerable changes have taken place in the nomenclature of the species sometimes referred to this genus and sometimes to other nearly allied genera. M. Choisy, who has most recently examined the Oriental Convolvulaceæ, excludes many species usually referred here, and forms the genus of the species of Ipomœa and Convolvulus of authors. Ipomæa has a 5-sepaled calyx, a campanulate corol, with five stamens included within it. Style single; stigma bilobed; lobes capitate; ovary 2-celled; cells 2-seeded; capsule 2-celled. The species are very numerous, and found in the tropical parts of Asia, Africa, and America. A few ascend the mountains in such latitudes.

Most of the species are ornamental; others have been removed to Quamoclit, Argyreia, Pharbitis, &c., and one of the most useful as an article of diet in tropical countries, to Batatas. B. edulis produces the tubers so well known by the name of *Sweet Potatoes*.

Like the kindred genus Convolvulus, which affords us scammony, many of the species of Ipomæa are useful for their purgative properties: thus the Jalap plant is of this genus; and in India, I. Turpethum and cærulea are useful for similar purposes. Of the last the seeds only are employed, and form the *hub-al-nil* of Arabian authors, which has been usually translated *granum Indicum*. *I. Turpethum*, probably so called from the Arabic *toorbud*, which is itself no doubt derived from the Sanscrit tripoota (from *tri*, three, and *poota*, the coat of a seed), or from *trivrit*, another name, as the plant is an Indian one, and its root has been long employed in India as a common purgative. The bark of the roots is the part employed by the natives, as it contains all the active properties, which they use fresh, rubbed up with milk. About six inches in length of a root as thick as the little finger they reckon a common dose. (Roxb.) It is reckoned an excellent substitute for Jalap, and is free from the nauseous taste and smell of that drug. The plant is a native of all parts of Continental and probably of Insular India also, as it is said to be found in the Society and Friendly Isles and the New Hebrides. (*Fl. Ind.*, ed. Wall. 2, p. 59.)

Ipomæa Jalapa.

I. Jalapa is a species which has only recently been accurately determined, though its root has so long and so extensively been employed as a powerful medicinal agent. The drug being exported from Vera Cruz was supposed to be produced in the hot country in its immediate neighbourhood, or in that of Xalapa, and *I. macrorhiza* of Michaux was supposed to be the plant, though this grows also in Georgia and Florida, where no jalap has ever been produced, and its root weighs from 50 to 60 lbs. This was sufficient to prove that it could not be the source of the officinal drug, which is seldom larger than the fist. Hum-

boldt was however well aware that 'the true Purga de Xalapa delights only in a temperate climate, or rather an almost cold one, in shaded valleys, and on the slope of mountains' (*New Spain*, vol. iii.); and the fact is important as showing that a temperate and not a hot climate is required for its cultivation elsewhere. Dr. Coxe, of Pennsylvania, received in 1827 directly from Xalapa several small Jalap plants, one of which he succeeded in growing to maturity, and which was ascertained by Dr. Nuttal to be an Ipomœa, and named by him *I. Jalapa*. Specimens and seeds, of which the latter have produced plants, were subsequently procured by Dr. Schiede from Chiconquiera, on the eastern declivity of the Mexican Andes, at an elevation of 6000 feet. This plant, it is now ascertained, was also known to Miller from seeds sent by Dr. Houston from Mexico, as in the 'Gardener's Dictionary' a plant agreeing in description with the true Jalap plant, and with smooth leaves, is described. The root of this plant is a roundish somewhat pear-shaped tuber, externally blackish, internally white, with long fibres proceeding from its lower parts. The stem is much disposed to twist, and rises to a considerable height upon surrounding objects. The leaves are heart-shaped and pointed, deeply sinuated at the base, entire, smooth, prominently veined upon their under surface, and supported upon long footstalks. The flowers are of a lively purple colour, and stand upon peduncles as long as the petioles. [CONVOLVULUS JALAPA.]

IPSAMBUL. [ABOUSAMBUL.]

IPSUS, BATTLE OF. [ANTIGONUS, p. 103.]

IPSWICH, a parliamentary borough and corporate town, capital of the county of Suffolk, and distant 69 miles north-east from London, is agreeably situated on the side of a hill near the junction of the rivers Orwell and Gipping. According to Camden, this town was antiently called Gippeswich, which name was derived from that of the neighbouring river Gippen, or Gipping, and thence gradually became changed into Yppyswyche and Ipswich. The town does not appear to be mentioned before the invasion of the Danes in 991, by whom it was pillaged, and the fortifications destroyed. In the Confessor's time, according to Domesday Book, 'Queen Ediva had two parts here, and earl Gwert a third, and there were 800 burgesses paying custom to the king.' The earliest charter conferred upon the town was granted by king John in the first year of his reign, and by it numerous privileges were acquired by the burgesses, of which privileges the chief were, that they should have a merchant's guild, with their own hanse; that no person should be lodged within the borough without the consent of the burgesses; that they should hold their lands and tenures according to the customs of free boroughs, &c. Henry III. increased the privileges of the burgesses, but in the reign of Edward I. the borough was seized by that monarch, on account of certain offences committed by the inhabitants, though it was afterwards restored to them with all its liberties. In the reign of Edward III. the municipal government appears to have been again taken away from the corporation, and committed to the sheriff of the county, by whom a keeper of the town was appointed, but the corporate government was soon restored, and the burghal privileges confirmed and extended by the subsequent charters of Richard II., Henry VI., Edward IV., Richard III., Henry VII. and VIII., Edward VI., Elizabeth, James I., and Charles I. In the reign of Charles II. this corporation, like many others, surrendered its charters and franchises to the king, but in the 36th year of his reign the borough was re-incorporated, with a new constitution, and by a charter of James II. the corporate officers were released from the oaths. The charters of John, Edward IV., Henry VIII., and 17 Charles II., as restored by the proclamation of James, are all considered as governing charters. By the 5 and 6 William IV., cap. 76, the council of the borough consists of a mayor, 10 aldermen, and 30 councillors. Ipswich has returned two members to parliament since the 25th year of Henry VI.

The revenue of the corporation, consisting of water rental, rents of lands, houses, mills, and other tenements, exceeds 2000*l.* per annum. The expenditure in 1828 amounted to 1529*l.* 19*s.* 1*d.*, and the corporation property is charged with a debt of 14,300*l.*

The streets of Ipswich, though well paved, and lighted with gas, are narrow and irregular, which is attributable to the remarkable circumstance that the town is not known ever to have suffered from fire, or even from the civil commotions which convulsed so many parts of the kingdom about the middle of the seventeenth century. There are many good buildings, and many extremely old, decorated with a profusion of curiously carved images. Most of the houses, even in the heart of the city, have convenient gardens adjoining them, which render it at once agreeable, airy, and salubrious. The water for the supply of the town rises from springs in certain lands which the corporation hold under long leases, and it is conveyed into the town by pipes laid down at their expense. The water rental, which forms a considerable part of the revenue of the corporation, has been the source of much discontent among the inhabitants, as the former claim a monopoly of the supply, and the latter complain that they are ill supplied. In the Report of the Commissioners on Municipal Corporations, 1835, the police of the town is described as being particularly inefficient.

The manufactures of the town consist chiefly in the spinning of woollen yarn, ship-building, sail-making, &c. Its commerce arises from the exportation of corn, malt, and other produce of the surrounding country. There is a harbour for light vessels formed by the æstuary of the Orwell, which is navigable at high water up to the bridge, except for vessels of large burthen, which lie at Downham Reach.

The principal public buildings are the churches of Saints Clement, Helen, Laurence, Margaret, Mary at Elms, Mary at Kay, Mary at Stoke, Mary at Tower, Matthew, Nicholas, Peter, and Stephen. To the northward of the church of St. Mary at Kay was formerly a house of Black Friars, called the Priory of St. Peter's. The extensive site of this convent was purchased by the corporation, and confirmed to them in 1572 by the appellation of Christ's Hospital. Part of this edifice is now occupied as an hospital for poor boys, in which they are maintained, clothed, and educated, but the number during the five years preceding 1835 had never exceeded sixteen. The revenue of the hospital is estimated at 400*l.* a year. In another part of the monastery is a spacious room wherein is deposited the town library, the keys of which are kept by the master of the grammar-school, and out of which every freeman is privileged to take away any book upon giving a proper receipt In the spacious refectory of the same building, and on the south side, is now held the Free Grammar-school, the date of the first establishment of which is not known, though it was certainly prior to the year 1477. But in 1524 Cardinal Wolsey having intimated to the university of Oxford his design of founding a college (now Christ Church), the priory of St. Peter's was surrendered to him in 1527, whereon he founded a school as a nursery for his intended college at Oxford, and this school is said for a time to have rivalled those of Eton and Winchester. Queen Elizabeth, in the second and third years of her reign, granted two charters for the regulation of the Grammar-school and of Christ's Hospital, At the present time the master has a salary of 150*l* a year; he is provided with a dwelling-house, and the appointment is for life. Since the Report of the Commissioners on Charities a committee has been appointed to investigate the endowments of the Grammar-school. They state that the original endowment under the charter of Queen Elizabeth was 38*l.* 13*s.* 4*d.* per annum, which with some subsequent bequests makes an aggregate annual income of 66*l.* 6*s.* 8*d.*; but it does not appear from what source the additional funds are derived in order to liquidate the master's salary of 150*l.* and to defray the other expenses of the establishment. Ipswich is in the diocese of Norwich. The livings are three rectories, of the respective annual net values of 326*l.*, 337*l.*, and 82*l.*, and seven paid curacies of the net value of 175*l.*, 115*l.*, 80*l.*, 103*l.*, 150*l.*, 138*l.*, and 103*l.* The borough is divided into fourteen parishes, the aggregate population of which in 1831 was 20,201 persons. (Gough's *Camden's Britannia*; Carlisle's *Endowed Schools*; *Beauties of England and Wales*; *Parliamentary Papers*, &c.)

IRAK AJEMI. [PERSIA.]

IRAK ARABI. [BAGDAD.]

IRAPUATO. [MEXICO.]

IRELAND, the second in size of the British islands, and the second largest island of Europe, lies west of Great Britain, in the Atlantic Ocean. The general maps of Ireland at present published are too imperfect to give the means of stating its position more accurately than that it lies between 51° 25′ and 55° 22′ N. lat. and 5° 27′ and 10° 35′ W. long. The arm of the Atlantic which separates Ireland from Great Britain, and bounds it on the north-east, east, and

south-east, is narrowest at its northern extremity, where it is called the North Channel, and the opposite coasts approach within 14 miles, between the Mull of Cantyre in Scotland and Fair Head in the county of Antrim. Southward from this, that part of the channel which contains the Isle of Man expands to a breadth of 120 miles, between the coasts of Louth and Lancashire, and bears the name of the Irish Sea. Being again contracted by the projecting coast of Wales to a breadth of about 65 miles, it assumes the name of St. George's Channel, which it bears until it expands into the Atlantic at its southern extremity. The remainder of the coast-line on the north-west, west, and south-west is formed by the Atlantic Ocean. The chief lines of communication between Ireland and Great Britain are from Londonderry to Glasgow, 138 miles; from Belfast to Glasgow, 107 miles, and to Liverpool, 156 miles; from Donaghadee to Portpatrick, 21 miles; from Dublin to Liverpool, 130 miles, to Holyhead, 63 miles, to Port-Dinnlleyn, 70 miles; from Waterford to Bristol, 222 miles; from Cork to Bristol, 268 miles—sailing distances.

According to the Map published by the Society for the Diffusion of Useful Knowledge, the greatest length of Ireland, in a line nearly from north to south, is from Bloody Farland Point in the county of Donegal to the Old Head of Kinsale in Cork, 245 miles; and the greatest breadth, from Achill Head in the county of Mayo, on the west, to the mouth of Loch Strangford in the county of Down, a little to the north of east, 200 miles. In an oblique direction the greatest length is, from Fairhead in the county of Antrim to Mizen Head in the county of Cork, 306 miles, in a line bearing north-north-east by south-south-west. Pending the completion of the Ordnance Survey of Ireland, nothing can be stated with certainty regarding the area of Ireland. It is however estimated in the Map published by the Society for the Diffusion of Useful Knowledge, at 18,484,343 statute acres, or 28,881 statute square miles, of which 215,252 statute acres are under water. Another estimate made in 1831 is as follows:—

	Statute Acres.
Dry land	14,603,473
Unprofitable, mountain and bog	5,310,736
Lakes	455,399
Total .	20,399,608;

but this is probably above the true amount.

General Features.—The general form of the island is that of an oblique parallelogram, the longer diagonal lying between Mizen Head on the south-west and Fair Head on the north-east, and the shorter between Erris Head on the north-west and Carnsore Point on the south-east. The south-westerly portion of the island, which is most exposed to the Atlantic, is deeply indented with arms of the sea penetrating between rocky and mountainous promontories: the western shore in general is lofty and precipitous, and the eastern flat and little indented.

The most remarkable feature in the distribution of high and low land over the surface is the great limestone plain which occupies, with little interruption, almost the whole of the central district extending from the sea at Dublin on the east to the bay of Galway on the west, and from the counties of Sligo and Fermanagh on the north to the confines of Cork and Waterford on the south. The chief mountain-groups are either external to this plain, or rise in insulated ridges near its borders. Commencing from Dublin, where it touches the sea, the first interval between the limestone country and the Channel is occupied by the granite range of the Wicklow and Mount Leinster Mountains, which extends southward from the confines of Dublin and Wicklow into Carlow, and terminates near the confluence of the Barrow and Nore. From the flanks of this chain a clay-slate formation extends on the one hand into the eastern portion of Kildare, and on the other to the sea, forming the more cultivable portions of Wicklow, and almost the entire of Wexford; this latter district is interspersed with protruded masses of quartz and greenstone. Abutting on the southern extremity of this granite range commences a series of mountain-groups skirting the limestone plain on the south. The main constituent of these elevations is clay-slate and old conglomerate supporting flanks of yellow sandstone. One group, that of the Gaultees in Tipperary, is entirely insulated by the limestone, which also occupies several longitudinal valleys of the external district and in some places penetrates to the sea. This is the most extensive mountain district of Ireland. Commencing from the east the Slievenaman, Knockmildown, and Gaultee ranges extend in successive elevations of from 2000 to 3000 feet across the south of Kilkenny, Tipperary, and Limerick; after subsiding under the coal district which spreads from Limerick over the north-east of Kerry, they rise again towards the Atlantic, where Mount Brandon terminates the series in a lofty promontory which separates the bay of Dingle from the mouth of the Shannon. Southward from these groups the same formation occupies the entire counties of Cork and Kerry; the elevations here towards the east are moderate and the country fertile, but they spread over a wider surface and attain a greater altitude as they trend towards the sea, occupying the whole western part of Cork and the southern portion of Kerry with precipitous and sterile ridges, among which MacGillicuddy's Reeks in Kerry rise to the height of 3404 feet, being the highest ground in Ireland. Northward from Dingle Bay the limestone district again touches the sea, but throughout the western parts of Limerick and Clare it is overlaid by the great Munster coal-tract, from under which it again emerges on the south side of the bay of Galway. North and west of Galway the space between the limestone plain and the sea is again occupied by mountains. An extensive tract of granite with peaks of quartz and greenstone rising to the height of 2400 feet forms the northern boundary of the bay of Galway, and from this point northward to Killalla Bay a series of primitive rocks consisting chiefly of mica-slate and protruded masses of quartz is interposed between the Atlantic and the inland plain, except in one instance where the limestone reaches to the sea through the low country connecting the plains of Mayo with the head of Clew Bay. A primitive ridge of mica-slate and granite, nearly surrounded by the limestone which intervenes between it and the coast, prolongs this district northward and westward through Sligo to within a short distance of the borders of Donegal, where it subsides to rise again in that extended primitive formation which occupies almost all the county of Donegal and a great part of the counties of Derry and Tyrone. The north-western portion of this district consists of granite and quartz with numerous veins of primitive limestone, which is also of frequent occurrence throughout the great field of mica-slate that constitutes the remainder and rises in mountains from 1500 to 2500 feet high. This district is succeeded on the east by the great trap-field of Antrim, which overlies it through an extent of nearly 800 square miles: the cap of trap is supported throughout by a bed of chalky white limestone reposing on lias, the denuded edges of which give an extraordinary variety of colouring and structure to the cliffs of that coast: the substratum of mica-slate protrudes from below the superincumbent masses at the north-eastern extremity of the field, and crossing the Channel re-appears in Scotland. The clay-slate tract which succeeds the trap-field on the south and west, extending over Down and Armagh into Monaghan, Louth, and parts of Cavan, Meath, Longford, and Roscommon, also re-appears on the opposite side of the Channel, forming the grauwacke district which extends from Portpatrick to St. Abb's Head on the Frith of Forth. The granite group of the Mourne Mountains and the granite and greenstone group of Slieve Gallion occupy a considerable portion of this clay-slate tract, protruding in conspicuous masses in the southern parts of Down and Armagh to a height of 2500 feet and upwards. This completes the circuit of the interior plain which extends between the last-mentioned district and Dublin to the sea.

The principal detached groups which occur within the limestone plain are the Slieve Bloom and Slieve Baughta ranges, consisting of nuclei of clay-slate supporting flanks of red and yellow sandstone, which extend to a considerable distance on each side of the valley of the Shannon in the counties of Tipperary and Queen's County, and Clare and Galway respectively. A tract of old red sandstone rises into a chain of moderate elevation on the borders of Roscommon and Sligo in the north-west part of the plain, and several greenstone elevations diversify its surface in the centre and south-west.

The limestone-plain likewise contains six coal-districts, the Leinster, or Castlecomer district, on the south-east; the Slieve Arda, or Tipperary district, on the south; the Munster district, extending through parts of the counties of Cork, Kerry, Limerick, and Clare, on the south-west; the Loch Allen district, round the source of the Shannon, on the north-

west; and the Monaghan and Tyrone districts, on the north there is also a coal district of small extent in the north-eastern extremity of the county of Antrim. The coal raised in the southern districts is anthracite, or blind-coal; that raised in the districts north of Dublin is bituminous.

In addition to these the central district of Ireland contains upwards of one million of acres of bog, comprehended for the most part within that portion which would be embraced by lines drawn from Wicklow to Galway, and from Howth-head to Sligo. The greater portion of these bogs lies west of the Shannon in the counties of Galway, Roscommon, and Mayo; the remainder, extending in various tracts through King's County, Longford, Westmeath, and Kildare, is known collectively as the Bog of Allen. Numerous ridges of limestone-gravel, called Eskers, surrounding these several divisions, offer an unlimited supply of the material best adapted for their improvement. It is calculated that an expense of 1*l.* 5*s.* per acre would be sufficient for the drainage of these bogs, which are at present inaccessible and useless for the purposes of turbary.

Besides these encumbrances the lower carboniferous limestone, which constitutes the central plain, is overlaid in many tracts towards the borders of the district by the upper or splintery limestone, and this is generally accompanied by a craggy and rough surface: such is the case in the vicinity of each of the coal districts and throughout the counties of Sligo, Fermanagh, Cavan, and Leitrim. These districts contain numerous caverns, and streams sinking into subterranean channels are here of frequent occurrence.

By much the greater part of the central plain however is unincumbered, and has the pure carboniferous limestone for its substratum. Throughout these districts the soil is rich and sweet, and the surface gently undulating. The mountain groups and waste lands on the whole occupy a comparatively small portion of the entire island, and many of the districts lying without the central plain rival the richest limestone lands in easiness of access and fertility.

Rivers and Lakes.—From the arrangement of the mountain groups round the borders of the central plain the courses of the greater number of the rivers of Ireland are necessarily short. Of those which drain the external districts the chief are the Blackwater and Lee in Cork, the Foyle in Donegal and Derry, the Bann and Lagan in Antrim and Down, and the Slaney in Wexford. The rivers of the central district have longer courses and a much greater body of water. The chain of Slieve Bloom and the low range of the Eskers divide the central plain longitudinally into two unequal portions, of which the western division is by much the greater. The eastern or smaller division is again subdivided by the summit-level of the bog of Allen into a northern district, the waters of which discharge themselves into the Irish Sea by the Boyne, and a southern district, which sends its drainage in an opposite direction into the Atlantic by the united streams of the Barrow, Nore, and Suir, all navigable rivers. The western division, which much exceeds the united basins of these several rivers, is drained solely by the Shannon, which, from its great body of water and course through a flat country, possesses the extraordinary advantage of being navigable from its source to its mouth, a distance of nearly 210 miles. Those portions of the central plain which lie beyond the basins of the Shannon and Boyne discharge their chief drainage into a series of lakes which skirt the limits of the limestone country on the west and north. The lakes of Galway and Mayo form such a series, separating the primitive district of Connaught from the plain on the west; the extended line of Loch Erne in like manner drains that portion of the central plain which stretches towards the primitive district of Donegal and the high lands of Tyrone on the north; and Loch Neagh collects the waters of the remainder by the Blackwater River on the north-east. The other principal lakes of Ireland lie within the basin of the Shannon, those of most consequence being merely expansions of that river. The water-power afforded by the different rivers and natural dams of Ireland is greater than in any equal extent of accessible country in Europe. The surface of all the lakes in Ireland is estimated at 215,252 statute acres, or 336 square miles.

Climate.—There is but a small portion of Ireland which is more than fifty miles distant from the sea-coast, and on three sides of the island the Atlantic Ocean extends uninterrupted: hence the climate is more moist and less liable to severe cold than in any of the neighbouring countries. On an average of five years ending with 1829 the annual quantity of rain which fell at Cork in the southern extremity of the island was 35 inches, and in a like calculation for Derry, at its northern extremity, the average annual quantity was 31 inches; being in both cases considerably above the average quantity for most parts of Great Britain, though much below the average at Kendal, Keswick, and a few other places. Frosts are rarely severe in Ireland, and snow does not lie so long as in England; neither are thunder-storms of so frequent occurrence or of so formidable a character. The extension of tillage has contributed in a considerable degree to lessen the extreme moisture complained of by early historians; and to the quantity of dark-coloured earth now annually turned up intelligent writers attribute a fact often remarked by old persons, that the winters have latterly become much milder. The prevalent winds are from the west and south, and these are usually accompanied by a mild state of the atmosphere. Easterly winds are keen, and much dreaded by invalids. Instances of longevity are numerous, and the population generally healthy.

The chief characteristics of the scenery of Ireland are freshness and verdure: the surface is less rugged than that of Scotland, and more varied and undulating than that of England; it is however generally deficient in timber. The works of various tourists have latterly attracted much attention to the natural beauties of the southern and western districts.

History and Antiquities.—In the various names of Ireland, as known to the classic writers, Iris, Iernis, Iuvernis, Hibernia, &c., the radical *Ir* or *Eri*, by which it is still known to its own natives, is plainly traceable. It is customary among the Irish to indicate a country by the affix *Hy* or *Hua*, sometimes written *O*, as in the case of proper names, signifying literally 'the (dwelling of the) sons or family of,' such as Hy-Mania, Hy-Tuirtre, Hy-Brazil, &c. In adding this affix to names beginning with a vowel it is optional to insert a consonant to prevent the concurrence of open sounds, thus *Hy-v-Each*, meaning the country of the descendants of Each or Æacus. Again, this affix requires the genitive, which in *Eri* is *Erin*, and thus all variations of the name, from the *Iris* of Diodorus Siculus, and the *Ir land* and *Ireland* of modern times, to the *Iernis* (*Hy-Ernis*) of the Orphic poems, and the *Hibernia* (*Hy-b-Ernia*) of Latin writers, would seem to be accounted for.

The name *Scotia* does not appear to have been applied to Ireland till about the end of the third century, from which time to the beginning of the eleventh it continued to indicate that country exclusively.

The Scoti, who were in possession of the island at the time of the introduction of Christianity, appear to have been to a great extent the successors of a people whose name and monuments indicate a close affinity with the Belgæ of Southern Britain. A people also called Cruithne by the Irish annalists, who are identifiable with the Picts of Northern Britain, continued to inhabit a portion of the island distinct from the Scoti until after the Christian mission; and it is observable that the names of mountains and remarkable places in that district still strikingly resemble the topographical nomenclature of those parts of North Britain which have not been affected by the Scotic conquest. The monuments and relics which attest the presence of a people considerably advanced in civilization at some period in Ireland, such as Cyclopean buildings, sepulchral mounds containing stone chambers, mines, bronze instruments and weapons of classic form and elegant workmanship, would appear to be referrible to some of the predecessors of the Scoti, and indicate a close affinity between the earliest inhabitants of Ireland and that antient people, by some referred to a Phœnician origin, whose vestiges of a similar kind abound throughout the south and south-west of Europe.

The Scoti were not builders in stone, at least in their civil edifices, nor did they use bronze implements. Their own tradition is that they came originally from Scythia, by which is meant the north-eastern part of central Europe, which appears to be confirmed by the fact that the antient topography of the country, in districts where the Scotic invasion has not wholly obliterated it, points at the Welsh language as the nearest representative of that spoken by the predecessors of the Scoti, and that the chief distinctions which at present exist between the Irish and Welsh languages are referrible to a Gothic or Northern European source.

The general conversion of the Irish Scots to Christianity took place in the earlier and middle portion of the fifth century. The principal instrument in effecting the change was Patrick, who landed in Ireland on this mission in the year 432. Before this time, Christianity had made some progress, but the mass of the people were heathens. The form of church government introduced by Patrick was episcopal: in his doctrine and that of his successors for many centuries it is affirmed that there are no traces of those peculiar tenets which the Reformed churches rejected in the sixteenth century.

A considerable advance in civilization followed the introduction of the new religion. Greek and Roman literature got some footing among the clergy, and an improved system of architecture became requisite for religious edifices. The Irish round towers are now generally ascribed to an ecclesiastical origin, and are supposed to have been erected during the sixth, seventh, and eight centuries, which form perhaps the most prosperous epoch in the history of the country. From the end of the eighth century till the coming of the English, in A.D. 1170, the disputes of the petty princes of the country, and the frequent depredations of the Danes and other northern pirates, render the annals of Ireland a melancholy series of feuds and disasters.

Up to this time the government of the island had usually been vested in one monarch, who was entitled to certain subsidies and services from the petty kings of the provinces, and they in like manner levied contributions from the minor chiefs of territories. Dermod Mac Murrough, king of Leinster, having seduced the wife of one of these petty princes, and otherwise grown oppressive to his subjects, was expelled from his dominions in 1168, and fled for succour to Henry II. king of England, who, having already obtained a grant of Ireland from pope Adrian IV., readily gave his countenance to the restoration of Mac Murrough on receiving his oath of allegiance; but, being at that time engaged in a war with the French, he was unable personally to undertake the expedition. Several Welsh adventurers however, having obtained his licence to embark in the undertaking, fitted out a small armament, with which they landed in the county of Wexford, in the month of May, A.D. 1170. The conquest of the entire island was soon effected. In 1174, the king, coming over in person, received the submission of the Irish monarch, and of almost all the provincial and petty kings, and in the same year had his title confirmed, and the discipline of the Irish and English churches assimilated at a general synod of the Irish clergy held at Cashel.

The country was now portioned out among the Anglo-Norman conquerors, and with the introduction of English modes of tenure the erection of courts of law and appointment of executive authorities had their commencement. The twelfth year of the reign of king John, who succeeded his father as lord of Ireland, is the epoch to which the final division into counties is generally referred. This division appears to have embraced almost the entire of Ireland, although through subsequent reverses most of the counties in Ulster and Connaught ceased to be considered shire ground. These disasters were chiefly owing to the exorbitant powers enjoyed within their several territories by the great lords of the country, who finding the Irish customs more congenial to arbitrary authority, by degrees fell away from the exercise of the English law, and assumed the characters of despotic chieftains. In particular, the family of the De Burgho's in Ulster and Connaught, being released, by the murder of William earl of Ulster, in A.D. 1333, from the restraint which he had for some time exercised over them, seized the better part of the latter province and assumed Irish names; while the northern native Irish recrossing the river Bann, beyond which they had hitherto been confined, drove the English out of the north-eastern parts of Ulster, and narrowed the pale in that direction to the county of Louth. In like manner the families of Desmond and Kildare, having possessed themselves of a great part of Munster and Leinster, introduced the Irish customs on that side, so that on the accession of king Henry VIII. there was but an inconsiderable tract along the eastern coast in which the English law was fully recognised.

In this and the succeeding reigns of Elizabeth and James I., the English government having now the double motive of effecting a religious as well as a civil reformation in Ireland, applied themselves with great energy to the recovery of their authority, and, after a tedious series of rebellions and confiscations, succeeded at length, in the beginning of the seventeenth century, in making the entire island shire-ground, and planting a numerous Protestant proprietary in Ulster. The Reformed church had already been established in A.D. 1535; but the great body of the native Irish still continued attached to the Roman Catholic faith.

In October, 1641, a rebellion, having for its object the overthrow of the new establishment and the restoration of the old proprietors to their estates, broke out among the native Irish, and was afterwards joined by the chief Roman Catholic nobility and gentry: the result of the civil wars which ensued was the suppression of the Irish and Roman Catholic party, and a general confiscation of their lands.

On the accession of James II., and the prospect of a re-establishment of the Roman Catholic church, the same party again rose to considerable power, and on king James retiring to Ireland after the revolution of 1688, they supported his cause through an arduous war of three years' continuance, until after the defeats of the Boyne and Aughrim, when they finally capitulated at Limerick, on the 3rd October, 1692. Extensive confiscations followed this civil war also. The military men and other more active members of the Roman Catholic party left the country, and entered into the service of different states on the Continent, where they very generally distinguished themselves by their fidelity and bravery. Those who remained, still constituting the bulk of the population of the island, were henceforth treated with extreme severity; yet, notwithstanding the harshness of the penal laws from time to time enacted against Roman Catholics, the country generally prospered during the century of uninterrupted tranquillity that ensued. The example of the American and French revolutions however having created a democratic spirit among many of the northern Protestants, and some of them having taken up arms in the year 1798, led to another rising among the Roman Catholic peasantry of much the same character with those insurrections in which their ancestors had unfortunately been so often engaged. This rebellion, being likewise suppressed, led the way to the Act of Union, by which the parliament of Ireland, which had of late years enjoyed an absolute independence of all power but the crown, was merged in that of the United Kingdom, A.D. 1800.

The Irish Roman Catholics, who had greatly increased in wealth and numbers since the time of the Union, were in the year 1829 admitted generally to the political privileges enjoyed by Protestant dissenters. The Reform Act considerably added to their political influence, and various changes are now in progress and operation, the general tendency of which is to give them a large share of political power in the state.

Population.—Notwithstanding the numerous colonies of British who have from time to time settled in Ireland, the great bulk of the population is still of the native Irish race. The native Irish are of a warm and imaginative disposition, with much natural eloquence and a strong perception of humour; they are very hospitable, and individually brave; the prevailing vices of the national character are improvidence and a disposition to riotous excitement. During the wars in the reign of Elizabeth they were reduced to considerably less than a million in number, but in the subsequent progress of the population they have increased in a much more rapid ratio than either their English or Scottish fellow-countrymen. The following table exhibits the numbers of the entire population at the several dates below:—

Date.	How ascertained.	
1672	By Sir William Petty . . .	1,320,000

1792	Estimated by Dr. Beaufort	4,088,226
1805	Mr. Newenham's estimate	5,395,456
1821	Under Act 55 Geo. III., c. 120	6,801,827
1831	Under Act 1 Will. IV., c. 19	7,767,401
1834	Estimated by the Commissioners on Public Instruction	7,954,100
1837	Estimated by Irish Railway Commissioners	8,523,750

The distribution of this very large population is chiefly towards the eastern side of the island; the west and north-west are comparatively thinly inhabited. The general condition of the people is considerably improved of late years, but still there is a very numerous class of peasantry in the west and north-west whose state is extremely wretched. The average rate of wages for agricultural labourers throughout the entire country is about 8½d. per day, and the average employment about twenty-two weeks of six working days each in the year. The classes into which the population was divided in 1831 appear in the census of that year as follows:—Families chiefly employed in agriculture, 884,339; ditto chiefly employed in trade, manufactures, and handicraft, 249,369; ditto not comprised in the preceding classes, 251,368; males 3,794,880; females 3,972,521; total 7,767,401 persons, forming 1,385,066 families, inhabiting 1,249,816 houses.

In the same year the number of agricultural occupiers employing labourers was 95,339; of occupiers not employing labourers, 564,274; of male labourers employed in agriculture, 567,441; of males, 20 years of age, employed in manufactures, 25,746; employed in retail trade or in handicraft as masters or workmen, 298,838; of capitalists, bankers, professional and other educated men, 61,514; of labourers employed in labour not agricultural, 89,876; of other males 20 years of age, except servants, 110,595; of male servants 20 years of age, 54,142; of ditto under 20 years, 44,600; of female servants, 253,155.

Religion.—In 1834, according to the returns of the Commissioners of Public Instruction, there were in Ireland 6,431,008 Roman Catholics; 852,676 members of the Established church; 642,356 Presbyterians; 21,808 other Protestant dissenters: and 6254 whose religion could not be ascertained; being in the proportion of 4½ Roman Catholics nearly to one Protestant of whatever denomination.

Education.—In 1834 there were in Ireland 9657 daily schools, being in the proportion of one school to each 824 of the entire population, educating 633,946 young persons, being in the proportion of 7·97 per cent. of the entire population under daily instruction. Of these schools 5653 were supported wholly by payments from the children, and 4004 were supported wholly or in part by endowment or subscription: of the latter class there were in the above year 892 in connection with the National Board of Education; 203 in connection with the Society for Discountenancing Vice; 115 in connection with Erasmus Smith's fund; 235 in connection with the Kildare-street Society, and 618 in connection with the London Hibernian Society. There is a University at Dublin, a Roman Catholic College at Maynooth, and various superior establishments for education in other towns. [Belfast; Dublin; &c.]

Crime.—During the year 1836 there were 23,891 persons committed for trial or bailed, of whom 7769 were charged with offences against the person; 671 with offences against property committed with violence; 6593 with offences against property committed without violence; 500 with malicious offences against property; 214 with forgery and offences against the currency; and 8144 with other offences not included in the above classes. The proportion of the offenders to the entire population was 1 in 325, and the male offenders were to the female as 0·82 to 0·18. Of the total number of offenders 6744 males and 490 females could read and write; 3898 males and 912 females could read only; 7435 males and 2595 females could neither read nor write; and of 1542 males and 275 females the instruction could not be ascertained. The total number of convictions in that year was 18,110.

Productive Economy.—*Agriculture.*—The agricultural produce of Ireland was estimated, in the year 1832, at 36,000,000*l.* per annum, raised off 14,603,473 acres. This falls short, by nearly one half, of the amount of produce yielded by an equal area in Great Britain; and yet in the latter country there are only *two* agricultural labourers for every *five* for the same quantity of land in Ireland. Hence it appears that the productive powers of the soil of Ireland, as compared with those of the soil of Great Britain, are little more than half developed. The causes of this deficiency are to be sought in a bad system of agriculture, small farms, and want of capital. A marked improvement is however observable both in the quantity and quality of Irish agricultural produce within the last ten years. The increase in quantity will be apparent from the following table of the comparative exports of some of the principal articles of such produce in the years 1825 and 1835:—

Exports of Irish Produce in 1825 *and* 1835.

Commodities.	Quantity.		Increase between these Periods.	Estimated Value for 1835.	
	1825	1835.		£	s

The earnings of the agricultural labouring classes, including occupiers labouring on their own land, in 1836, are estimated at 6,844,500*l.*

The value of the peat annually raised from the bogs for fuel is very considerable. At 35 kishes or loads per family, which is the estimate of Mr. Wakefield, averaging 9*d.* per kish, the value of the quantity required for fuel in 1831, calculating only on the families employed in agriculture, would be 1,160,694*l.*; but this is probably too low an estimate, as it only exceeds by about 200,000*l.* the value of the imported and native coal consumed in the same time.

Mining.—The annual average produce of the mines worked by the Mining Company of Ireland in 1836 was about 150,000*l.*, and of the mines worked by other parties about 220,000*l.* The export of lead and copper ore in 1835 amounted to 477,660 cwts., of an estimated value of 179,388*l.* The mines and quarries at present open are not however worked to their full extent; this branch of industry is indeed still in its infancy in Ireland.

Fisheries.—In the general coast fishery in the year 1836 there were employed—decked vessels 215, tonnage 7099 tons; half-decked ditto 870, tonnage 10,292 tons; open sail-boats 1812, tonnage 9178 tons; and row-boats 7864 total number of fishermen 54,119; showing a considerable decrease since 1830, when the number of fishermen employed was 64,771. The earnings of each fisherman having a share in the produce being estimated at from 3*s.* 6*d.* to 4*s.* per week on an average through the year would give the nett profits of the produce for 1836 at 527,650*l.* The gross annual produce of the coast and river salmon fisheries does not amount in all to 10,000*l.*

Manufactures.—The value of the unbleached linens sold in the several counties of Ulster in the year 1824 was 2,109,305*l.*, and in all Ireland for the same year 2,580,697*l.* Since that time there is no authentic return; but the introduction of linen-yarn spinning-machinery has latterly given the linen trade an extraordinary impetus in the northern counties of Ulster. The exports of linen in the year 1835 amounted to 70,209,572 yards, of an estimated value of 3,725,054*l.*, being an increase on the linen export of 1825 of 15,095,057 yards.

The cotton trade is carried on to a considerable extent in

the same district, and in one large establishment in the county of Waterford; but it has latterly declined, and many of the mills originally designed for the spinning of cotton are now turned to the manufacture of linen yarn, the demand for which is much greater than the present means of production can meet. The export of cotton fabrics, which in 1825 amounted to 10,567,458 yards, in 1835 was only 1,039,088 yards, estimated at a value of 15,253*l*. In the latter year there was however an export of cotton in other forms of manufacture to the amount of 132,880*l*.

Since the year 1822 the woollen trade has declined considerably. In that year there were in and about Dublin forty-five establishments, the annual value of the goods produced in which, if estimated at present prices, would be about 200,000*l*. The total value of the woollens now manufactured in the same district is about 90,000*l*. In the districts of Cork, Kilkenny, Moate, and Carrick-on-Suir, where the woollen trade formerly flourished, the present value of the woollens annually manufactured does not exceed 20,000*l*.; and the flannel trade of Wicklow and Wexford, which in 1822 was estimated at 56,000*l*. for the annual value of its produce, may now be considered as extinct. The manufacture of worsted and stuff articles is the only branch of this trade which has increased within the last sixteen years: it is now carried on to a considerable extent at Mount Mellick and Abbeyleix in the Queen's County. Such of the general trade as remains is however considered to be at present in a healthy state, and reasonable hopes are entertained of a progressive improvement. The value of the different woollen manufactures exported in 1835 was 40,128*l*.: a considerable portion of this export was to the south of England, which is now more accessible to the Irish than to the northern English manufacturer. The silk manufacture is also much decayed: the export of silk fabrics in 1835 amounted to 21,740*l*.

In grinding, malting, brewing, and distilling, a great advance has been made in Ireland within the last fifteen years The number of corn mills in Ireland in 1835 was 1882; of corn-kilns, 2296: of distilleries, 95; of rectifying distilleries, 19; of breweries, 236; of paper manufactories, 57, of glass-works, 6; and of tobacco factories, 291. The export of oatmeal, flour, and wheatmeal, which now amounts to nearly one million and a half sterling annually, has grown up almost wholly of late years; so also the valuable export trade in porter.

Steam Power.—There were, in 1835, 151 steam-engines of from 1 to 100 horse-power each, employed in various manufacturing operations in the towns and neighbourhoods of Belfast, Clonmel, Cork, Dublin, Galway, Kilkenny, Limerick. Londonderry, Waterford, and Portlaw. Of these the first was erected in Belfast in the year 1806.

In addition to these there are upwards of 90 steam-vessels with engines of from 20 to 300 horse-power engaged in the British coast and canal traffic. Cork is now a station for steamers sailing to North America, and a steam communication is kept up during the summer months between Bordeaux and Dublin, and Hâvre and Belfast.

COMMERCE.—*Inland Traffic.*—The inland traffic of Ireland is almost wholly carried on either by high road or canal, there being but one railway of five miles in length at present in operation in the country. Another line of seven miles in length is however now in process of completion between Belfast and Lisburn. The extent of the various lines of inland navigation is as follows:—

	Miles.
Grand canal from Dublin to Ballinasloe, with its branches	164
Royal canal from Dublin to Tarmonbarry, with its branches	99
Lower Shannon navigation	44
Limerick navigation, river and canal	15
Middle Shannon, navigation	3[illegible]
Upper Shannon navigation	59
Lagan navigation, river and canal	28¼
Newry navigation, river and canal	16½
Tyrone navigation, river and canal	11¾
Lower Boyne navigation, river and canal	19
Slaney navigation, river and canal	16
Barrow navigation, river and canal	78
	589½
In addition there is now in progress the Ulster canal, joining the waters of Lough Neagh and and Lough Erne, of which there are completed	24
	613½

Being in all about one-fourth of the similar means of internal traffic existing in 1835 in an equal area in Great Britain.

The general direction of the traffic of Ireland is eastward, of the external traffic almost wholly so. With the exception of the transverse lines of the Royal and Grand Canal, the great bulk of the inland traffic lies towards and along the eastern coast from Londonderry to Cork inclusive.

Carrying Traffic.—The means of external traffic possessed by Ireland amount to less than one-fourteenth of those of England, and to rather more than a third of those of Scotland. The following table exhibits the number of vessels, with the amount of their tonnage, and the number of men and boys usually employed in navigating the same that belonged to the several ports of Ireland in the years below:—

	Vessels.	Tonnage.	Men.
On the 31st December, 1834	1536	119,398	8731
„ „ 1835	1627	131,735	9282
„ „ 1836	1635	128,469	9189

Here the proportion of seamen to tonnage is about 1 to 14; in the merchant-service of England the proportion is as 1 to 18 nearly This difference is to be accounted for by the superior size and better management of the English vessels, which require less manual labour. The general navigation of Ireland and its progress appear from the subjoined table, showing the number of vessels, with the amount of their tonnage and men (including their repeated voyages), that entered inwards and cleared outwards at the several ports of Ireland, from and to all parts of the world, during each of the years below:—

Shipping entered inwards in Ireland, from all parts of the World.

Year ending 5th January.	British and Irish Vessels.			Foreign Vessels.			Total.		
	Vessels.	Tons.	Men.	Vessels.	Tons.	Men.	Vessels.	Tons.	Men.

Total		17,394,813	7	11	15,337,097	4	6

Exclusive of the coasting trade, so as to exhibit the true excess of exports over imports, these totals for the year 1835 are—

	£	s.	d.
Exports	£16,693,685	6	1
Imports	10,918,459	4	4
Excess of Exports over Imports	5,775,226	1	9

The increase exhibited by the returns of this year over those of 1825 is very remarkable, showing an increased value on exports of 7,450,475*l.* 6*s.* 1*d.*, and on imports of 2,321,674*l.* 4*s.* 4*d.*

The principal article of import into Ireland is cotton goods, which in 1835 were imported to the amount of 1,419,364*l.*; in the same year, notwithstanding the active manufacture of linen yarn in Ulster, that article was imported to the amount of 1,217,900*l.* The next most important articles of import in that year were—tea, to the amount of 972,554*l.* 11*s.* 8*d.*; coal, 802,749*l.* 5*s.* 2*d.*; sugar, 774,930*l.*; tobacco, 743,115*l.* 7*s.* 10*d.*; woollen goods, 685,423*l*; haberdashery and apparel, 487,630*l.*; wool, 304,337*l.*; iron, 208,830*l.*; cast-iron, 89,130*l.*; wrought-iron and hardwares, 198,806*l.*; glass and earthenware, 128,709*l.*; wines 160,343*l.* 1*s.* 3*d.*; herrings, 124,084*l.*; hides, 163,221*l.*; tallow, 129,149*l.*; hops, 92,657*l.*; flax-seed, 84,329*l.*; salt, 65,718*l.* 14*s.*; leather, 30,840*l.*, &c.

Currency.—There are in Ireland seventeen banks and banking companies, with numerous branch establishments: the following is an estimate of the proportions in which their notes circulate in each of the four provinces, the total amount of notes being about 5,000,000*l*—

The province of Leinster	£1,700,000
" Ulster	1,400,000
" Munster	1,300,000
" Connaught	600,000
	£5,000,000

Between the years 1824 and 1831 there appears to have been an amount of government stock of the value of 14,181,100*l.* transferred to the credit of Irish fundholders.

GOVERNMENT.—*Representation.*—Ireland is represented in the imperial parliament by 105 members of the House of Commons, and 28 temporal and 4 spiritual peers in the House of Lords. The temporal peers are elective representatives for life; the spiritual peers take the office in rotation.

Civil Divisions.—Ireland is divided into four provinces and thirty-two counties. *Connaught* contains 5 counties, *Munster* 6 counties, *Ulster* 9 counties, and *Leinster* 12 counties. The counties are divided into baronies, and the baronies into townlands.

The following is a list of the counties of Ireland, with the population according to the last census, and the area in square miles:—

	Population.	Sq. Miles.
Antrim (Ulster)	325,615	1,107
Armagh (Ulster)	220,135	485
Carlow (Leinster)	81,988	330
Cavan (Ulster)	227,933	711
Clare (Munster)	258,320	1,141
Cork (Munster)	810,732	2,659
Donegal (Ulster)	289,150	1,829
Down (Ulster)	352,010	951
Dublin (Leinster)	380,167	294
Fermanagh (Ulster)	149,763	640
Galway (Connaught)	414,684	2,033
Kerry (Munster)	263,126	1,670
Kildare (Leinster)	108,424	597
Kilkenny (Leinster)	193,685	733
King's County (Leinster)	144,225	714
Leitrim (Connaught)	141,524	576
Limerick (Munster)	315,355	750
Londonderry (Ulster)	222,010	794
Longford (Leinster)	112,558	357
Louth (Leinster)	124,846	322
Mayo (Connaught)	366,328	1,599
Meath (Leinster)	176,826	899

Cork	2	Limerick	2	Youghall	1
Downpatrick	1	Lisburn	1		
Drogheda	1				
	14		28		39

In the Population Returns the number of parishes in each county is not stated; but it appears from some Diocesan Returns made in 1834 that the total number of parishes in the four provinces is 2348; that is, for the province of Armagh, 658; Dublin, 624; Cashel, 791; and Tuam, 275.

Ecclesiastical Divisions.—Ireland is divided into four ecclesiastical provinces and thirty-two dioceses. These di-

visions, although equal in number and corresponding in general situation, are in no instance co-extensive with the civil districts. The provinces are ARMAGH on the north, containing the dioceses of *Clogher, Kilmore, Ardagh, Meath, Armagh, *Dromore, Down, Connor, Derry, *Raphoe; TUAM on the west, containing the dioceses of *Kilmacduagh, *Clonfert, *Elphin, Tuam, *Killalla, *Achonry; DUBLIN on the east, containing the dioceses of *Kildare, Leighlin, Dublin, Ferns, *Ossory; and CASHEL on the south, containing the dioceses of *Waterford, *Lismore, Cashel, Emly, Cloyne, *Cork, *Ross, Ardfert and Aghadoe, Limerick, Killaloe, Kilfenora. The dioceses are divided into parishes, which are for the most part co-extensive with a certain aggregate of townlands. By the 3rd & 4th William IV., c. 37, it is enacted that the dioceses marked above with asterisks, forming in all ten bishoprics, when and as void, shall be united to certain other bishoprics: by the same act the archiepiscopal sees of Tuam and Cashel, on becoming void, are to be united to the archiepiscopal sees of Armagh and Dublin respectively. The present ecclesiastical establishment consists of four archbishops and twelve bishops, six of the bishoprics mentioned in the act having now lapsed.

The Roman Catholic establishment consists of four archbishops and twenty-three bishops, their provinces and dioceses being for the most part co-extensive with those of the Established church.

The Presbyterian body are divided into two sects; one, by much the more numerous, being in connection with the synod of Ulster, which agrees in doctrine and government with the church of Scotland; and the other with the synod of Munster and Remonstrant synod, among whom Unitarian opinions are prevalent. The Seceding body have also their synod.

The clergy of the Established church derive their revenue from church lands and tithes; those of the Presbyterian church from parochial stipends and an annual grant from government, called the *regium donum*; the Roman Catholic church is supported wholly by dues paid by the people.

Justice.—The law courts of Ireland are the Queen's Bench, Common Pleas, Exchequer, and Chancery. There is also, as in England, a bankrupt court, a court for the relief of insolvent debtors, a court of admiralty, with consistorial courts in the several dioceses, and a metropolitan ecclesiastical court. There are four judges in each of the courts of Queen's Bench, Common Pleas, and Exchequer. In the Court of Chancery there are the lord-chancellor and the master of the rolls. The office of vice-chancellor does not exist in Ireland. The courts of law sit during each term in Dublin, and the going judges hold assizes of Oyer and Terminer and gaol delivery twice a year in each county town. Courts of quarter-session are held in the several counties before assistant-barristers, and there are numerous minor courts in most of the towns and counties.

Executive.—The administration of the government is vested in the lord-lieutenant and privy-council, assisted by a chief secretary and an attorney and solicitor-general. The lord-lieutenants and magistrates of the several counties are appointed by the crown and lord-chancellor, and the sheriffs are generally nominated by the going judges and appointed by the lord-lieutenant.

The police, independent of the local police of the towns, in 1836, consisted of 4 inspectors, 1 superintendent, 10 resident magistrates, 155 chief constables of the first and 59 of the second class; 1232 constables; 6233 subconstables, and 277 horse of the constabulary force; and of 10 resident magistrates, 9 chief constables, 109 constables, 492 subconstables, and 10 horse of the peace preservation police: total expense of both forces, 382,460*l.* 12*s.* 11*d.*

In addition to this force there are generally from 15,000 to 20,000 soldiers of the line quartered in Ireland.

Finance.—The revenue of Ireland is derived from four sources; customs, excise, postage, and stamps. The following table exhibits a comparative view of the progress of this branch of the general revenue from the year preceding the Union.—Gross proceeds:

	1799			1810			1820			1837		
Customs	832,046	17	7	2,044,430	14	11	1,885,482	17	1½	2,036,738	2	3½
Excise	635,666	4	3	1,824,921	4	7½	2,295,377	19	4½	2,027,949	17	7¼
Post-Office	47,449	19	3	191,279	10	7	201,637	2	6¼	255,070	0	4
Stamps	56,902	17	7½	644,855	2	4½	448,088	14	2½	476,152	18	8¼
Fees and Imprest Monies										11,491	2	3
Total (gross)	£1,572,065	18	8½	£4,705,486	12	6	£4,830,586	13	2¾	£4,807,402	1	3

The rate per cent. for which these gross receipts have been collected has been greatly diminished of late years. In 1837 it was 11*l.* 13*s.* 4¾*d.*, including the expenses of the post-office department. The net proceeds in that year were 4,165,910*l.* 17*s.* 5¾*d.*

The general contribution of Ireland to the imperial revenue is however considerably greater than the amount appearing on these returns, in consequence of the large importation into that country of taxable commodities which have already paid duty in Great Britain.

County Cess.—The cost of making, repairing, and maintaining highways, bridges, gaols, &c., and keeping up the general machinery for the administration of justice and preservation of the public health, is supported by local assessments levied by the grand juries of the several counties. These annual assessments average about 800,000*l.* for the whole country.

A good account of all the sources from which information in Irish affairs might be drawn up to the year 1724 is given in Nicholson's 'Irish Historical Library,' 8vo., Dublin, 1724. Since that time various general histories have been published by Leland, O'Halloran, MacGeoghegan, Plowden, Moore, and others, with statistical accounts of most of the counties by compilers employed by the Royal Dublin Society. The 'Transactions of the Royal Irish Academy' have latterly thrown much light on the antiquities and natural history of the country, and numerous Parliamentary Reports and Papers have from time to time added to our statistical information. A geological Map and Memoir, recently published by the Commissioners on Railways, have also supplied a desideratum long felt by writers on Irish topography. The more particular authorities are given under the heads of the several counties.

IRELAND, NEW. [NEW IRELAND.]

IRE'NA. [ORIOLINÆ.]

IRENÆUS, SAINT, bishop of Lyon in Gaul, was a pupil of Polycarp, in Asia Minor (Iren. *adv. Her.* iii. 3, § 4; Eusebius, *Hist. Eccl.* v. 20), and a presbyter of Pothinus, bishop of Lyon. He carried a letter from the church of Lyon to Eleutherus, bishop of Rome, respecting some disputes which existed between them, in which he is honourably mentioned. On the martyrdom of Pothinus, at the age of ninety, in 177 A.D., Irenæus was elected bishop of Lyon. He discharged the duties of his office with exemplary diligence and faithfulness, and is said to have been the means of converting many pagans to the Christian religion. The place of his birth is not known; but it is probable from his name that he was a Greek, and from his early acquaintance with Polycarp that he was a native of Asia Minor. Critics differ considerably respecting the date of his birth: Dodwell places it about A.D. 97, Grabe about A.D. 108, Du Pin about A.D. 140, and Tillemont about A.D. 120. It is commonly supposed that he suffered martyrdom in the beginning of the third century; but it has been argued by many critics, from the silence of Tertullian, Eusebius, and most of the early fathers, that this is probably incorrect.

With respect to the works of Irenæus, we learn from Eusebius (*Hist. Eccl.* v. 20) 'that he wrote several letters against those which at Rome corrupted the true doctrine of the church; one to Blastus, concerning schism; another to Florinus, concerning the monarchy, or that God is not the

author of evil; and concerning the number eight.' Eusebius also mentions (v. 26) 'a discourse of Irenæus against the Gentiles, entitled, Concerning Knowledge; another, inscribed to a brother named Marcianus, being a demonstration of the apostolical preaching; and a little book of divers disputations.' Irenæus also wrote a letter to Victor, bishop of Rome, concerning the controversy about the time of holding Easter; and also 'Five Books against Heresies.' The last work is still extant; but all the rest have perished, with the exception of a few fragments. The original Greek of the 'Five Books against Heresies' has also been lost; we possess only a Latin translation of it, written in an uncouth style, which was made, according to Dodwell's computation (*Dissert. Iren.* v. 9, 10), about A.D. 385. This circumstance renders the work of little value in ascertaining the readings of the Greek Testament in the time of Irenæus, since the Latin translator appears to have quoted the text of Scripture according to the Latin version then in use.

It is difficult to determine at what period the 'Five Books against Heresies' were written, but they all appear to have been composed after Irenæus became bishop of Lyon, and to have been published at different times. Irenæus was well acquainted with heathen literature and the doctrines of the heretics of his time. His work is very valuable in an historical point of view, and has been highly commended by most of the fathers; though Photius (*Bibl.* c. 120) gives rather a different opinion of it, thinking 'that the purity of the faith with respect to ecclesiastical doctrines is adulterated by the false and spurious reasonings of Irenæus.'

Irenæus was a most diligent collector of apostolical traditions. He informs us, in many parts of his work, that he was well acquainted with several persons who had been intimate with the apostles. Many of his traditions are of a very curious kind. He affirms that Christ was at least 50 years old at the time of his crucifixion, and he asserts the most extravagant opinions with regard to the Millennium. Middleton, in his 'Free Inquiry' (p. 45-52), has given an interesting account of many of the opinions of this father.

The life of Irenæus has been written by Gervaise, Paris, 1723. His works have been published by Erasmus, 1526; by Feuardent, 1596; by Grabe, 1702; by Massuet, 1710; and by Pfaff, 1734. Some of the fragments published for the first time by Pfaff are supposed by Lardner (*Credibility of the Gospel History*, Works, ii., p. 189-191, ed. of 1831) to be spurious.

IRETON, HENRY, the eldest son of German Ireton, of Attenton, in Nottinghamshire, was born in 1610. He was entered at Trinity College, Oxford, in 1626, and having taken the degree of bachelor of arts, became a student of the Middle Temple. His legal studies were interrupted by the outbreak of the civil war; he entered the parliamentary army, and soon made such a proficiency in the military art, that it has been asserted that Oliver Cromwell learned its rudiments from him. In 1646 he married Bridget, Cromwell's eldest daughter, by which connexion and his own merit he gained a commission, first of captain of horse, and almost immediately afterwards that of colonel. He distinguished himself in the battle of Naseby, was taken prisoner by the royalists, but made his escape. Ireton was perhaps more than any other man the cause of king Charles's death; by intercepting a letter, he is said to have discovered that it was the king's intention to destroy him and Cromwell, and from that time he rejected any accommodation: he attended most of the sittings of the regicide court, and signed the warrant for Charles's execution. On the establishment of the Commonwealth he was appointed to go to Ireland, next in command to Cromwell. He was made president of Munster, and afterwards lord-deputy of Ireland. The greater part of the country submitted to him from fear of his cruelty, without striking a blow. While in the height of his successes he was seized, before Limerick, with the plague, of which he died on the 15th of November, 1651. His body was landed at Bristol, and lay in state at Somerset House. On an atchievement over the gate of Somerset House was the motto, 'Dulce et decorum est pro patria mori,' which was readily translated 'It is good for his country that he is dead.' He was buried in Henry the Seventh's chapel in Westminster Abbey; but the corpse was exhumed after the Restoration, gibbeted, and burnt at Tyburn.

He left one son, Henry, and four daughters. Ireton was revered by the republicans as a soldier, a statesman, and a saint. He was called the 'scribe,' from his skill in drawing up declarations, petitions, and ordinances. His antagonists allowed him to be an able but not a virtuous statesman; indeed, he appears to have been the most artful, designing, and deliberate man of his party. He refused a grant of 2000*l.* a year, which was offered to him out of the confiscated estate of the duke of Buckingham; and after his death the parliament, out of gratitude for his services, settled it upon his widow and children. (Noble's *Memoirs of the Cromwell Family*, vol. ii., No. 27.)

IRIARTE. [YRIARTE.]

IRIDA'CEÆ, a natural order of endogenous plants, usually with equitant leaves, and a rhizoma or cormus for their stem, but more particularly characterized by having three stamens, the anthers of which are turned outwards, and an inferior ovary. The genera are numerous, and some not well defined; they inhabit the temperate parts of the world in preference to the hottest, where they are comparatively rare. The Iris and Crocus are representatives of the predominant northern form of the order, as Gladiolus and Ixia are of the genera prevalent in the southern hemisphere. All the species are sufficiently ornamental to deserve cultivation, and many are of striking beauty.

Leaves and flowers of Sisyrinchium striatum. 1, the stamens; 2, the ripe fruit.

IRIDI'NA. [CONCHACEA, vol. vii., p. 426.]

IRI'DIUM, a metal discovered in 1803 by Mr. Tennant (*Phil. Trans.*, 1804), and also about the same time by Descotils in France. Its name was suggested from *Iris*, the rainbow, on account of the various colours assumed by the solution obtained with hydrochloric acid. When the grains of native platinum are digested in nascent chlorine (aqua regia), a black powder is left after the platinum has been dissolved, which consists chiefly of iridium and another peculiar metal, osmium [OSMIUM]; some ore of titanium and chromate of iron also occur in it. The iridium is obtained by fusing this black residue for at least an hour with twice its weight of hydrate of potash in a silver crucible; the residual matter is to be washed to remove the oxide of osmium, and the insoluble portion remaining is iridium, which has been oxidized during fusion, mixed with any insoluble impurity. This is to be digested in hydrochloric acid, and if free from iron the solution is blue; but it afterwards becomes of an olive green, and eventually it acquires a deep red tint.

When a plate of zinc is immersed in this solution of the chloride of iridium, or when it is decomposed by a very high heat, the metal is obtained of a whitish colour, and its specific gravity, as determined by Mr. Children, who fused it by his large voltaic apparatus, is above 18, while that of the native iridium found in minute grains in the Siberian platinum, according to Breithaupt, is 23·35. It is brittle, and when carefully polished has the appearance of platinum. When heated to redness in the air, if in a state of fine division (which is obtained by precipitation), it is oxidized, but not if in mass.

One of the most remarkable characters of iridium is the difficulty with which it is acted upon by acids. It is even questionable whether they act at all upon the perfectly pure metal; but when alloyed with platinum nascent chlorine dissolves a small portion of it.

Oxygen and Iridium combine and form several oxides: the protoxide, sesquioxide, and teroxide. They are precipitated by the alkalis from the corresponding chlorides, obtained as we shall presently state.

The protoxide of iridium is black, and greenish-grey when combined with water so as to form a hydrate. It is composed nearly of 1 equivalent of oxygen 8, and 1 equivalent of iridium 98, making 106.

The sesquioxide is also black, but its hydrate is deep brown. It is not decomposed by a low red heat, but at the temperature of melting silver it loses all its oxygen. When slightly heated with charcoal, sulphur, or phosphorus, it detonates violently: acids do not act upon it, but, on the contrary, it unites with salifiable bases. It is of course composed of about 1½ equivalent of oxygen 12, and 1 equivalent of iridium 98, making 110.

The teroxide of iridium is yellowish-brown, or greenish in the state of hydrate. The oxide, which gives a blue-coloured solution with hydrochloric acid, is suspected by Berzelius to be a compound of the sesquioxide and peroxide. It is obtained by adding ammonia to a solution of bichloride of iridium, and digesting the mixture with a gentle heat till the greater part of the ammonia is volatilized. It is then precipitated, combined with a little ammonia.

The binoxide has not been hitherto insulated. This great variety of oxides, and the facility with which they appear to pass from one into the other, account for the variety of tints which their solutions exhibit.

Chlorine and Iridium.—The protochloride of iridium is obtained by transmitting chlorine gas over pulverulent iridium heated to incipient redness: at a full red heat the chlorine is expelled. It is insoluble in water, and sparingly dissolved by acids or nascent chlorine; but when the hydrated protoxide is digested in hydrochloric acid a solution is obtained which appears to be the protochloride dissolved in hydrochloric acid.

It is composed of 1 equivalent of chlorine 36, and 1 equivalent of iridium 98, making 134.

Sesquichloride of iridium may be obtained by calcining iridium with nitre, digesting the product in nitric acid, and, after washing, by dissolving it in hydrochloric acid. This chloride has so dark a yellowish-brown tint, that a small quantity renders water opaque. It yields by evaporation a dark-coloured, uncrystallizable, deliquescent mass. It consists of 1½ equivalent of chlorine 54, and 1 equivalent of iridium 98, making 152.

Bichloride of iridium is formed by heating the sesquichloride in nascent chlorine. Like the preceding, it yields by evaporation a dark-coloured deliquescent mass, which at 104° loses chlorine and returns to the state of sesquichloride.

The terchloride of iridium has not been obtained in a separate state. It is of a rose-red tint.

Iridium combines with carbon when a piece of this metal is held in the flame of a spirit lamp. The resulting compound consists of about 19·8 of carbon, and 80·2 of iridium.

No other compounds of iridium are much known: it has however been inferred, from the colour of the precipitates formed by the addition of hydrosulphuric acid to the preceding chlorides, that there are corresponding sulphurets.

IRIS. [EYE; RAINBOW.]

IRITIS is an inflammation of the iris, the membrane that surrounds the pupil of the eye. [EYE.] It most frequently originates in a disordered state of the system, as in gout or syphilis, but it sometimes follows the exposure of the eye to an intense light, or is produced by external injury, as the wound which is made in the operation for cataract, &c.

Iritis is principally characterized by an effusion of lymph, both into the substance of the membrane, producing a peculiar dullness of its colour, and on its surface in the form of small masses which adhere at the edge of and around the pupil. The eye is at the same time irritable to light, and the pupil is closely contracted; there is redness of the conjunctiva, and a zone of a bright pink colour is usually seen surrounding the margin of the cornea.

Iritis is very likely to end in adhesions of the iris to the adjacent parts, by the lymph which is deposited upon it becoming organized, and having its vessels united with theirs; in which case, irregularity in the form of the pupil, a loss of its power of contracting and dilating, or even its complete closure and obliteration, with corresponding degrees of obscurity of vision or total blindness, may ensue. These results may be produced in a few days; and the treatment must therefore be prompt and vigorous. Blood must be freely and sometimes repeatedly drawn from the arm, or by cupping and leeches from the head or neck; mercury must be administered in frequent and full doses till salivation is produced, and belladonna should be applied to or around the eye, to produce dilatation of the pupil and thus prevent its being closed.

IRKUTSK. [SIBERIA.]

IRON. Of all the metals iron is the most widely diffused, the most abundant, and the most useful. It is found not only intermixed with soils, and contained in rocks and minerals, but it is even met with in some animal and vegetable bodies, and also in mineral waters.

Iron occurs rarely, if indeed at all, in nature in the metallic state, for almost the whole of it that has been found occurs as meteoric iron containing nickel, or in meteoric stones. It has however been stated that it has been discovered *in situ* near Canaan in the United States; it there occurs in a vein, two inches wide, in chlorite schist, filled with native iron. It appears that this iron is traversed by graphite. Its specific gravity is 5·95 to 6·71. The Uralian Mountains yield a kind of native iron which is accompanied with platinum.

The greatest quantity of iron is found either combined with oxygen, oxygen and carbonic acid, or with sulphur; the last mentioned is not however worked as an ore. The best iron ores are oxides, which occur in primitive countries, where they generally form very large beds; such are those o Sweden: but the greater part of the iron ore of Britain is an impure carbonate.

The properties of iron are, that it is greyish-white with a tint of blue; it is extremely ductile, so that it may be drawn into wire finer than the human hair, but it cannot be beaten into very thin leaves. It is of all metals the most tenacious, for a wire 0·787 of a line in diameter is capable of supporting a weight of about 550 lbs.

Iron is susceptible of a high polish. It is combustible when minutely divided, as in the state of filings, which is shown by sprinkling them in the flame of a spirit lamp. It is very hard at common temperatures, and this property may be increased by its being heated and then suddenly cooled; it then however becomes brittle. It requires a most intense heat to melt it, but when heated to redness it becomes soft and pliable, and possesses the valuable property of *welding*, that is, two pieces of red-hot iron may be made to unite by hammering. Its texture is fibrous. Its specific gravity is about 7·77, but this varies in some degree according to the extent to which it has been drawn, rolled, or hammered, and it is increased by fusion. Iron, or rather steel, is capable of being rendered permanently magnetic, a property which no other metal possesses but nickel: when heated to redness this property is lost, and a loadstone suffers the same loss just below visible ignition; while a steel magnet loses its polarity when subjected to the temperature of boiling almond oil. Iron has great affinity for oxygen and sulphur, and some other elementary bodies, and combines with them in various proportions.

Having now stated the general properties of this metal, we proceed to describe those compounds which occur naturally containing the largest quantity of it, and among these are of course the various ores of this metal: and we shall prefix a short account of the more remarkable masses which have occurred of

Meteoric Iron.—There have been found in different parts of the earth large masses of native or metallic iron, of the

history and origin of which nothing very accurate is known; but they are regarded as being of meteoric origin, for it is invariably found that, like the iron which occurs in meteoric stones, this metallic iron contains nickel, and no such compound or mixture is found in the earth in veins or beds: and in point of fact two masses of such iron were seen to fall at Hradschina, near Agram in Croatia, in 1751. It contained 3·5 per cent. of nickel. Similar masses have been found in Africa, America, and Siberia; that in the last-mentioned part of the world was discovered by Professor Pallas: it weighed 1600 lbs., had a cellular structure, and contained crystals and grains of a green substance of a vitreous appearance, which have been stated to be olivine. This iron contains only 1·5 per cent. of nickel. One of the largest masses is that found in Peru by Don Rubin de Celis; it weighed 15 tons, and contained nickel. This was also the case with the knives which Captain Parry obtained from the Esquimaux. The largest quantity of nickel contained in any specimen was about 10 per cent.

Meteoric iron sometimes occurs crystallized; the primary form is the cube, and it is stated to have been found in regular octohedrons. It has no apparent cleavage. Fracture hackly; hardness 4·5; specific gravity 6·48 to 7·768; opaque; lustre metallic; colour pale steel grey.

OXIDES OF IRON.—The protoxide of iron does not occur in nature, except in combination, and usually with carbonic acid: that which most nearly approaches it is

Magnetic Iron, sometimes called *oxydulous iron* and *octohedral iron*. This ore is found crystalline, massive, and arenaceous. The crystals occur attached and imbedded. The primary form is a cube, but it is generally met with in the form of the regular octohedron. Cleavage parallel to the planes of the octohedron, but not obtainable in some varieties. Fracture uneven or conchoidal; hardness 5·5 to 6·5; scratches fluor-spar, and is scratched by quartz; specific gravity variously stated from 4·4 to 5·094; opaque; lustre metallic, occasionally bright; colour iron or steel grey; streak black; obeys the magnet.

Massive Varieties amorphous; structure granular to compact. It is of this variety of iron ore that native loadstones consist. This ore occurs in various parts of the world, especially in the North of Europe, and it is of it that the best Swedish iron is made, and so also is the iron which yields the wootz steel of the East Indies. It is generally found in primitive countries. This ore frequently contains titanium; but the varieties have not been well distinguished. By the blowpipe it becomes brown, and loses its magnetic property, but does not fuse.

It consists of 28·4 of oxygen and 71·6 of iron, which are equal to

Two equivalents of sesquioxide of iron	80
One equivalent of protoxide of iron	36

There are several ores, which possess very different appearances, that are altogether composed of the sesquioxide or peroxide of iron, and which are principally the *oligiste iron ore* and the *hematite*.

Oligiste Iron; Specular or Micaceous Iron.—This occurs crystallized and massive. The crystals are attached; the primary form is a rhomboid. Cleavage parallel to the primary planes and perpendicular to the axis in some varieties; fracture uneven, conchoidal; hardness 5·5 to 6·5; scratches phosphate of lime; is scratched by quartz; specific gravity 5·0 to 5·25; lustre metallic; colour steel and iron grey; the surface frequently iridescent; obeys the magnet slightly; streak red and reddish-brown.

It is found in the island of Elba and in many other parts of Europe. It also occurs in the lava of Auvergne in France, and in that of Vesuvius.

Goethite, Pyrosiderite.—Occurs in very thin transparent crystalline plates in the cavities of black hematite. Colour brownish red, by reflexion yellowish, in a strong light of a brilliant red; lustre adamantine. It occurs in England and in Germany. The former yielded by analysis

Peroxide of iron	89·2
Water	10·8
	100·

Iron Froth consists of very thin brownish red scaly particles, which have a greasy feel, and stain the fingers. It is found plentifully in Devonshire and Lancashire, and was ascertained by Dr. Henry to be pure peroxide of iron. The massive varieties are amorphous; structure foliated.

Red Hematite occurs in globular and botryoidal masses. Structure fibrous, radiating, opaque. Specific gravity 4·7 to 5. Lustre externally, sometimes metallic, sometimes dull; internally, nearly dull. Colour externally red; greyish red, &c., internally, and streak red. It occurs in large quantity at Ulverstone in Lancashire, and in other parts of Great Britain and Europe. According to D'Aubuisson it consists of

Peroxide of iron	94
Silica	2
Lime	1
Water	3
	100

Brown Hematite; Hydrous Oxide of Iron; Brown Iron Ore.—Occurs in attached crystals and massive prisms. Primary form a right rhombic prism. Cleavage parallel to the short diagonal; fracture uncertain. Hardness 5·0 to 5·5. Specific gravity 3·93; lustre adamantine; nearly opaque; translucent. Colour brown of various shades. Streak yellowish brown. Occurs in Cornwall.

Massive Varieties.—Globular, reniform, and some of the varieties of brown and yellow clay iron-stone. Stalactitic, structure fibrous, or fibro-laminar. Sometimes occurs in pseudomorphous crystals. It occurs in most parts of the world. Analysis by D'Aubuisson:—

	Fibrous.	Compact.
Peroxide of iron	82	84
Water	14	1
Oxide of manganese	2	2
Silica	1	2
	99	89

Carbonate of Iron; Brown Spar; Spathose Iron Ore.—This occurs in attached crystals and massive. Primary form a rhomboid. Cleavage parallel to the primary planes, distinct. Fracture imperfect conchoidal; hardness 3·5, 4·5; specific gravity 3·6 to 3·829; transparent, translucent, opaque; lustre vitreous, inclining to pearly; colour white, yellow, red, and brown of different shades.

Massive Varieties: tabular, structure fibrous; botryoidal and globular (these being called *sphærosiderit*), structure fibrous, diverging; amorphous, structure foliated, granular, compact. Found in Cornwall, Scotland, and Ireland, and in other parts of Europe; and also in America.

Before the blowpipe it blackens and becomes magnetic, but does not fuse; in the reducing flame it colours borax bottle-green, and in the oxidating yellow; dissolves in acids with effervescence. Analysis, by Beudant, of the hexahedral variety:—

Carbonic acid	38·72
Protoxide of iron	59·97
Oxide of manganese	0·39
Lime	0·92
	100·

Clay Iron-Stone, or *Argillaceous Iron Ore*, consists essentially of carbonate of iron mixed with various proportions of earthy matter; on an average carbonate of iron forms about one-third of the abundant clay iron-stone of England, Wales, and Scotland. It occurs in beds and in coal deposits; it is found sometimes in globular masses, and also columnar.

Although various other minerals occur containing large quantities of iron, yet the above-described contain almost all the ores which are extensively used in the manufacture of iron. Other ferruginous compounds have been already described under arbitrary names, and others still remain to be noticed in alphabetical order.

Carburet of Iron; Graphite. [ANTHRACITE.]

Sulphur and Iron exist in combination in enormous quantities; the compounds which it forms are called *magnetic iron pyrites*, *iron pyrites*, and *white iron pyrites*.

Magnetic Iron Pyrites, Protosulphuret of Iron, occurs in embedded hexagonal crystals and massive; primary form a rhomboid; cleavage parallel to all the planes of a regular hexagonal prism; fracture uneven, sometimes conchoidal; hardness 3·5 to 4·5; scratches calcareous spar, and is scratched by felspar; specific gravity 4·63; opaque; lustre metallic; colour bronze yellow mixed with red; streak greyish black; obeys the magnet but feebly; soluble in dilute sulphuric acid; when exposed to the blowpipe on charcoal is converted into oxide of iron; occurs at Kongsberg in Norway and Andreasberg in the Hartz. Analysis by Hatchett:—

Sulphur	36·5
Iron	63·5
	100·

Massive Varieties amorphous; structure foliated, granular, compact; found in Cornwall, Wales, Germany, North America, &c.

Iron Pyrites; Martial Pyrites; Persulphuret, or bisulphuret, of Iron.—Occurs in attached and imbedded crystals, and massive; primary form a cube; cleavage parallel to the primary planes, distinct; less so parallel to the planes of the octohedron; fracture uneven, sometimes conchoidal; hardness 6·0 to 6·5; scratches felspar, and is scratched by quartz; colour brass-yellow; streak brownish-black; lustre metallic opaque.

Massive Varieties: amorphous, structure granular, compact; globular and stalactitic, structure fibrous or columnar, radiating; surface frequently reddish brown, owing to the loss of sulphur and acquisition of oxygen. It sometimes contains gold; the pyrites of Anglesey, Sweden, and Bohemia contains selenium.

By the blowpipe sulphur is expelled and magnetic oxide of iron remains. It is scarcely acted upon by dilute sulphuric acid, but nitric acid dissolves iron and deposits sulphur. Analysis by Hatchett:—

Sulphur	52·15
Iron	47·85
	100·

Iron pyrites occurs abundantly in every part of the world. It is frequently found in the form of various fruits. The amorphous occurs sometimes to a great extent in coal-beds. Very large crystals occur in Cornwall and South America. The massive varieties in general more readily become oxidized and converted into sulphate of iron than the crystallized, and hence it is largely employed in preparing copperas.

White Iron Pyrites occurs in attached crystals and massive. Primary form a right rhombic prism; cleavage parallel to the planes of the primary form; fracture uneven, granular; hardness 6·0 to 6·5; scratches felspar, is scratched by quartz; colour various shades of yellowish, greenish, and greyish-white; streak greyish-black; opaque; lustre metallic.

Massive Varieties, botryoidal, reniform, stalactitic, and amorphous. Structure diverging, fibrous, or columnar. It is found in Cornwall, Derbyshire, Bohemia, and various other mining districts. According to Berzelius it consists of

Sulphur	53·35
Iron	45·07
Manganese	0·70
Silica	0·80
	99·92

Having now mentioned those ores and compounds which contain most iron, we refer to ASSAYING for the means by which their value is determined. We now proceed to consider the artificial oxides and other compounds of iron which are procured by chemical agency.

Oxygen and Iron do not combine at common temperatures when both are quite free from moisture, but when filings moistened with a little water are exposed to the air, a black powder is formed by the absorption of oxygen, which is almost entirely protoxide of iron, and was formerly employed in medicine under the name of *martial æthiops*. Protoxide of iron, nearly pure, may also be procured by dissolving iron in dilute sulphuric acid, decomposing the solution by potash and drying the precipitate out of the contact of air.

The properties of this oxide are, that it is black, tasteless, insoluble in water, readily dissolved by most acids, and obeys the magnet. It is precipitated from its saline solutions by potash and ammonia in the state of white hydrate; tincture of galls and hydrosulphuric acid do not produce any alteration in its solutions; by the alcaline carbonates protoxide of iron is thrown down as a white carbonate, and by ferrocyanide of potassium as a colourless compound, which speedily becomes Prussian blue when exposed to the air. It is composed of

One equivalent of oxygen	8
One equivalent of iron	28
Equivalent	36

Magnetic Oxide of Iron.—This is the ore already described as crystallizing in octahedrons; it is obtained artificially by passing water over ignited iron in a porcelain tube; it is also formed when iron is heated in the open air, and the scales which fall from iron when it is rolled hot consist principally of this oxide. It is black, obeys the magnet, brittle, easily reduced to powder, insoluble in water, and by sulphuric acid is dissolved and separated into protoxide and sesquioxide; the solution is in fact a mixture of protosulphate and persulphate of iron. It gives a black precipitate with tincture of galls, and a blue one with ferrocyanide of potassium. It is composed of one equivalent of protoxide 36, and 2 equivalents of peroxide 80; or it may be regarded as constituted of

Four equivalents of oxygen	32
Three equivalents of iron	84
Equivalent	116

It is sometimes described as a $\frac{4}{3}$ oxide of iron.

Peroxide, or Sesquioxide, of Iron.—Various ores, among others hematite, have been described as consisting of this oxide, which is, in fact, common rust of iron, and it is obtained by the action of a plate of iron upon moist atmospheric air. It may be easily procured also by acting upon iron filings with nitric acid; when the acid is moderately strong, but little iron is dissolved, the whole being at once precipitated in the state of red peroxide. When more dilute, a solution of pernitrate is obtained, from which the alkalis precipitate peroxide, and ferrocyanide of potassium Prussian blue. Like hematite, this artificial oxide has a red colour; it is inodorous, insipid, insoluble in water, forms red solutions with acids, but does not readily dissolve in them when it has been heated. It is composed of—

One and a half equivalent of oxygen	12
One equivalent of iron	28
Equivalent	40

Chlorine and Iron combine to form two chlorides, the protochloride and the perchloride. The protochloride may be formed by passing dry hydrochloric acid gas over iron heated to redness in a porcelain tube; hydrogen gas is evolved, and the surface of the iron is covered with a white crystalline protochloride, which, if the temperature be much increased, sublimes. Or it may be prepared by dissolving the metal in hydrochloric acid, and evaporating the solution to dryness out of the contact of air. In this case also the hydrogen of the decomposed hydrochloric acid is evolved; the protochloride thus obtained is grey and crystalline.

This compound is very soluble in water, but insoluble in absolute alcohol; the solution by exposure to the air absorbs oxygen, sesquioxide of iron is precipitated, and sesquichloride of iron of a yellowish colour remains in solution. This salt is also decomposed by oxygen at a high temperature, chlorine being evolved and oxide of iron formed.

When the solution is carefully evaporated, rhombic crystals, which, like it, are of a green colour, are formed; they contain water and deliquesce by exposure to the air. The solution of protochloride of iron (frequently called protomuriate) dissolves nitrous oxide gas, and the solution has been used in eudiometry, for the purpose of absorbing uncombined oxygen gas. [EUDIOMETER.] It is decomposed by the alkalis, which throw down protohydrate of iron, and by their carbonates, which yield protocarbonates. It gives no precipitate with hydrosulphuric acid or tincture of galls, and a white one with ferrocyanide of potassium, which speedily becomes blue.

It is composed of—

One equivalent of chlorine	36
One equivalent of iron	28
Equivalent	64

Sesquichloride, or Perchloride, of Iron may also be prepared by two processes: first, by heating iron wire in dry chlorine gas; combustion attended with a red light ensues, and a compound is formed, volatile at a heat below redness, and which exists in the form of brownish iridescent scales. This salt is very deliquescent, and dissolves readily in water, alcohol, and æther, and the solutions have a yellow colour.

The second method of obtaining sesquichloride of iron is that of dissolving the sesquioxide in hydrochloric acid: a

reddish solution is formed, which, by evaporation till it becomes of the consistence of a syrup, yields reddish-brown crystals, which are very deliquescent and soluble. The aqueous solution of sesquichloride of iron is decomposed by the alkalis, yielding a precipitate of hydrated sesquioxide of iron. The carbonates produce the same effect, for sesquioxide of iron does not unite with carbonic acid. Tincture of galls gives, with the solution of this salt, a deep black precipitate, and ferrocyanide of potassium a deep blue precipitate, which is Prussian blue. It is sometimes called permuriate of iron.

Sesquichloride of iron is composed of—

One and a half equivalent of chlorine .	54
One equivalent of iron	28
Equivalent	82

Azote and hydrogen do not form any compound with iron, or at any rate no permanent compound, though it seems probable that nascent hydrogen volatilizes, if it does not unite with, a small portion of this metal, when used for preparing the gas by solution in an acid.

Fluorine and Iron.—The protofluoride may be formed by dissolving iron in a solution of hydrofluoric acid; small colourless square crystals are obtained, which are sparingly soluble in water, and become of a pale yellow colour by the action of the air. When heated they lose water, and may then be heated to redness without expelling the fluorine.

It is composed of—

One equivalent of fluorine . . .	18
One equivalent of iron	28
Equivalent	46

The perfluoride, or sesquifluoride, of iron is procured by dissolving recently precipitated sesquioxide in hydrofluoric acid; the solution is colourless. By evaporation a pale flesh-coloured substance is left, which has a somewhat astringent taste and is but sparingly dissolved by water.

It consists of—

One and a half equivalent of fluorine	27
One equivalent of iron	28
Equivalent	55

Bromine and Iron.—When the vapour of bromine is passed over red-hot iron wire, a yellow fusible bromide is formed, which is readily soluble in water. When also bromine mixed with water is made to act upon iron, a solution of the protobromide, of a greenish colour, is obtained.

It consists of—

One equivalent of bromine . . .	78
One equivalent of iron	28
Equivalent	106

A perbromide may also be formed. But these compounds are not important.

Carbon and Iron combine, and the resulting compound is steel, or perhaps it may be stated that steel contains carburet of iron. [STEEL.] By the long fusion of steel with charcoal, Stodart and Faraday obtained a highly crystalline compound, containing from 5 to 6 per cent. of carbon, whereas steel usually contains only from 1·3 to 1·78 per cent. When Prussian blue is decomposed without the access of air at a red heat, a carburet of iron remains, composed of one and a half equivalent of carbon and one of iron; it is a black pulverulent substance, which at a low heat takes fire in the air, when carbonic acid is given out, and sesquioxide of iron left.

The substances called graphite, plumbago, or black-lead, have been regarded as carburets of iron; it is however more than questionable whether the small and uncertain portion of iron which they contain is not in a state of mixture rather than combination.

Sulphur and Iron readily unite, and the native compounds have been already mentioned. Protosulphuret of iron, having much the appearance of the native mineral, may be formed by heating iron to whiteness and rubbing a mass of sulphur upon it. The sulphuret formed readily fuses, and should be dropped into water, removed from it, and dried. It may also be formed by other processes, as by adding a hydrosulphate to protochloride or protosulphate of iron. That made by the first process is of a bronze colour, moderately hard and brittle; that formed by the last is dark and pulverulent. When put into diluted sulphuric or hydrochloric acid, sulphuretted hydrogen gas is evolved, and a protosulphate or protochloride of iron formed. It is a very useful substance for the preparation of hydrosulphuric acid gas, by the action of these acids.

It is composed of—

One equivalent of sulphur . . .	16
One equivalent of iron	28
Equivalent	44

Bisulphuret, or Persulphuret, of Iron has been occasionally formed, both in the moist and dry way, artificially: fine yellow and well defined cubic crystals have been accidentally obtained during the preparation of hydrochlorate of ammonia from ammoniacal gas liquor. According to Berzelius, it may also be formed by cautiously heating the artificial protosulphuret with as much sulphur as it already contains; by this there is formed a bulky powder of a yellow colour and metallic appearance; it is not attracted by the magnet, nor does hydrochloric or sulphuric acid act upon it.

It is composed of—

Two equivalents of sulphur . . .	32
One equivalent of iron	28
Equivalent	60

Some other sulphurets of iron may be also artificially formed, but they are not of any great importance.

Phosphorus and Iron.—Diphosphuret of iron may be formed by several processes; the direct one is that of dropping phosphorus into a crucible containing red-hot iron wire; it is also obtained where the protophosphate of iron is heated with a charcoal-lined crucible; phosphorus and oxygen being expelled. It is a fused granular mass, having the colour and lustre of iron, is very brittle, and not acted upon by hydrochloric acid. It is said that what is called cold-short iron owes its brittle property to the presence of this compound.

It is composed of—

One equivalent of phosphorus . .	16
Two equivalents of iron	56
Equivalent	72

The perphosphuret of iron is obtained by the action of phosphorus on persulphuret of iron at a moderate heat, it resembles the diphosphuret in its properties.

It consists of—

Four equivalents of phosphorus . .	64
Three equivalents of iron . . .	84
Equivalent	148

Iodine and Iron.—When iron-filings are digested in a mixture of water and iodine, the metal is dissolved, and a green solution is obtained, which by evaporation yields green tabular crystals of protiodide of iron; these when fused leave an iron-grey coloured opaque mass, which is very deliquescent, and soluble both in water and in alcohol. The solution rapidly absorbs oxygen, and peroxide of iron is precipitated, unless an iron wire be kept in it. It is used in medicine.

It is formed of—

One equivalent of iodine . . .	126
One " iron	28
Equivalent	154

Periodide, or sesquiodide, of iron is formed by digesting iron with excess of iodine, and subliming the product. It is a red volatile compound deliquescent, and soluble in water and in alcohol.

It is composed of—

One and a half equivalent of iodine	189
One equivalent of iron . . .	28
Equivalent	217

Boron and Iron are made to combine with difficulty in any notable proportion. When hydrogen gas is passed over borate of iron heated to redness in a porcelain tube, there was obtained, according to Lassaigne, a boruret of iron consisting of 22·57 boron and 77·43 iron. It was of a silver-white colour and very brilliant; it was with difficulty acted upon by sulphuric or hydrochloric acid, because the boron set free enveloped the metal and prevented their action.

Selenium and Iron may be made to combine by heating filings of the metal with selenium. The seleniuret has a greyish colour with a tint of yellow; it is hard, brittle, and when heated by the blowpipe loses selenium; it is

decomposed by hydrochloric acid when heated, and the results are seleniuretted hydrogen and protochloride of iron.

It is composed of—

One equivalent of selenium . .	40
One „ iron	28
Equivalent	68

Having now described the more important compounds which iron forms with the elementary gases and non-metallic solids, we shall briefly describe some of its alloys, and then mention such salts as its oxides form with acids as are most useful and best known.

The Alloys of Iron are much less useful than might be expected from the extreme utility of the metal itself.

Potassium and iron, and sodium and iron, combine when heat is applied to them: the alloys are more fusible than pure iron, especially when in contact with the air. These alloys are decomposed by air and water. When a mixture of magnesia, iron filings, and charcoal is exposed to the melting heat of iron, the resulting globule contains traces of magnesium. With lime no analogous effect is produced.

Silicium and iron combine readily when silica is fused with iron filings and charcoal in powder. The compound is ductile or brittle according to the quantity of charcoal which it contains. Silicium does not appear to diminish the ductility of iron, nor does the alloy alter by exposure to the air when the silicium does not exceed 5 or 6 per cent. Iron combines also with aluminum and glucinum.

Arsenic combined with iron and with sulphur occurs as a mineral body. This contains nearly one-fifth of its weight of sulphur. In Silesia however an arseniuret of iron occurs, which consists of 65·88 arsenic, 32·25 iron, and 1·77 sulphur. This last may therefore be considered as accidental admixture. It is used for preparing arsenious acid and realgar.

An alloy of one part of arsenic and two parts of iron is obtained by heating in a covered crucible, until fused, a mixture of one part of iron filings and a little more than half a part of arsenic. It has a greyish-white colour, does not obey the magnet, is very brittle, and much more fusible than iron. When heated in the air the arsenic is converted into arsenious acid and volatilized, and oxide of iron is left. An alloy containing only one-fifth of arsenic obeys the magnet.

Chromium and iron may be combined. This alloy is but little known. With columbium iron forms an alloy hard enough to scratch glass. It is not at all ductile, is very difficult to break, and gives a brown powder. Acids dissolve the iron, leaving pulverulent metallic columbium.

Titanium does not appear to be susceptible of combination with iron. Zinc is with difficulty made to unite with iron, but yet in some operations a compound of these metals has been formed, the zinc constituting however much the larger portion. The alloy is white, has a metallic appearance, and is brittle. It has been proposed to cover iron with zinc, in the same way as with tin, to prevent oxidizement. As yet however it has not been rendered practically useful.

Tin and iron combine in tin plates, which are plates of iron, both sides of which are alloyed or combined with tin. According also to Bergman, when a mixture of tin and iron is fused, two separate layers are formed, each constituting a peculiar alloy of tin and iron: one of them, consisting of one part of iron and twenty parts of tin, is ductile, of a rather deeper colour than tin, and somewhat harder; whilst the other, composed of two parts of iron and one part of tin, is rather ductile, but so hard that it cannot be cut with the knife.

Antimony and iron unite when heated together in close vessels: the alloy is white, hard, brittle, and its specific gravity is less than that of the mean of the two metals. No metal appears to deprive iron more of its magnetic property than antimony.

No compound of tellurium and iron has yet been examined.

Cobalt and iron combine by fusion: the alloy is hard and magnetic.

Nickel and iron unite easily. It has already been mentioned that meteoric iron contains from about 2 to 10 per cent. of nickel. The artificial alloy is less liable to rust than iron alone; but when the nickel amounts to about 10 per cent. the ductility of the iron begins to diminish.

Bismuth combines with iron, but with difficulty; a very small portion of iron renders the alloy magnetic.

Molybden forms a bluish-grey brittle compound with iron. Equal parts of these metals may be fused by the blowpipe, but one part of iron and two parts of molybden form a bright grey compound, which is infusible by the blowpipe, attracted by the magnet, and of a fine grained fracture.

Copper is with difficulty combined with iron. The alloy is magnetic, even when it contains only one-tenth of iron. It is stated that iron which contains copper is rendered more tenacious, and does not become brittle till near a red heat.

Silver combines readily with iron when they are fused together, but they separate on solidification, and globules of silver appear on the surface of the alloy. When even the quantity of iron does not exceed 1-400th, it may be perceived that it is not combined but intermixed with the iron.

Mercury and iron do not unite directly. The addition of another metal favours the amalgamation. An amalgam may be obtained by digesting tinned plate in boiling mercury. The alloy is silvery-white, tenacious, almost ductile, and obeys the magnet. Other processes have also been proposed.

Lead and iron combine with difficulty. If a mixture of the two metals be fused, there are obtained two layers of alloy; the upper one is iron containing a little lead, and the lower one lead containing a little iron.

Rhodium and iridium may both be combined with iron and also with steel. [Steel.] Iron also unites with tungsten: the alloy is of a bright brown colour, hard, harsh to the touch, and brittle.

Gold and iron combine with facility. A compound of eleven parts of gold and one part of iron is nearly white. It is very ductile, and its specific gravity 16·885. An alloy of three parts of iron and one part of gold is of a silver colour, and is attracted by the magnet. Steel may be soldered with gold.

Iron and platinum, in equal quantities, form an alloy which is susceptible of a fine polish, and does not tarnish in the air. The colour of this compound is such as to render it very useful for reflectors. Its specific gravity is 9·862. Platinum may also be combined with steel. [Steel.]

Having described the more important binary compounds of iron, we shall consider those which its oxides form with some acids, and also notice some combinations which are not included in this class.

The action of acids upon iron is different, being greatly dependent upon their nature and composition. An aqueous solution of sulphurous acid dissolves the metal without the evolution of any gas whatever, and a solution of the protoxide is obtained; concentrated sulphuric acid, when cold, scarcely acts upon iron, but when they are heated the sulphuric acid is decomposed, sulphurous acid is evolved, and oxide of iron is formed; dilute the sulphuric acid, and then the water is decomposed, hydrogen gas is given out, and sulphate of protoxide of iron is formed. When iron is put into liquid hydrochloric acid, hydrogen gas is then also evolved, but this is derived from the decomposition of the acid, and not of the water, and the metal unites with the chlorine to form a protochloride. Nitric acid when concentrated has no action upon iron, whether cold or hot; but when diluted, nitric oxide is evolved, owing to the decomposition of the acid, and protoxide or peroxide of iron is formed, according to the degree to which the acid is diluted.

The first salt which we shall describe is the

Sulphate of Iron, or *Sulphate of Protoxide of Iron*. It is largely prepared for various purposes, especially for dyeing black, by exposing iron pyrites to the action of air and moisture, in masses which are called *copperas beds*. By absorbing oxygen, the sulphur becomes sulphuric acid, and the iron protoxide, and these combining form protosulphate of iron; as however there is great excess of sulphuric acid, pieces of old iron are added to saturate it, and the copperas, or green vitriol, is obtained in the state of crystals, by evaporating the solution.

For nicer purposes, especially for medicinal use, sulphate of iron is prepared by dissolving iron filings or turnings in dilute sulphuric acid; it may also be obtained by dissolving protoxide or protocarbonate of iron. The solution is of a bluish-green colour, and the salt obtained has the following properties: the primary form of the crystal is an oblique rhombic prism; its colour is bluish-green when recently

prepared, but by exposure to the air, and the partial peroxidizement of the iron, it becomes first green and eventually yellowish. Like the other salts of iron, it has a disagreeable styptic taste; two parts of cold water, and three-fourths of a part of boiling water, dissolve one part of this salt; when moderately heated it loses the greater part of its water and becomes white, and when subjected to a red heat it is partly converted into persulphate and partly into peroxide of iron; and when the heat is long continued, totally into peroxide; but when subjected to distillation without the free contact of air, it yields a peculiar kind of sulphuric acid. This salt is insoluble in alcohol; the aqueous solution is decomposed by the alkalis, which precipitate hydrated protoxide of iron; by the alkaline carbonates, which throw down protocarbonate of iron; and by ferrocyanide of potassium, which, when the solution is quite free from peroxide, gives a white precipitate, but if any peroxide be present, which is generally the case, then the colour of the precipitate is more or less blue, dependent upon its quantity; tincture of galls also gives no precipitate in a solution of perfect protosulphate of iron, but, for the reason already stated, it generally gives more or less of a dark-coloured precipitate. The aqueous solution, when exposed to the air, owing to the peroxidizement of the iron, gradually lets fall a precipitate which is a subpersulphate of iron. The solution also absorbs nitric oxide, and hence is used in eudiometrical processes. [EUDIOMETER.]

Sulphate of iron is composed of—

One equivalent of sulphuric acid .	40
One equivalent of protoxide of iron	36
Seven equivalents of water . .	63
Equivalent	139

We have given a rather detailed account of the properties of this salt, because it may be considered as a type of the soluble salts of protoxide of iron, and will save useless repetition.

Sulphate of Peroxide of Iron, or *Sesquipersulphate of Iron*, may be considered as representing the soluble salts of peroxide of this metal. It may be prepared by dissolving the moist peroxide, obtained by decomposing the solution of the perchloride with an alkali, in dilute sulphuric acid; but it is generally formed by heating a solution of the protosulphate with nitric acid, which being decomposed yields oxygen to the protoxide and converts it into peroxide. This solution is of a reddish colour when concentrated, and yellowish when diluted. No crystals are obtained by evaporation, but there remains a brown deliquescent mass; its taste is very astringent, and it is soluble in alcohol; when concentrated sulphuric acid is added to a strong solution of this salt, it is precipitated in the state of a white anhydrous powder. The solution, like that of the other persalts of iron, gives a yellow precipitate of hydrated peroxide with the alkalis, an intense blue one with ferrocyanide of potassium, and a very dark one with tincture of galls. It is decomposed by heat, which expels the sulphuric acid, and leaves peroxide of iron. This salt exists in what are termed the *mother waters* of the copperas-makers, and it is also formed, though very slowly, by the action of the air upon a solution of the protosulphate of iron· a subpersulphate being precipitated.

It is a sesquisalt, composed of—

One equivalent and a half of sulphuric acid .	60
One equivalent of sesquioxide, or peroxide .	40
Equivalent	100

Nitrates of Iron. Of these, as of the sulphates, there are two. When iron is acted upon by very dilute nitric acid, a protonitrate of a pale green colour is obtained; but when the acid is moderately diluted pernitrate of iron is formed: this resembles the persulphate in its more important properties, and is, like it, a sesquisalt.

Carbonate of Iron. It is only the protoxide of iron which combines with carbonic acid to form a solid compound. It has already been mentioned that carbonate of iron exists in nature, and is the basis of what is termed the *argillaceous iron ore;* it sometimes also occurs pure in transparent rhombic crystals, much resembling calcareous spar in appearance. The crystals are however more commonly yellowish-brown, and constituting what is called *spathose iron ore.* Carbonate of iron is precipitated from the solution of the protosulphate by the alkaline carbonates; but on account of the facility with which the protoxide absorbs oxygen, it is almost impossible to obtain it perfect, in a dry state. Carbonate of iron is decomposed by heat and by acids, which expel the carbonic acid. Carbonate of iron, held in solution by excess of carbonic acid, exists in chalybeate waters.

It is composed of—

One equivalent of carbonic acid .	22
One equivalent of protoxide of iron	36
Equivalent	58

Phosphates of Iron. The protophosphate occurs in Cornwall, America, &c. It is sometimes called *Vivianite.* The primary form of the crystal is an oblique rhombic prism. Cleavage parallel to the oblique diagonal; fracture indistinct; hardness 1·5 to 2·0; colour various shades of blue and green; streak lighter than colour; lustre vitreous; translucent; transparent; specific gravity 2·6 to 2·7. Soluble in dilute sulphuric and nitric acids without effervescence. Before the blowpipe on charcoal intumesces, reddens, and melts into a steel-grey globule with metallic lustre. *Massive varieties,* aggregations of crystalline particles, or globular and amorphous earthy masses.

Analysis of the crystallized (No. 1) by Stromeyer, and of the earthy (No. 2) by Klaproth:—

	No. 1.	No. 2.
Phosphoric acid .	31·18	47·5
Protoxide of iron .	41·23	32·
Water . . .	27·49	20·
	99·90	99·5

This compound may be formed artificially by adding a solution of phosphate of soda to one of protosulphate of iron; the precipitate is at first blue, but by attracting oxygen from the air it is converted into perphosphate, and then becomes white. It is soluble in most acids, and may be precipitated from them by ammonia without being decomposed.

Perphosphate of Iron is white; it is obtained by adding phosphate of soda to persulphate of iron. Like the protophosphate, it is insoluble in water, but dissolved by acids, and may be precipitated from them unaltered.

Arseniates of Iron. [ARSENICAL MINERALS.] The protoarseniate of iron is obtained by adding arseniate of potash to a solution of protosulphate of iron; a greyish precipitate of protoarseniate is obtained, which by exposure to the air absorbs oxygen and becomes darker. The perarseniate of iron is obtained by precipitating a solution of the persulphate by arseniate of potash. It is a yellowish-white insoluble powder.

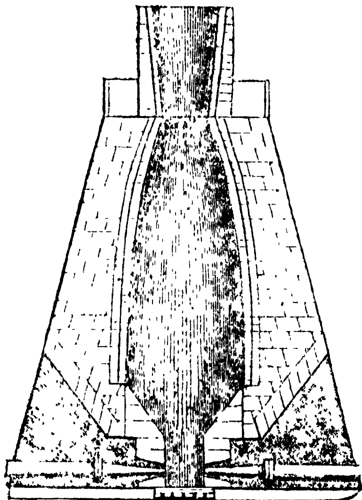
Chromate of Iron. [CHROMIUM.]

Tungstate of Iron. [TUNGSTEN.]

Percyanide of Iron. Prussian Blue. [BLUE.]

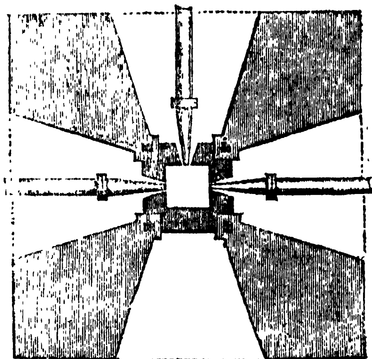
We shall conclude this part of the subject with a brief account of the

General properties of the Salts of Iron. Those salts which contain or yield the protoxide are distinguished by the following properties:—They give no precipitate with tincture of galls or hydrosulphuric acid; a white one, which becomes speedily blue on exposure to the air, with ferrocyanide of potassium, and a blue one with the sesquiferrocyanide. Solution of chloride of gold, and especially of the sodium chloride, gives a dark-coloured precipitate, and when nitrate of silver is added to protosulphate of iron metallic silver is precipitated. The alkalis throw down a colourless hydrate, and the alkaline carbonates precipitate protocarbonate of iron. The salts of iron which contain the peroxide, or sesquioxide, are distinguished from those of the protoxide by giving a deep blue or black precipitate with tincture of galls; the ferrocyanide of potassium also gives a deep blue, but the sesquiferrocyanide gives none at all. Hydrosulphuric acid reduces them to the state of protoxide, sulphur being precipitated. Ammonia, and the solutions of potash and soda, give a yellowish hydrate.



There are however some exceptions to the production of these effects: thus the tartrate of potash and peroxide of iron, the ferri potassio-tartras of the Pharmacopœia, gives no blue precipitate with ferrocyanide of potassium, nor is it precipitated by ammonia or the alkaline carbonates; but potash, when the mixture is heated, throws down hydrated peroxide of iron.

IRON MANUFACTURE AND TRADE.—The art of smelting iron was practised in this country during the time of the Roman occupation and in many antient beds of cinders, the refuse



of iron-works, Roman coins have been found. The principal antient seats of the iron manufacture in this country appear to have been Sussex and the Forest of Dean, or Arden, as it was then called. It is known that iron-works existed in that part of Gloucestershire in 1238, because there occurs among the patent rolls of Henry III. of that date, one entitled 'De Forgeis levandis in foresta de Dean.' Remains of antient iron-furnaces have been noticed in Lancashire, Staffordshire, and Yorkshire. The art of working in iron and steel was much practised in this island before the Norman conquest, and we are told that not only was the army of Harold well supplied with weapons of steel and with defensive armour, but that the horses were covered with steel and iron armour, and that every officer of rank maintained a smith, who constantly attended his master to the wars, and took charge of his arms and armour to keep them in proper repair.

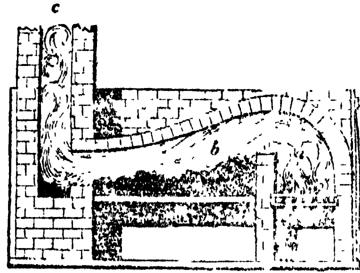
There are two distinct qualities into which this metal is commonly divided, viz. pig-iron, and malleable or bar iron, the second being the result of an extension of the processes necessary for the production of the first kind—pig-iron.

The first process is that of reducing the iron-stone or ore, or, as it is technically called, the *mine*, into a metallic state by means of fusion. This operation is conducted in a blast-furnace, the form and construction of which will be understood from the following section. The interior of this

furnace in the broadest part, which is called the *boshes*, is usually from 14 to 17 feet in diameter, and this is gradually decreased to about half that diameter at the top. The whole is built of masonry, the lining to the furnace being composed of fire bricks carefully jointed together with fire-clay: the whole furnace is strongly bound together with iron hoops or stays. The furnace is again contracted below the boshes, and into this lower part the melted iron falls as it is formed. The ground-plan of this lower part of the furnace is constructed according to the following diagram, where the unshaded square in the centre represents the

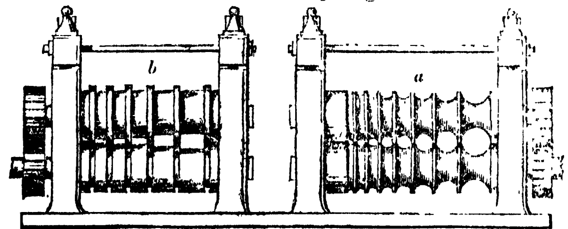
hearth, and is about 3 feet square. The three tubes leading to this hearth (two of which are shown in the section above), and which are called *tuyeres*, are used for introducing the blast of air required to give the degree of intenseness to the heat which is necessary for fusing the ore. The furnace is charged from the top with certain proportions of iron-ore, of coke, and of limestone. The ore must previously have been roasted or calcined in a kiln, in order to drive off the water, sulphur, and arsenic, with which it is more or less combined in its native state: by this process it loses one-sixth part of its weight. A furnace of the size commonly used in Wales will produce from 5 to 6 tons of pig-iron in twelve hours. For the largest quantity the furnace must be charged progressively with 15 tons of roasted iron-ore, 22½ tons of coke, and about 6 tons of limestone. These ingredients are supplied at 50 charges, and must be intimately mixed together in the furnace. The limestone must be broken into small pieces; its use is to act as a flux to the ore and promote its fusion. The heat that would be produced in any furnace by merely setting fire to the fuel which is contained in it would be altogether insufficient for the fusion of the ore, if its intenseness were not promoted by the forcing in of a current or blast of air. For this purpose it is necessary to use a strong mechanical force, and of late years the agency of steam has been most commonly employed for this purpose. Water-wheels, where they can be had, are of course cheaper agents; but there are not many places where a sufficiently copious and regular supply of water at all seasons can be commanded, and the success of an iron-work would be destroyed by the failure of the blast in any degree for even a short time. Steam-engines are therefore usually preferred. This power is applied to the working of a blowing cylinder, which may be four times the area of the cylinder of the steam-engine. If the blast thus produced were passed immediately from the blowing cylinder through the tuyeres to the furnace, the effect would be intermitting and irregular, ceasing at the end of each stroke of the steam-piston. To remedy this inconvenience the blast is carried into an intermediate chamber of a spherical or cylindrical shape, called a regulator, and as the air is in a state of condensation when admitted, its effort to expand itself again to its natural volume causes the continuous and regular supply to the furnace which is necessary. The air thus forced into the furnace keeps the heat at the degree of intenseness which is indispensable for the smelting of the ore. Until the last few years the air thus supplied was uniformly at the temperature of the atmosphere from which it was immediately taken, and the effect was not only to produce a lower degree of heat, but also to supply a quantity of moisture which is prejudicial to the smelting process. Atmospheric air always contains moisture in some degree or other, but holds a larger proportion in hot than in cold weather, for a very obvious reason, and this causes the furnaces not to work so well in summer as in winter. By the previous drying and heating of the air these inconveniences are remedied, the consumption of fuel is lessened, and the absence of moisture is said to have a beneficial effect upon the quality of the iron produced. This improvement is the invention of Mr. Neilson, of the Clyde Iron-works, and has been made the subject of a patent. It is probable that when, by the expiration of the term of the patent, this invention may be freely used without compensation to the inventor, it will be adopted universally; at present it is used only partially, but still in an increasing degree, and its adoption has very recently made great progress in France, where it has been strongly recommended by the government engineers, after one of them, M. Le Play, had investigated the subject in Scotland in 1836. The air, before it is forced into the furnace, is heated in cast-iron vessels to about 300° Fahr., and is thus more nearly than when at its natural temperature in a condition to support combustion. The saving of fuel in the furnace is found to exceed by ten times its weight the quantity of coal used for the preliminary heating of the air. It is supposed that the improved quality of hot-blast iron is the result of the state of dryness which is thus attained.

The iron is run from the furnace every twelve hours, by tapping it in the front, on a level with the bottom of the hearth, at the side on which, as will be seen from the diagram, there is no tuyere introduced. When the furnace is tapped the metal is allowed to run into channels formed in the sand of the smelting-house floor. The names of *sow-metal* and *pig-metal*, which were originally given by the workmen, signify in one case the blocks of iron which are formed in the large main channels, and in the other case the smaller blocks which are formed in smaller side channels communicating with the larger ones; these names were adopted from the fancied resemblance of the cast



metal to a sow and her litter of pigs: this is iron in its crudest state. The weight of materials lost in its production is somewhat greater than that of the fuel used; taking into account the refuse cinder and ashes with the metal, the whole does not weigh quite so much as the ore and lime that have been put into the furnace. Large heaps of cinder are gradually accumulated in the neighbourhood of iron-works, and give a dreary aspect to the country.

The quality of pig-iron varies according to the purposes for which it is intended, and depends not only upon the quality of the ore, but also upon that of the fuel. The principal division is into foundry-iron and forge-iron, the former being used for castings, the latter for conversion into malleable iron. Foundry-iron is further divided into three qualities, distinguished by the numbers 1, 2, and 3. No. 1 contains a large proportion of carbon, which it has acquired from the coke used in smelting, and the quality of which has been chosen with a view to the production of this kind of iron, which is soft and very fluid when melted, so that it will run into the finest and most delicate forms the moulder can produce. No. 2 contains a smaller proportion of carbon; it is harder than No. 1, closer grained, and of more regular fracture; it is more refractory in the furnace, and does not run so freely when melted as No. 1, but as it is harder and stronger it is preferred for purposes where strength and durability are required in preference to delicacy of form: these two kinds are unfit for conversion into bar-iron. No. 3 varies in the same direction as No. 2, but in a greater degree, from the qualities of No. 1; it is used for many kinds of heavy work where it has to bear great strains and is exposed to constant wear. Forge-iron is divided also into three qualities, and is distinguished as *bright iron*, *mottled iron*, and *white iron*, which names are indicative of the appearance which each quality presents to the eye; they all of them contain some carbon, but less than foundry-iron, and in proportions diminishing in the order in which they are here mentioned, white iron having the smallest proportion of any, and being exceedingly hard; its fluidity too is so small that it runs with difficulty into the channels provided to receive it at the first smelting, and it is altogether incapable of being afterwards used for foundry purposes.



Forge or bar iron is pig-iron freed from carbon and oxygen. The first operation for producing this change is called refining, and is performed in small low furnaces about three feet square at the base, having the bottom, or hearth, of fire-bricks, and the sides of cast-iron, made hollow to allow a stream of water to pass constantly through, which prevents their being quickly burnt away; near the top are holes for the insertion of blast-pipes. These refineries have iron doors at the back, but are open in front; the whole is surmounted by a chimney of brick-work carried to the height of 20 feet from the ground. At the level of the hearth in front is a hole similar to that in the smelting-furnace for running out the melted metal. This communicates with a flat mould of cast-iron 20 feet long and two feet wide, placed over a cistern of water with which its under surface is in contact, and which serves to cast the metal rapidly as it runs into the mould. The iron is kept in a state of fusion in the refinery for some time exposed to an intense heat produced by a strong blast. From the sudden cooling to which it is exposed, the plate when run into the mould is very brittle: when broken the fracture presents a bright silvery appearance. The operation of refining requires about two hours for its performance, and as the weight of each plate when run out is about one ton, each refinery is capable of being made to yield about 70 tons weekly. From 22 to 23 hundred-weight of pig-iron are required to produce one ton of refined iron, and from 10 to 12 cwt. of coke is used for the purpose.

The first process employed for making bars is called puddling, and is performed in a reverberatory furnace, thence called a puddling-furnace: the structure of this furnace will be explained by the following diagram:—In this diagram *a* is the grate, which is supplied with coal through a door in the side. The refined metal broken in small fragments is placed in the body of the furnace *b*, over which the flame is made to play in its passage to the chimney *c*.

The degree of the draft is regulated by a damper on the top of the chimney, which is about 30 feet high. Such is the intenseness of the heat in these furnaces, that when the damper is raised the flame is sometimes carried to the top of the chimney. The quantity of refined metal put

into this puddling-furnace at each charge is from 3½ to 4 cwt. In about half an hour from the charging of the furnace the metal begins to melt. The puddler then observes, through a small hole provided for that purpose and for the introduction of his tools, the progress of the work. The business of the puddler is so to dispose of the pieces of metal, moving them by means of his tools, as to ensure an equable application of heat to the mass. When the whole quantity is fully melted, the puddler stirs the metal about briskly, changing his tools continually that they may not be melted. By means of this agitation the metal gives off an elastic fluid, and after a time becomes thick, and grows increasingly so, until it loses all fluidity and forms into lumps. The contents of the furnace are then divided into five or six portions by the puddler, and each is made up by means of his tools into a spherical form. These balls are technically called *blooms*. Being taken from the puddling-furnace they are subjected each to 10 or 20 blows from a heavy hammer (called shingling), which makes them more compact and gives them a shape more convenient for going through the rollers. The form and construction of these rollers are shown in the following diagram. The bloom is

passed in succession through the holes in *a*, beginning with the largest and proceeding to the smallest; it is then passed through the grooves in the second roller *b*, and is thus reduced to the requisite width and thickness, having by these several processes been converted from a fusible, hard, and brittle substance, to a tough and elastic bar which is hardly fusible, and which from its property of yielding and altering its form under the hammer has acquired the name of malleable iron.

The quantity of refined metal required to make one ton of these rough bars is about 22 cwt., and the quantity of coal consumed in the process is about 17 cwt. The bars, when they have been passed through these rollers, and while yet hot, are cut into convenient lengths and taken to the balling-furnace, the shape and construction of which resemble those of the puddling-furnace. In this balling-furnace the bars are piled evenly, so that one bar does not project beyond another. Several of these piles, each of which is composed of five or six bars, are placed at once in the furnace, and when sufficiently heated, so that they will weld together, the piles are taken out separately and are passed again through rollers similar in construction to those described above, but differing from each other in the form of their orifices and grooves, so that either round or flat or square rods and bars may be produced at the pleasure of the maker, and these when weighed and put up into bundles are ready for sale.

There are no means of ascertaining correctly the quantity of iron made in this country. Estimates have been formed at different periods, but these are at best but approximations to the truth: these estimates are as under:—

1740 . . .	17,000 Tons.
1788 . . .	68,000 „
1796 . . .	125,000 „
1806 . . .	250,000 „
1820 . . .	400,000 „
1827 . . .	690,000 „

More recently (in 1836) the gentleman who has been already mentioned as an engineer in the employ of the French government, M. Le Play, having visited every ironwork in the United Kingdom, ascertained that the quantity produced was one million of tons, which was probably not beyond the truth at that time. In the following year several furnaces were put out of blast, but it is probable that the quantity in 1838 will again reach, if it do not exceed, the quantity just mentioned. The quantity of iron conveyed upon the Monmouthshire and Glamorganshire canals in 1837 amounted to 256,810 tons, including 20,000 tons of railway iron from the Dowlais works alone.

The manufacture of iron has increased very considerably of late years in France, and since the establishment of mining inspectors in that country we know precisely the quantity produced within the year. Since 1832 the produce has been—

	Pig Iron Tons.	Malleable Iron. Tons.
1832 . . .	221,660 . . .	141,336
1833 . . .	232,559 . . .	149,982
1834 . . .	265,028 . . .	174,507
1835 . . .	290,378 . . .	206,396
1836 . . .	303,739 . . .	201,691

The iron trade of England in all its various branches is of very great importance. Its growth since 1814 has been exceedingly rapid, as will be seen by the following statement of exports in each year:—

Year	Bar Iron Tons.	Pig Iron Tons.	Castings. Tons.	Hardwares & Cutlery. Tons.	Steel unwrought. Tons.	Total declared Value. £
1814	15,168	307	5,034	6,162	323

IRON, *Medicinal Properties*. [CHALYBEATE SPRINGS.]

IRON BRIDGES. [BRIDGES.]

IRONY (εἰρωνεία), a refined species of ridicule, which under the guise of earnestness and simplicity exposes all undue pretensions, even while it professes to honour and admit them. It stands intermediate between naïveté, or frank simplicity, on the one hand, and banter and persiflage, on the other. From the former it is distinguished by the consciousness and intention of ridicule, which object again is more covert and less transparent in irony than in the latter. By Aristotle the ironical is opposed to the boastful (τῷ ἀλάζονι), and as a middle term between *the two* he places the truthful (τὸν ἀληθῆ). The Latins translated the word irony by 'dissimulatio,' which however Quintilian (lib. ix., c. 2) disapproves of as very inadequate, and preferred the original, for which we are indebted to the refinement of the Athenians, among whom Socrates, the master in this art, was called emphatically the Ironical (ὁ εἴρων). The strict etymology of the term is very doubtful. One explanation, looking to the so-called Socratic method of question and answer, takes it to mean simply 'the interrogator;' while another would derive it from εἴρειν, to fasten, which may have had reference to the skill wherewith Socrates reduced the sophists to the necessity of adopting some fixed and stable point for discussion, instead of loose and slippery declamation, which, as more favourable to delusion and fallacy, they preferred. Both explanations equally leave out of consideration that element of latent mockery which predominates in the modern acceptation of the word, but which was probably only accessory to the original idea. For while the serious object of the Socratic irony, in which he presented himself as desirous to learn of those whose claim to wisdom he laboured to expose, was to awaken reflection by the development of the consciousness, he nevertheless combined with it all the Attic urbanity and wit. It was consequently of two kinds, a finer and a grosser, according as he had to do with the more presumptuous arrogance of the sophists, whose undue and pernicious reputation he sought to subvert, or with those younger but not less conceited spirits, who yet sought his society for the sake of benefit and improvement, and therefore required a milder and more merciful treatment.

The ironical argument proceeds in simulated ignorance, and by appearing to agree with those whom its purpose is to refute, in holding certain erroneous opinions and maxims, brings out the antagonism of truth to error, and gradually involves them in inextricable difficulties. On this account it has been considered a species of apogogical argument (τῆς εἰς ἀδύνατον ἀπαγωγῆς), or reductio ad absurdum.

As a figure of rhetoric, it is correctly defined to be that mode in which our words convey a sense directly contrary to what we express, but agreeable to what we mean and are understood to mean. (Beattie, *Moral Science*, c. i. § 1, p. 4.) In an opposite and somewhat extended sense those mistakes have been called ironical wherein our intended expressions receive an inverted signification.

Since the essence of irony consists in its serious and seeming simplicity, it is essential to its successful application that it should advance gradually to its ultimate object of exposure, and neither lose its covert character by rising too suddenly to exaggeration and extremes, nor yet so closely veil itself but that the intention of ridicule may appear through the assumed mask of earnestness and simplicity.

Of English writers Swift contains the strongest and the most numerous examples of irony.

IROQUOIS, or MOHAWKS, an Indian tribe in North America, formerly known also under the name of Mengwe, or Six Nations, inhabited the country between the present town of Montreal and Lake Ontario. This once powerful and numerous tribe gradually diminished as the European settlements in their country increased, and at present the number of individuals composing it probably does not exceed 1600. They inhabit two villages not far from the southern banks of the river St. Lawrence. Coghnawaga, opposite the island of Montreal, contains about 900 inhabitants, and St. Regis more than 700. The last-mentioned village is situated where the boundary-line between Canada and the United States strikes the river St. Lawrence, so that one half of the village is within the British territories and the other belongs to the state of New York. The Iroquois have quite changed their manner of life; they derive their subsistence from the produce of their fields, in which they cultivate rye, Indian corn, potatoes, and peas, and from the rearing of some poultry and hogs. They also fish and hunt, but these are no longer considered their principal employment. Their language, which they still speak, differs considerably from that of the Crees, who inhabit the country farther west, but does not seem to differ from that of the Wyandots, Nadowessies, and Asseneepoytuck, and hence the language of all these tribes is called Iroquois.

(Bouchette, *Topogr. Diction. of Lower Canada*; Carver's *Travels through North America*; Dr. Richardson, in Franklin's *First Journey to the Polar Sea*.)

IRRATIONAL QUANTITY. The distinction between quantity in general and number, or rather between the ratio of quantity to quantity, and that of number to number, has begun to appear in the article INCOMMENSURABLE, of which the present may be taken as a continuation. It there appears that there are such things as magnitudes which are not in the proportion of any one number to any other; though if we may use numbers as great as we please, we can find a pair which shall be as nearly as we please in the ratio of any two given incommensurable quantities.

According to the modern use of the term irrational, it simply means not expressible by a finite fraction. The word *ratio*, or its equivalent λόγος, does not here mean reason, in the common sense of the word, but mathematical proportion. A quantity whose proportion to the unit of quantity cannot be expressed arithmetically, that is, by a whole number, or a fraction, is 'inexpressible by an arithmetical ratio,' or 'arithmetically irrational,' abbreviated into

'irrational.' This explanation is very important, since the student might otherwise be led to suppose that irrational meant unreasonable, or absurd. Suppose for example that we have a geometrical problem which we solve by the application of arithmetic, taking a certain line to be one, and applying the fundamental principles explained in RECTANGLE. Suppose the problem thus reducible to the solution of $x^2 = 2$, or the quantity sought is such a fraction as multiplied by itself will give 2. The arithmetical answer is very simple; there is no such fraction. But is the problem therefore impossible? By no means; for the line required must be the diagonal of a square whose side is the linear unit. What then is the reason for our not being able to produce an arithmetical solution? Because the ratio of the line sought to the linear unit given is not to be expressed arithmetically, or is in the preceding sense irrational. The student has now arrived at the point where he must be taught (if he have not learnt it before) that arithmetic is not the science of all ratios or relative magnitudes, but only of the ratios or relative magnitudes of those quantities which are made by putting together quantities which are all equal to one another. The senses alone would never make this distinction, and those who desire nothing more than sensible evidence in their mathematical studies need not attend to it: unfortunately the present bent of such pursuits tends to inexactness, not explicitly avowed, but wearing the appearance of absolute rigor.

The student who begins to extract the square root of numbers is allowed to place the symbol of that process over numbers which do not admit of its performance, as $\sqrt{2}$, $\sqrt{3}$, &c. These symbols are reasoned on as if they represented fractions, and arithmetical deductions are drawn: but when it is required to reduce them to practice, then the possibility of determining their arithmetical values is denied, and it is implied that they have an existence which can only be approximately represented. Thus, since 1·4142 multiplied by itself gives 2 very nearly; it is said that 1·4142 is very nearly the square root of 2. This method, which is indispensably necessary in practice, should not be allowed in perfectly strict reasoning. It cannot be just to say that 2 has no square root, but that since fractions very near to 2 have square roots, therefore these square roots are very near to the non-existent square root of 2. It is only in a properly extended arithmetic, which by express agreement admits of extended symbols of ratio, that it can be lawful to speak of the square root of 2. [RATIO.] Waiving this point for the present, we proceed to further considerations, confining ourselves to those irrational quantities which arise from taking the square roots of numbers, but premising that similar remarks might be made on cube, fourth, &c. roots. If we take the series of numbers 1, 2, 3, &c., and extract the square root of each, we thereby obtain (1.) the original series 1, 2, 3, &c., by means of $\sqrt{1}$, $\sqrt{4}$, $\sqrt{9}$, &c.; (2.) a series of multiples of $\sqrt{2}$, namely, $\sqrt{2}$, $\sqrt{8}$, $\sqrt{18}$, &c., which are $\sqrt{2}$, $2\sqrt{2}$, $3\sqrt{2}$, &c.; (3.) a similar series of multiples of $\sqrt{3}$; and so on ad infinitum. The primitive numbers are either prime numbers or products of *different* prime numbers. Thus we have a series of multiples of $\sqrt{(7 \times 5)}$, but not of $\sqrt{(7 \times 7 \times 5)}$, since this last is $7\sqrt{5}$, and, with its multiples, is included in those of $\sqrt{5}$. Any two quantities in the same series are commensurables; thus $7\sqrt{10}$ and $12\sqrt{10}$ are in the proportion of 7 to 10, and have $\sqrt{10}$ for a common measure: but any two which are in different series are incommensurables; thus $\sqrt{10}$ and $\sqrt{11}$ have no common measure whatsoever. And the sum or difference of any two incommensurable quantities is incommensurable with either; thus we can form infinite sets of binomials, such as $\sqrt{2}+\sqrt{3}$, $\sqrt{10}+\sqrt{11}$, $\sqrt{19}-\sqrt{5}$, &c., no one of which shall be commensurable with any other.

The square root of any arithmetical fraction is commensurable with that of the product of its numerator and denominator: thus $\sqrt{(\frac{3}{5})}$ is $\frac{1}{5}\sqrt{15}$. And the reciprocal of any square root is commensurable with that square root: thus $1 \div \sqrt{7}$ is $\frac{1}{7}\sqrt{7}$. Also the fraction made by any two of the binomials just described is commensurable with the product of some similar pair: thus

$$\frac{\sqrt{3}+\sqrt{5}}{\sqrt{10}-2} = \tfrac{1}{6}(\sqrt{3}+\sqrt{5})(\sqrt{10}+2).$$

If we take the square root of one of the preceding binomials, as $\sqrt{(\sqrt{3}+\sqrt{5})}$ we have a new quantity, not commensurable with any of those just mentioned, except only in certain cases pointed out by the following theorem. Let a and b be two numbers, of which a is the greater:

$$\sqrt{(\sqrt{a} \pm \sqrt{b})} =$$

$$\sqrt{\left(\frac{\sqrt{a}+\sqrt{(a-b)}}{2}\right)} \pm \sqrt{\left(\frac{\sqrt{a}-\sqrt{(a-b)}}{2}\right)}$$

If a and $a-b$ be both square numbers, let $a = p^2$, $a-b = q^2$, and we have

$$\sqrt{(\sqrt{a} \pm \sqrt{b})} = \tfrac{1}{2}\sqrt{(2p+2q)} \pm \tfrac{1}{2}\sqrt{(2p-2q)}.$$

Though Euclid was not acquainted with any direct algebraical process, yet he carried the distinction of incommensurable quantities to the length of a complete subdivision of all the possible cases which can be contained in the formula $\sqrt{(\sqrt{a} \pm \sqrt{b})}$. We are induced to give an account of his tenth book, because there does not, to our knowledge, exist any such thing in a form accessible to the student. Indeed, we do not know where to find a description of its details in any form whatsoever. In old geometrical writings references to the classification of this book are not unfrequently met with. If we take any given line to represent the unit of length, and if a, b, c, &c., represent lines commensurable with this unit, arithmetically expressed, it is well known that the most common geometry shows how to find the lines expressed by $\sqrt{a}$, $\sqrt{b}$, &c. All such lines Euclid terms rational, all others irrational (ῥητός and ἄλογος); and any area which being formed into a square has a rational side, he calls a rational area; that is in fact any area which is commensurable (σύμμετρος) with the square unit, is rational. The term for the square on a line is its *power* (δύναμις) and from this comes the algebraical use of the word power. Thus when he says that two lines are only commensurable in power, he means that the squares on them are commensurable, but not the lines themselves. A mean, or medial line (μέσος), is the mean proportional between two incommensurable rational lines, and is such as can be represented in algebra by $\sqrt[4]{a}$, where a is commensurable with the unit: and a medial area is the mean proportional between two rational areas, and its number of square units may be represented by $\sqrt{a}$.

A line which is made by putting together (σύνθεσις) two incommensurable rational lines is called a line of two names (ἐκ δύο ὀνομάτων), or a binomial line; while one which is made by taking away (ἀφαίρεσις) the lesser of two incommensurable rational lines from the greater, is called an apotomé (ἀποτομή) literally, off-cut. The binomial therefore has one of the forms $a+\sqrt{b}$ and $\sqrt{a}+\sqrt{b}$, while the apotomé has one of the forms $\sqrt{a}-\sqrt{b}$, $a-\sqrt{b}$, $\sqrt{b}-a$. Six distinct species of each sort of line are found, and in connection with each set of six is another similar set, which a modern mathematician would describe as composed of the square roots of the first set. But Euclid describes the square roots, as we should call them, previously to the lines themselves, and in order to render this article more available to those who look through the tenth book, we shall do the same. The whole amounts to this, that taking a given line as the unit and standard, Euclid separates the lines represented by $\sqrt{(\sqrt{a} \pm \sqrt{b})}$, where a and b are commensurable with the standard unit, into twenty-five distinct classes, no one of which contains any lines commensurable with those of any other class. The following enumeration contains the order in which they make their appearance: a, b, &c., representing lines commensurable with the standard unit; A, B, C, D, E, F, the six binomial lines; $\sqrt{A}$, $\sqrt{B}$, &c., those connected with them; U, V, W, X, Y, Z, the six apotomæ; $\sqrt{U}$, $\sqrt{V}$, &c., those connected with them.

It is however to be noticed that Euclid does not use the term unit, but supposes a rational line, to which he makes reference. Thus when he mentions in one place a rational line and a fourth binomial, he means that the fourth binomial shall be related to that rational line in the same manner as our following definition will connect it with the modern phrase, the standard unit.

(1). a, b, &c., lines commensurable with the unit.

(2). $\sqrt{a}$, $\sqrt{b}$, &c., lines commensurable in power with the unit. These two heads include the rational lines.

(3). $\sqrt[4]{a}$, $\sqrt[4]{b}$, &c., medial lines, described by Euclid as lines equal in power to the rectangle of incommensurable rational lines.

( ). $\sqrt{A}$ has the form $\sqrt{a}+\sqrt{b}$. A binomial line generally. This case contains all the six hereafter described and numbered, for which reason the numbering is here left blank. There is a proposition which we should now enunciate by saying that the square root of a binomial of the first species

(A) is one or other, and may be either, of the six binomials.

(4). $\sqrt{B}$ has the form $(\sqrt{a}+\sqrt{b})\sqrt[4]{x}$, where abx is a square number. It is the first species of line composed of two medials, or a first bi-medial, and is compounded of two medials, which make a rational rectangle (εὐθεῖα ἐκ δύο μέσων πρώτη).

(5). $\sqrt{C}$ has the form $(\sqrt{a}+\sqrt{b})\sqrt[4]{x}$, where abx is not a square number. It is the second species of line composed of two medials, or a second bi-medial, and is compounded of two medial lines, which make a medial rectangle (εὐθεῖα ἐκ δύο μέσων δευτέρα).

(6). $\sqrt{D}$ has the form $\sqrt{(a+\sqrt{b})}+\sqrt{(a-\sqrt{b})}$, where a^2-b is not a square. It is described by Euclid as composed of two straight lines, incommensurable in power, whose squares together make a rational space, but whose rectangle is a medial space, and is called by him a greater line (εὐθεῖα μείζων).

(7). $\sqrt{E}$ has the form $\sqrt{(\sqrt{a}+\sqrt{b})}+\sqrt{(\sqrt{a}-\sqrt{b})}$, where $a-b$ is a square. It is described by Euclid as composed of two straight lines incommensurable in power, whose squares together make a medial space, but whose rectangle is a rational space; and it is called by him 'a line in power making a rational and a medial space' (εὐθεῖα ῥητὸν καὶ μέσον δυναμένη). The nomenclature is not here quite correct, for the preceding line, called a greater line, is also a line in power equal to a rational and medial space.

(8). $\sqrt{F}$ has the form $\sqrt{(\sqrt{a}+\sqrt{b})}+\sqrt{(\sqrt{a}-\sqrt{b})}$, where $a-b$ is not a square. It is described by Euclid as composed of two lines incommensurable in power, making both the sum of their squares and their rectangle medial spaces incommensurable with one another; and it is called 'a line in power equal to two medial spaces' (εὐθεῖα δύο μέσα δυναμένη).

We now come to the description of the six binomial lines themselves.

(9). A has the form $a+b+2\sqrt{(ab)}$. It is described by Euclid as having the greater term commensurable with the standard unit, and more in power than the less by the square of a line commensurable with itself in length; and it is called the first binomial line (εὐθεῖα ἐκ δύο ὀνομάτων πρώτη).

(10). B has the form $(a+b+2\sqrt{(ab)})\sqrt{x}$, where abx is a square. It is described as differing from the first binomial only in having the lesser term commensurable with the standard unit; and is the second binomial line.

(11). C has the form $(a+b+2\sqrt{(ab)})\sqrt{x}$, where abx is not a square. It differs from the two preceding only in neither term being commensurable with the standard unit.

In the first three binomial lines, reduced to the form $\sqrt{p}+\sqrt{q}$, $\sqrt{(p-q)}$ is commensurable with $\sqrt{p}$, the greater term: in the last three these two are incommensurable.

(12). D has the form $a+\sqrt{b}$, where a is greater than $\sqrt{b}$, and a^2-b is not a square. Euclid describes it as having the greater term more in power than the less by the square of a line incommensurable to itself in length, the same greater term being commensurable with the standard unit: it is the fourth binomial line.

(13). E has the form $a+\sqrt{b}$, where $\sqrt{b}$ is greater than a, and $b-a^2$ is not a square. It is described as differing from the preceding by having the less term commensurable with the standard unit: it is the fifth binomial line.

(14). F has the form $\sqrt{a}+\sqrt{b}$ where $a-b$ is not a square. It is described as differing from the two preceding by neither term being commensurable with the standard unit; and is the sixth binomial line.

We now come to the lines derived from the apotomæ, and afterwards to the apotomæ themselves. The descriptions might be shortened by allusion to the corresponding binomial lines, but this would impede the speedy reference to the complete meaning of any one term.

( ). $\sqrt{U}$ has the form $\sqrt{a}-\sqrt{b}$. An apotomé generally. The numbering is left blank, as this class of lines is afterwards subdivided. A proposition is proved, which we should now enunciate by saying that the square root of an apotomé of the first kind is one or other, and may be any of the six apotomæ.

(15). $\sqrt{V}$ has the form $(\sqrt{a}-\sqrt{b})\sqrt[4]{x}$ where abx is a square. Euclid describes it as the difference of two medial lines which are commensurable in power, and whose rectangle is a rational space. He calls it the first kind of apotomé of a medial line (μέσης ἀποτομὴ πρώτη).

(16). $\sqrt{W}$ has the form $(\sqrt{a}-\sqrt{b})\sqrt[4]{x}$, where abx is not a square. It is described as differing from the former only in the medial lines containing a medial space, and is the second apotomé of a medial line.

(17). $\sqrt{X}$ has the form $\sqrt{(a+\sqrt{b})}-\sqrt{(a-\sqrt{b})}$ where a^2-b is not a square. Euclid describes it as the difference of two straight lines incommensurable in power, the sum of whose squares is rational, and their rectangle medial: and he calls it a lesser line (εὐθεῖα ἐλάσσων).

(18). $\sqrt{Y}$ has the form $\sqrt{(\sqrt{a}+\sqrt{b})}-\sqrt{(\sqrt{a}-\sqrt{b})}$ where $a-b$ is a square. It is described as the preceding, except that the sum of the squares is medial, and the rectangle rational: and Euclid calls it 'a line which with a rational space makes a medial space' (εὐθεῖα μετὰ ῥητοῦ μέσον τὸ ὅλον ποιοῦσα) meaning that a certain rational space added to the square on it makes a whole space, which is medial. There is not here the defect of nomenclature mentioned in (7), for the preceding line here can only be called 'a line which with a medial space makes a rational space.'

(19). $\sqrt{Z}$ has the form $\sqrt{(\sqrt{a}+\sqrt{b})}-\sqrt{(\sqrt{a}-\sqrt{b})}$ where $a-b$ is not a square. It is described by Euclid as the difference of two lines incommensurable in power, having the sum of their squares and their rectangle both medial: and it is called 'a line which with a medial space makes a medial space (εὐθεῖα μετὰ μέσου μέσον τὸ ὅλον ποιοῦσα).

The six apotomæ now follow, all in the form $\sqrt{a}-\sqrt{b}$; in the first three $\sqrt{(a-b)}$ is commensurable with $\sqrt{a}$, in the second three, incommensurable. And $\sqrt{a}$ is called the whole, but $\sqrt{b}$ is called the fitted or adapted line.

(20). U has the form $a+b-2\sqrt{(ab)}$. The whole is commensurable with the standard unit, and exceeds it the adapted line in power by the square of a line commensurable to itself. Euclid calls this a first apotomé.

(21). V has the form $(a+b-2\sqrt{(ab)})\sqrt{x}$ where abx is a square. Described as the preceding, except that only the adapted line is commensurable with the standard unit; and is the second apotomé.

(22). W has the form $(a+b-2\sqrt{(ab)})\sqrt{x}$, where abx is not a square. Here neither the whole nor the adapted line is commensurable with the standard unit; this is the third apotomé.

(23). X has the form $a-\sqrt{b}$ where a^2-b is not a square. Euclid describes it by saying that the whole is commensurable with the standard unit, and exceeds the adapted line in power by the square of a line incommensurable with itself; and calls it the fourth apotomé.

(24). Y has the form $\sqrt{b}-a$ where $b-a^2$ is not a square. Described as the last, excepting that only the adapted line is commensurable with the standard unit: it is the fifth apotomé.

(25). Z has the form $\sqrt{b}-\sqrt{a}$ where $b-a$ is not a square. It differs from the two preceding by neither term being commensurable with the standard unit: and is the sixth apotomé.

Besides obtaining this classification, Euclid proves, firstly, that every one of these species is distinct from every other, and that every line which is commensurable with a line of any one species is itself a line of the same species. He shows also how to find lines of every species, in which he directly applies the theory of numbers obtained in the seventh, eighth, and ninth books. He also demonstrates that no straight line can belong to one species in two different ways: proving, for example, an equivalent to the following, that $\sqrt{a}+\sqrt{b}$, if the terms be incommensurable, cannot be equal to $\sqrt{x}+\sqrt{y}$, where x differs from a, and y from b: which he expresses thus:—'a binomial line is divided into its names (or terms) in one point only.' He then proves that the lines which we have denoted by $\sqrt{A}$, $\sqrt{B}$, &c., are derived from A, B, &c., in the manner which justifies our notation. For instance, 'if a space be contained by a rational and a fourth binomial line, the line equal in power to the space is the irrational line called a greater line.' Now, c representing a rational line, a fourth binomial derived from it has the form $a+\sqrt{b}$ where a is commensurable with c, and greater than $\sqrt{b}$, and $\sqrt{(a^2-b)}$ is not commensurable with c. His proposition then amounts to this, that $\sqrt{(ca+c\sqrt{b})}$ has the form

$$\sqrt{(x+\sqrt{y})}+\sqrt{(x-\sqrt{y})}$$

where $2x$ is a rational space (or the number $2x$ commensurable with c^2), and x^2-y is an irrational space, or that number is incommensurable with c^2. This involves the algebraical proposition, that the square root of $ca+c\sqrt{b}$ is

$$\sqrt{\{\tfrac{1}{2}ca+\tfrac{1}{2}c\sqrt{(a^2-b)}\}}+\sqrt{\{\tfrac{1}{2}ca-\tfrac{1}{2}c\sqrt{(a^2-b)}\}};$$

and in showing the identity of the forms, Euclid arrives at the manner of deriving one from the other. He also shows, in two propositions, that the form $\sqrt{(a+\sqrt{b})}$ gives either a binomial line, or (4), (6), or (7) of the preceding enumeration, and that $\sqrt{(\sqrt{a}+\sqrt{b})}$ gives either (5) or (8). In three more he shows that $\sqrt{(a-\sqrt{b})}$ gives either an apotomé or (17) of the enumeration, that $\sqrt{(\sqrt{b}-a)}$ gives either (15) or (18), and that $\sqrt{(\sqrt{a}-\sqrt{b})}$ gives either (16) or (19). He further shows the equivalent of the following algebraical proposition:—

$$\frac{1}{\sqrt{a}-\sqrt{b}}=\frac{\sqrt{a}+\sqrt{b}}{a-b}$$

The preceding enumeration points to one of the most remarkable pages in the history of geometry. The question immediately arises, had Euclid any substitute for algebra? If not, how did he contrive to pick out, from among an infinite number of orders of incommensurable lines, the whole, and no more than the whole, of those which were necessary to a complete discussion of all lines represented by $\sqrt{(\sqrt{a}\pm\sqrt{b})}$, without one omission or one redundancy? He had the power of selection, for he himself has shown how to construct an infinite number of other species, and an algebraist could easily point out many more ways of adding to the subject, which could not have been beyond Euclid. If it be said that a particular class of geometrical questions, involving the preceding formula and that one only, pointed out the various cases, it may be answered that no such completeness appears in the thirteenth book, in which Euclid applies his theory of incommensurables. It is there proved that each of the segments of a line divided in extreme and mean ratio is an apotomé—that the side of an equilateral pentagon inscribed in a circle is, relatively to the radius, the irrational line called a lesser line, as is also the side of an icosahedron inscribed in a sphere—and that the side of a dodecahedron is an apotomé. The apotomé then and the lesser line are the only ones applied.

It seems probable that the distinction of commensurable and incommensurable, and even a notion of different species of incommensurables, was familiar to the geometer before Euclid wrote. Had it been otherwise, we must suppose that the definitions of the fifth book would have been accompanied by some little account of their necessity, and also that the absolute determination of two incommensurable magnitudes would not have been postponed till the last proposition of the tenth book. But it is impossible to draw any very positive conclusion on this subject. Owing to the loss of Euclid's book on Fallacies [GEOMETRY, p. 162], we are probably left without those notions which he intended to be preliminary to the elements.

The most conspicuous propositions of elementary geometry which are applied in the tenth book are the 27th, 28th, and 29th of the sixth book, of which it may be useful to give the algebraical signification. The first of these (the 27th) amounts to showing that $2x-x^2$ has its greatest value when $x=1$, and contains a limitation necessary to the conditions of the two which follow. The 28th proposition is a solution of the equation $ax-x^2=b$, upon a condition derived from the preceding proposition, namely, that $\frac{1}{4}a^2$ shall exceed b. It might appear more correct to say that the solution of this equation is one particular case of the proposition, namely, where the given parallelogram is a square; but nevertheless the assertion applies equally to all cases. Euclid however did not detect the *two* solutions of the question; though if the diagonal of a parallelogram in his construction be produced to meet the production of a line which it does not cut, the second solution may be readily obtained. This is a strong presumption against his having anything like algebra; since it is almost impossible to imagine that the propositions of the tenth book, deduced from any algebra, however imperfect, could have been put together without the discovery of the second root. The remaining proposition (the 29th) is equivalent to a solution of $ax+x^2=b$: but the case of $x^2-ax=b$ is wanting, which is another argument against Euclid having known any algebraical reasoning.

IRRAWADDI. [BIRMAN EMPIRE.]

IRREDUCIBLE CASE (that is, of cubic equations), the common name of a particular class of cubic equations, to which Cardan did not succeed in applying his celebrated rule. Bombelli however showed that the reason of this was the reality of all the three roots. The following is the sketch both of the method and the difficulty. [BOMBELLI; CARDAN; TARTALEA; THEORY OF EQUATIONS; NEGATIVE AND IMPOSSIBLE QUANTITIES.]

Unity has three cube roots, 1, $-\frac{1}{2}(1-\sqrt{-3})$, and $-\frac{1}{2}(1+\sqrt{-3})$, of which the product of the second and third is possible and equal to unity. Calling these 1, r, and r', it is next shown that a^3 has three cube roots, namely, a, ra, and $r'a$. Now, let there be a cubic equation (A, B, and C being possible quantities)

$$x^3+Ax^2+Bx+C=0;$$

and, by the method explained in INVOLUTION AND EVOLUTION, find another equation which has each root greater than a root of the preceding by $\frac{1}{3}$A. We have then

$$x^3+Px+Q=0\ \ldots\ (1)$$
$$P=B-\tfrac{1}{3}A^2 \qquad Q=C-\tfrac{1}{3}AB+\tfrac{2}{27}A^3.$$

Let x be $v+w$: then $x^3=v^3+w^3+3vwx$, and (1) becomes

$$v^3+w^3+(3vw+P)\,x+Q=0\ \ldots\ (2).$$

Determine v and w so that

$$3vw+P=0 \qquad v^3+w^3+Q=0;$$

by which means (2), and therefore (1), is satisfied. This gives

$$v^3\ (\text{or } w^3)=-\tfrac{1}{2}Q+\sqrt{(\tfrac{1}{4}Q^2+\tfrac{1}{27}P^3)}$$
$$w^3\ (\text{or } v^3)=-\tfrac{1}{2}Q-\sqrt{(\tfrac{1}{4}Q^2+\tfrac{1}{27}P^3)},$$

from which v and w can be found. But as each of the two, v and w^3, has three cube roots; and as no reason yet appears for choosing one rather than another, it should seem as if the possible combinations by which $v+w$ might be made would be nine in number. But on looking back we find the condition $3vw=-P$; so that the product of v and w must be a possible quantity. If then we signify by v and w the real cube roots of v^3 and w^3, the others are rv and $r'v$, rw and $r'w$; and the only combinations which satisfy the last-mentioned condition are

$$v+w,\quad rv+r'w,\quad r'v+rw,$$

which are the three roots of the equation (1), to the exclusion of $v+rw$, $rv+w$, $v+r'w$, $r'v+w$, $rv+rw$, $r'v+r'w$. So far all is right, and the algebraical solution is complete, and may be represented thus: let ρ stand for any cube root of unity; then the three solutions of (1) are contained in

$$\rho\,\sqrt[3]{(-\tfrac{1}{2}Q+\sqrt{(\tfrac{1}{4}Q^2+\tfrac{1}{27}P^3)})}$$
$$+\frac{1}{\rho}\sqrt[3]{(-\tfrac{1}{2}Q-\sqrt{(\tfrac{1}{4}Q^2+\tfrac{1}{27}P^3)})},$$

where $\sqrt[3]{\ }$ signifies the real cube root.

This is perfectly intelligible when $\frac{1}{4}Q^2+\frac{1}{27}P^3$ is a positive quantity: for if we call the real cube roots above mentioned K and L, we find for the three roots of the equation, first, the possible root, $K+L$; next, the pair of impossible roots contained in the formula

$$-\tfrac{1}{2}(K+L)\pm\tfrac{1}{2}(K-L)\sqrt{-3}.$$

If we apply this to the equation $x^3-9x-28=0$, where $P=-9$, and $Q=-28$, we shall find $K=3$, $L=1$, and the roots are 4, $-2+\sqrt{-3}$, and $-2-\sqrt{-3}$. But if it should happen that $\frac{1}{4}Q^2+\frac{1}{27}P^3$ is negative (which requires that P should be negative and $\frac{1}{27}P^3$ numerically greater than $\frac{1}{4}Q^2$), we return to the original form of the solution, and find that the roots of the equation are contained in the formula

$$\left\{V+W\sqrt{-1}\right\}^{\frac{1}{3}}+\left\{V-W\sqrt{-1}\right\}^{\frac{1}{3}}\ \ldots\ (3)$$

where $\{\ \}^{\frac{1}{3}}$ means any cube root, there being a tacit condition that the product of the two cube roots must be possible. V stands for $-\frac{1}{2}Q$, and W for the possible (though perhaps irrational) quantity $\sqrt{(-\frac{1}{4}Q^2-\frac{1}{27}P^3)}$. Now, it is shown in books of algebra that every cube root of $V+W\sqrt{-1}$ is of the same form, say $F+G\sqrt{-1}$, and that the corresponding cube root of $V-W\sqrt{-1}$ is $F-G\sqrt{-1}$. If then we assume

$$\left\{V+W\sqrt{-1}\right\}^{\frac{1}{3}}=F+G\sqrt{-1},$$
$$\left\{V-W\sqrt{-1}\right\}^{\frac{1}{3}}=F-G\sqrt{-1},$$

we find by multiplication

$$\left\{V^2+W^2\right\}^{\frac{1}{3}}=F^2+G^2;$$

and by addition of their cubes, and division by 2,

$$V=F^3-3FG^2,$$

between which the elimination of G gives

$$F^3 - \tfrac{3}{4} \sqrt[3]{V^2+W^2} \,.\, F - \tfrac{1}{4}V = 0;$$

from which it would seem that we might find F, and then G. But on examining this last equation we find it to be precisely that kind of cubic equation about which the difficulty arose; for the P of this equation is negative, being $-\frac{3}{4}\sqrt[3]{(V^2+W^2)}$, and the Q is $-\frac{1}{4}V$; and $\frac{1}{27}P^3$, being $-\frac{1}{64}(V^2+W^2)$, is numerically greater than $\frac{1}{4}Q^2$, or $\frac{1}{64}V^2$. Whence this case is called irreducible; for though, as will be shown immediately, there are three possible values of the expression (3), yet every direct algebraical attempt to find them leads to the same difficulty in another form.

If F and G could be determined, one value of (3) is 2 F; and taking the other cube roots, selecting only those pairs whose products are possible, we find

$$-\tfrac{1}{2}(1+\sqrt{-3})\ (F+G\sqrt{-1})\ -\tfrac{1}{2}(1-\sqrt{-3})\ (F-G\sqrt{-1})$$
$$-\tfrac{1}{2}(1-\sqrt{-3})\ (F+G\sqrt{-1})\ -\tfrac{1}{2}(1+\sqrt{-3})\ (F-G\sqrt{-1})$$

for the other admissible values. These may be reduced to

$$-F+G\sqrt{3}, \text{ and } -F-G\sqrt{3},$$

which are both possible. Consequently, the irreducible case of a cubic equation is that in which the three roots are all possible.

Let us apply the preceding to $x^3 - 21x + 20 = 0$. Here $P = -21$, $Q = 20$, $\frac{1}{4}Q^2 + \frac{1}{27}P^3 = -243 = -81 \times 3$. Hence the roots are contained in

$$\left\{-10+9\sqrt{3}\sqrt{-1}\right\}^{\frac{1}{3}} + \left\{-10-9\sqrt{3}\sqrt{-1}\right\}^{\frac{1}{3}}.$$

By trial (or by semi-tentative methods, described in most books of algebra) it may be found that a cube root of $-10+9\sqrt{3}\sqrt{-1}$ is $2+\sqrt{3}\sqrt{-1}$; whence $F=2$, $G=\sqrt{3}$. Hence one root (2 F) is 4; the second and third ($-F+G\sqrt{3}$ and $-F-G\sqrt{3}$), are $-2+3$ and $-2-3$, or 1 and -5.

But the best method of obtaining the roots is by having recourse to a registry of the roots of cubic equations, which is in the hands of every tyro, namely, the tables of sines and cosines, by which also the theorem of Bombelli will be established, namely, that the difficulty of the irreducible case answers to that of the trisection of an angle in geometry. It is proposed then, by means of trigonometry, to calculate the values of (3). Assume $V = r \cos.\theta$, $W = r \sin.\theta$, or find r and θ from

$$r = \sqrt{V^2+W^2}, \qquad \tan.\theta = \frac{W}{V}$$

in which that sign must be given to r, which gives $r \cos.\theta$ the sign of V. Then, by De Moivre's theorem [NEGATIVE AND IMPOSSIBLE QUANTITIES],

$$(\cos.\theta \pm \sin\theta\sqrt{-1})^{\frac{1}{3}} = \cos.\tfrac{1}{3}\theta \pm \sin.\tfrac{1}{3}\theta\sqrt{-1},$$

in which, by substituting $\theta+360°$ or $\theta+720°$ for θ, the equation $\tan.\theta = V \div W$ is still satisfied, and while the first side of the preceding equation is not altered in appearance, the different values of the cube root appear on the second side. From this we readily find that the expression (3) is no other than $2\sqrt[3]{r}\,.\cos.\frac{1}{3}\theta$; the three values of which, obtained as just noted, are

$$2\sqrt[3]{r}\,.\cos.\tfrac{1}{3}\theta,\ 2\sqrt[3]{r}\cos.(120°+\tfrac{1}{3}\theta),\ 2\sqrt[3]{r}\cos.(240°+\tfrac{1}{3}\theta)$$

which may be thus written:

$$2\sqrt[3]{r}\,.\cos.\tfrac{1}{3}\theta,\ -2\sqrt[3]{r}\,.\cos.(60°-\tfrac{1}{3}\theta),\ -2\sqrt[3]{r}\,.\cos.(60°+\tfrac{1}{3}\theta.)$$

Thus, in the preceding example, which gives $V=-10$, $W=9\sqrt{3}$, we find $r^2=100+243=343=7$; whence $\sqrt[3]{r} = -\sqrt{7}$. And $\tan.\theta = -\frac{9}{10}\sqrt{3}$, whence θ is found to be $-(57° 19' 16'')$, one-third of which is $-(19° 6' 25'')$, and this, with $79° 6' 25''$ and $40° 53' 35''$, are the angles on which the required values depend. The cosines of these angles, severally multiplied by $-2\sqrt{7}$, $2\sqrt{7}$, and $2\sqrt{7}$, give results as near to -5, 1, and 4 (the values found), as the unavoidable errors in the last places of logarithmic results, and the preceding rejection of fractions of seconds, will permit.

IRRIGATION. Of all the substances which concur in the vegetation and growth of plants water is the most essential: without moisture the seed cannot germinate, nor can the plant receive nourishment. Hence in warm climates, where rains are periodical, and where the soil is dried and parched by a continued evaporation, no verdure exists, except where springs or rivers supply the waste of moisture. The warmer the climate, and the more rapid the evaporation, the more luxuriant is the vegetation, provided there be an abundant supply of water. This circumstance has suggested the plan of diverting streams and conducting them in channels to fertilize as great an extent of land as possible. In China and in India, as well as in Egypt, ingenious modes of watering lands have been adopted from the most remote ages. No expense has been thought too great to secure a supply of water, and to distribute it in the most advantageous manner. It seems that where there is great heat in the air, water alone will supply the necessary food for the growth of plants. It is probable that the component parts of the atmosphere are more easily separated, and made to enter into new combinations with those of water, in a high temperature than in a lower; or that the leaves and green parts of vegetables imbibe water in a state of solution in air, and that in this state it is more easily decomposed. Atmospheric air and water contain all the principal elements of vegetables, viz. oxygen, hydrogen, carbon, and nitrogen: the remainder are either found in the soil or diffused through the water. Manures seem to act principally as stimulants or re-agents, and are themselves composed of the same elements: they are of no use unless diffused or dissolved in water; but when the water is impregnated with animal or vegetable substances, the effect is far greater and more rapid than when the water is pure.

Water has also an important office to perform, if we admit the principle discovered by Macaire, that plants reject through their roots those portions of the sap which are the residue of its elaboration, and which are of no further use to the plant, but rather injurious if they are again imbibed by the roots. Plants seem to require a removal of their excrements, as animals do when tied up in stalls, or confined in a small space. If this is not effected, they suffer and contract diseases. The percolation of water through the soil is the means which nature has provided for this purpose. Hence we can readily suppose that the mere washing of the roots has a beneficial effect, and to this in a great measure must be ascribed the fertilizing effects of pure and soft running water.

If water stagnates and is evaporated, and the noxious matter held in solution remains in the soil, all the advantage of irrigation is lost, and the better kinds of grasses are succeeded by rushes and coarse aquatic plants, as may be seen in all marshy spots. The circulation of the water therefore appears to be as necessary as its presence; and, provided there be a sufficient supply of water of a proper quality, the more porous the soil, and especially the subsoil, is, the more vigorous is the vegetation. It is on this principle alone that we can rationally account for the great advantage of irrigation in those climates where rain is abundant, and where the soil, which is most benefited by having a supply of water running through it, is of a nature to require artificial draining as an indispensable preliminary to being made fertile by irrigation. By keeping these principles in view great light will be thrown on the practical part of irrigation, which, having been long established by experience before these principles were thought of, depends not on their correctness, but only confirms their truth.

The whole art of irrigation may be deduced from two simple rules, which are, first, to give a sufficient supply of water during all the time the plants are growing, and secondly, never to allow it to accumulate so long as to stagnate. We shall see hereafter one apparent exception to this last rule, but it will be readily explained.

The supply of water must come from natural lakes and rivers, or from artificial wells and ponds, in which it is collected in sufficient quantity to disperse it over a certain surface. As the water must flow over the land, or in channels through it, the supply must be above the level of the land to be irrigated. This is generally the principal object to be considered. If no water can be conducted to a reservoir above the level of the land, it cannot be irrigated. But there must also be a ready exit for the water, and therefore the land must not be so low as the natural level of the common receptacle of the waters, whether it be a lake or the sea, to which they run. The taking of the level is therefore the first step towards an attempt to irrigate any lands.

Along the banks of running streams nature points out the declivity. A channel, which receives the water at a point higher than that to which the river flows, may be dug with a much smaller declivity than that of the bed of the river, and made to carry the water much higher than the natural banks. It may thence be distributed so as to descend slowly and water a considerable extent of ground in its way to rejoin the stream. This is by far the most common mode of irrigation, and the shape, size, and direction

of the channels are regulated by the nature of the surface and other circumstances, which vary in almost every situation. A few examples will give to those who are not acquainted with the best modes of irrigating land a pretty accurate notion of the system.

We shall suppose a river to run with a rapid current between high banks. At some point of its course a portion of the water is diverted into a canal dug along the bank, with a very small declivity. The water in this canal will flow with less rapidity than the river, but will keep the same level as that part of the river where it has its origin. Thus the water may be carried over lands which are situated considerably above the bed of the river farther down. All the lands between this canal and the river may be irrigated if there is a sufficient supply of water. The canal may be carried to a considerable distance from the river. The size of the canal and its declivity depend on the quantity of water which may be made to flow into it. A dam is often constructed across a river, in order that as much of its water as is possible may be diverted, and the original channel is often laid quite dry, to take advantage of all the water at the time when it is advantageous to irrigate the land. To have an entire command of the water there are flood-gates on the main channel and on the lesser branches. By opening or shutting these the water may be stopped or made to flow as may be required. It must be remembered, that to carry water to a considerable distance, and in great quantity, a larger channel and more rapid declivity are required; and it is a matter of calculation whether it is most advantageous to bring a smaller quantity to a higher point, or a greater abundance somewhat lower. Having a certain command of water, it may be carried from the main channel by smaller branches to different points, so as to irrigate the whole equally. These branches should be nearly horizontal, that the water may overflow the sides of them, and be equally distributed over the land immediately below. Every branch which brings water over the land should have a corresponding channel below to carry it off; for the water must never be allowed to stop and stagnate. When it has run 15 or 20 feet, according to the declivity, over the land situated below the *feeder*, or the channel which brings the water, it should be collected into a drain to be carried off, unless it can be used to irrigate lands which lie still lower. Finally it runs back into the river from which it was taken, at a lower point of its course.

When there is a considerable fall and a sufficient supply of water, a series of channels may be made, so situated below each other, that the second collects the water which the first has supplied, and in its turn becomes a feeder to irrigate the lower parts of the declivity: a third channel receives the water and distributes it lower down, until the last pours it into the river. This is called *catch work*, because the water is caught from one channel to another. This method is only applicable where there is a considerable fall of water and a gentle declivity towards the river. But it must be borne in mind that the water is deteriorated for the purpose of irrigation, when it has passed over the land, and that it is not advantageous to let it flow over a great extent when a fresh supply can be obtained: but where only a small portion of water can be commanded, that must be made the most of; and it will irrigate three or four portions of land in succession without there being any very marked difference in the effect: beyond this it rapidly loses its fertilizing qualities. This is not owing to the water having deposited the fertilizing substances which it held in solution, or which were diffused through it, but it is owing to its having taken up some which are detrimental to vegetation, and being saturated with them: at least this is the most probable opinion when all circumstances are taken into the account.

The general principle of irrigation may be described as the supplying every portion of the surface with an abundance of water, and taking it off again rapidly. In many situations the great difficulty in irrigation arises from the want of a supply of water; but even then a partial irrigation may be effected, which, although not perfect, will have its advantages. A small rill which is often quite dry in summer may still, by judicious management, be made to improve a considerable portion of land: its waters may be collected and allowed to accumulate in a pond or reservoir, and let out occasionally, so that none be lost or run to waste. If there is but a small quantity it must be husbanded and made to flow over as great a surface as possible. If there is water only at particular seasons of the year, and at a time when it would not be of much use to the land, it may be kept in ponds, and it will lose none of its qualities by being exposed to the air. If animal or vegetable matter in a partial state of decomposition is added to this water, it will much improve its quality, and by a judicious distribution of it over the land a great benefit may be obtained.

If there is not a want of water, there may be a want of declivity to enable it to flow off, which, it should always be remembered, is an essential part of irrigation. Art may in this case assist nature by forming a passage for the water, either in its course towards the land to be irrigated, or from it after it has effected its purpose. Where there is no natural exit, and it might lead to too great an expense to make an artificial one, the water may sometimes be led into shallow ponds, where a great part is evaporated; or porous strata may be found by boring, into which it can be made to run and be dispersed. Along rivers where the fall is very imperceptible a channel brought from a considerable distance may give such a command as to throw the water over a great extent of surface; and to carry it off another channel may be cut, emptying itself at some distance below: so that lands which lie along the banks of a river may be irrigated, although they are actually below the level of the river, and require banks to protect them from inundation.

When the surface to be irrigated is very flat and nearly level, it is necessary to form artificial slopes for the water to run over. The whole of the ground is laid in broad beds, undulating like the waves of the sea. The upper part of these beds is quite level from end to end, and here the channel or float which brings the water on is cut. From the edge of this channel the ground is made to slope a foot or two on both sides, and a ditch is cut at the bottom parallel to the float. The whole of the ground is laid out in these beds. All the floats are supplied by a main channel at right angles to the beds, and somewhat above them, and all the ditches or drains run into a main ditch parallel to the main float, and below the lowest drain. The course of the water is very regular. As soon as the flood gates are opened it flows into all the upper channels, which it fills till they overflow in their whole length. The sloping sides are covered with a thin sheet of running water, which the lower drains collect and carry into the main ditch.

Experience has shown that there are particular seasons when the water has the best effect; a perfect command of it is therefore indispensable, and also a regular supply. During frost, when all dry meadows are in a state of torpor, and the vegetation is suspended, the water-meadows, having a current of water continually flowing over them, are protected from the effect of frost, and the grass will continue to grow as long as the water flows over it. Too much moisture however would be injurious, and the meadows are therefore laid dry by shutting the flood-gates, whenever the temperature of the air is above freezing. By this management the grass grows rapidly at the first sign of spring. Before the dry upland meadows have recovered the effects of frost and begun to vegetate, the herbage of the water-meadows is already luxuriant. As soon as they are fed off or cut for the first crop of hay, the water is immediately put on again, but for a shorter time; for the warmer the air, the less time will the grass bear to be covered with water. A renewed growth soon appears, and the grass is ready to be cut a second time when the dry meadows only give their first crop. Thus, by judicious management, three or four crops of grass are obtained in each season, or only one abundant crop is made into hay, and the sheep and cattle feed off the others. The usual way in which the grass of water-meadows is made profitable is by feeding ewes which have early lambs till the middle of April. A short flooding soon reproduces a crop, which is mown for hay in June; another flooding gives an abundant aftermath, which is either mown for hay, or fed off by cows, bullocks, and horses; for at this time the sheep, if pastured in water-meadows, are very subject to the rot. The value of good water-meadows could scarcely be believed by those who are not familiar with them. Where the water is suited to irrigation they never require manuring. Their fertility is kept up continually, and the only attention required is to weed out coarse aquatic plants, which are neither nutritious nor wholesome in hay or pasture.

The best soil for a water-meadow is a good gravel. The finest water-meadows on the Avon in Wiltshire, where the richest herbage is found, have scarcely any soil at all, but are on a bed of shingle and pebbles matted together by the

roots of the grass, which proves to demonstration that the waters of the Avon contain all the principles essential to rapid vegetation. Great attention is required, and some experience, to irrigate meadows, so as to give the greatest profit.

In hot weather, when we should imagine that the land must be thirsty, and that too much water cannot be poured over it, much mischief may be done by injudicious flooding. In winter, on the contrary, the land may be covered with water for weeks without injury; and if an earthy deposit takes place, the subsequent fertility is greatly increased. But this is not properly irrigation: it is inundation, and the effects depend on entirely different causes. When low meadows are inundated in winter and spring, it is the muddiness of the water which enriches the land: a fine layer of extremely divided matter is deposited, and when the water subsides this acts as a coat of manure.

Water may be carried in small channels through meadows without being allowed to overflow, and in this case the effect is similar to that caused by rivers or brooks which wind slowly through valleys, and produce a rich verdure along their course. This is watering, but not properly irrigating. When this is done judiciously, the effect is very nearly the same as when the land is irrigated; and in hot climates it may be preferable, by giving a constant supply of moisture to the roots, while the plants are growing. The great advantage of water-meadows in England is not so much the superior quantity of grass or hay which is obtained when they are mown, as the early feed in spring, when all kinds of nutritive fodder are scarce; when the turnips are consumed before the natural grass or the rye sown for that purpose is fit to be fed off, the water-meadows afford abundant pasture to ewes and lambs, which by this means are brought to an early market. The farmer who has water-meadows can put his ewes earlier to the ram, without fear of wanting food for them and their lambs in March, which is the most trying season of the year for those who have sheep. At that time an acre of good grass may be worth as much for a month as a later crop would for the remainder of the year. When it is intended to form a water-meadow on a surface which is nearly level, or where a fall of only two or three feet can be obtained in a considerable length, the whole of the land must be laid in beds about 20 or 30 feet wide, the middle or crown of these beds being on a level with the main feeders, and the bottoms or drains on a level with the lower exit of the water, or a little above it. To form these beds most expeditiously, if the ground is already in grass, the sod may be paired off and relaid after the beds are formed, by which means the grass will be sooner re-established; but except in very heavy soils, where the grass is some time in taking root, the easiest and cheapest way is to plough the land two or three times towards the centre, and dig out the drain with the spade: the earth out of the drains, and that which is taken out of the upper trench or feeder, may be spread over the bed to give it the proper slope. A roller passed over the bed in the direction of its length will lay it even, and the seeds of grasses being sown over it, the water may be let on for a very short time to make them spring. As soon as the grass is two or three inches above ground a regular flooding may be given, and in a very short time the sward will be complete. Instead of sowing seed, tufts of grass cut from old sward may be spread over the newly formed beds, and they will soon cover the ground. The Italian rye-grass, which has been lately introduced into this country from Lombardy and Switzerland, grows so rapidly, that if it be sown in February, or as soon as the snow and frost are gone, it will afford a good crop to feed off in April, or to mow for hay by the beginning of May; and after that it may be cut repeatedly during the summer. But where the soil is good and the water abundant, good natural grasses will spring up without much sowing, and soon equal the old water-meadows.

It seems essential to the formation of a good water-meadow that the bottom be porous and free from stagnant water; hence under-draining is often indispensable before a water-meadow can be established; and a peat-bog, if drained and consolidated, may have water carried over its surface, and produce very good herbage. If the soil is a very stiff clay, draining is almost indispensable where a water-meadow is to be made. The more porous the soil the less depth of water is required, which is not obvious at first sight; but the clay lets the water run over the surface without soaking into the roots, whereas the porous soil is soon soaked to a considerable depth. The water must therefore be longer on the clay than on the sand or gravel to produce the same effect. If the water is properly applied all kinds of soils may be converted into fertile water-meadows. On very stiff clays a coat of sand or gravel, where it can be easily put on, will greatly improve the herbage. It should not be ploughed in, but laid on the surface two or three inches thick: chalk will also improve the herbage.

The usual time of letting on the water on water-meadows is just before Christmas, and it may continue to flow over the land as long as the frost lasts: in mild weather it may be turned off during the day and put on again at night until the frost is gone. The grass will soon begin to grow, and be ready to be fed off. When this is done the water is immediately let on for a short time, and turned off again to allow the ground to dry after a few days' flooding, and the water is let on again at short intervals. The warmer the air is, the shorter time must the water be allowed to cover the meadows. As soon as the grass is five or six inches long it must be left dry entirely till it is mown or fed off. In summer the floodings must be very short; seldom more than twenty-four hours at a time, but frequent. Thus a great weight of grass may be obtained year after year without any manure being put on the land, care being taken that where the surface is not quite even the hollows be filled up with earth brought from another place, or dug out of the drain, if that should be partially filled up with the soil which the water has carried into it. We alluded before to a case where water may remain a considerable time on the land without injury; this is, when there are inundations from rivers, which rise above their beds in spring and cover the low meadows which lie along their

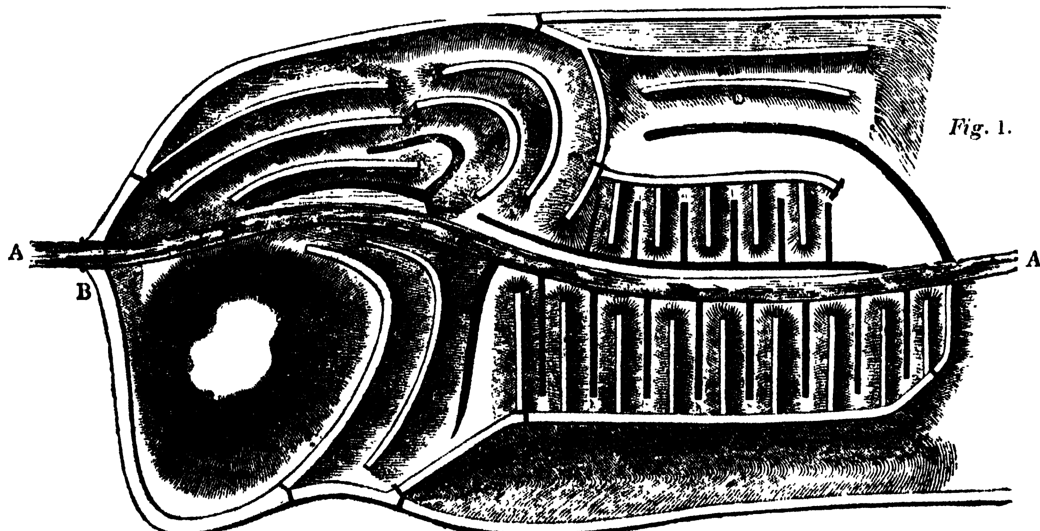

Fig. 1.

banks. In this case the grass, which has not yet sprung up, is protected from the cold, and if there is a deposit from the water there is a considerable advantage. But when it subsides, it must be made to run off entirely, without leaving small pools, by which the grass would invariably be injured. Small ditches or channels are usually dug, by which all the water may run off, unless where the subsoil is very porous, or the land is well under-drained, which is seldom the case in these low meadows, for the drains would be apt to be choaked by the earthy deposit from the water. These inundations can sometimes be regulated by means of dykes and flood-gates, in which case they partake of the advantages of irrigation, and also of that deposition of fertilizing mud which is called warping. [WARPING.]

The preceding plan (*fig.* 1) will explain what has been briefly said respecting the different modes of irrigating land. A A is a river which has a considerable fall, and then flows through a level plain. A considerable channel is cut at B, where there is a rapid fall over a natural or artificial dam. This channel is carried round a hill and supplies a series of channels, C, C, C, placed below each other, forming catch-work along a declivity. A portion of the water goes on to D, where it supplies the feeders of a regular set of ridges, or beds, made as before described, from which the water returns into the river by a main trench, into which all the drains run.

On the other side of the river, where the slopes lie somewhat differently, there are several examples of catch-work, the black lines representing the drains which receive the water after it has flowed over the surface and carry it into the river below. It is evident that all the feeders are nearly horizontal, to allow the water to flow over their sides.

IRRITABILITY. [HALLER.]

IRTISCH. [SIBERIA.]

IRVINE, a royal borough and seaport town in the district of Cunningham and county of Ayr, 68 miles southwest by west from Edinburgh. It is situated on a rising ground to the north of the river Irvine, and about half a mile distant from the harbour, which lies to the south-west of it. The town is dry and well aired, and consists of one broad street, which communicates with the southern suburb by means of a narrow stone bridge of four arches, rebuilt in the year 1826. The principal public buildings are the church and town-house. The harbour is commodious, having from nine to eleven feet water on the bar at spring-tides; though during violent gales from the south it rises to sixteen feet. The rapid growth of Kilmarnock has tended greatly to increase the trade of Irvine, which is the nearest seaport to that town. The dues levied at the port during the five years preceding 1832 averaged 450*l.* per annum. Ship-building is carried on upon a small scale. Irvine, in union with Rothsay, Inverary, Campbelltown, and Ayr, returns one member to parliament. The school, wherein Greek, Latin, French, and the mathematics are taught, is ably conducted by the rector and an English assistant. The population of the burgh and parish of Irvine in 1831 was 5200. (Carlisle's *Dictionary*; *Beauties of Scotland*; *Population Returns*, &c.)

ISABELLA of CASTILE. [COLUMBUS; FERDINAND V.]

ISÆUS, one of the ten Athenian orators, was a native of Chalcis, or, according to other accounts, of Athens. Dionysius could not ascertain the time of his birth or death. So much as this appears certain: the vigour of his talent belonged to the period after the Peloponnesian war, and he lived to see the time of king Philip. Hermippus, who wrote the lives of the pupils of Isocrates, has recorded nothing more of Isæus than that he was a pupil of Isocrates, instructed Demosthenes, and enjoyed the society of the chief philosophers of his time.

The author of the Life of Isæus, attributed to Plutarch, mentions sixty-four orations of Isæus, fifty of which were allowed to be genuine. At present there are only eleven extant, all of which are of the forensic class (λόγοι δικανικοί), and all treat of matters relating to wills and the succession to the property of testators, or persons intestate, or to disputes originating in such matters. These orations are valuable for the insight which they give us into the laws of Athens as to the disposition of property by will, and in cases of intestacy, and also as to many of the forms of procedure. Dionysius, in his laboured comparison between Lysias and Isæus, sums up as follows:—'In reading Lysias one would not suppose that any thing is said either in an artificial manner or without perfect sincerity, but everything appears natural and true; thus forgetting that it is the height of art to imitate nature. In reading Isæus one has just the contrary feeling; nothing appears to be spoken naturally and without an effort, not even what really is so spoken; but everything seems of set purpose, framed to deceive, or for some other sinister end. One would believe Lysias, though he were stating what was false; one cannot, without some feeling of distrust, assent to Isæus, even when he speaks the truth.' Again:—'Lysias seems to aim at truth, but Isæus to follow art: the one strives to please, the other to produce effect.'

Dionysius adds that, in his opinion, with Isæus originated that vigour and energy of style (δεινότης) which his pupil Demosthenes carried to perfection. So far as the extant specimens of Isæus enable us to form an opinion, this judgment appears to be just. The perspicuity and the artless simplicity of the style of Lysias are admirable; but on reading Isæus we feel that we have to do with a subtle disputant and a close reasoner, whose arguments are strong and pointed, but have too much the appearance of studied effect, and for that reason often fail to convince.

The best edition of the text of Isæus is by Bekker. The oration on the 'Inheritance of Menecles' was first published by Tyrwhitt, London, 1785; and that on the 'Inheritance of Cleonymus' first appeared in its complete form at Milan, 1815, by Ang. Mai. The translation of Isæus by Sir William Jones (1779, 4to.) will give an English reader a sufficient notion of this orator; but the translation is somewhat deficient in critical accuracy, and also wanting in force.

ISAIAH (יְשַׁעְיָהוּ, LXX. 'Ησαΐας), one of the most celebrated of the Hebrew prophets, lived during the reigns of Uzziah, Jotham, Ahaz, and Hezekiah (*Is.* i. 1; vii. 1; xiv. 28; xxii.; xxxvi.—xxxviii.), and was contemporary with the prophets Amos, Hosea, Joel, and Micah. We possess no particulars in the Old Testament respecting the place of his birth or his history; but we learn from the inscription of the book that he was the son of Amoz, who was, according to one Jewish tradition, the brother of Amaziah, king of Judah; but according to another was considered to be the same person as the prophet Amos. The latter tradition is evidently wrong; since the name of the prophet is עָמוֹס, while the name of the father of Isaiah is אָמוֹץ. It is probable, from the 6th chapter of the book, that Isaiah entered upon his prophetical office in the last year of the reign of king Uzziah, B.C. 759. He continued to prophesy at least till the fourteenth year of the reign of Hezekiah, B.C. 713 (2 *Kings*, xix. 2-7; *Is.* xxxvi.—xxxviii.), a period of forty-six years. According to an antient Jewish tradition, which is also given in the apocryphal book of the 'Ascension of

Isaiah,' he was put to death during the reign of the cruel Manasseh (2 *Kings*, xxi. 16); who is said by Josephus (*Antiq.*, x. 3, § 1) to have slain all the prophets in Jerusalem. Manasseh commenced his reign B.C. 697; and Isaiah must therefore have continued to prophesy for sixty-two years at least, if this tradition is correct. Isaiah had a greater influence in public affairs than any other prophet, except Elijah and Elisha. He appears to have been the intimate friend of Hezekiah; and it was principally owing to his advice and firmness that the army of Sennacherib was defeated.

The prophecies of Isaiah consist of sixty-six chapters, all of which were considered, till within the last thirty or forty years, to have been composed by the prophet himself. But it is the common opinion of the critics in Germany usually called Rationalists, that the book of Isaiah is a collection of prophecies delivered by different persons, which were collected and arranged in their present form during the Babylonian exile. The whole of the latter part of the book, from ch. xl. to ch. lxvi., is supposed to have been written at Babylon during the exile, and a considerable part of the first thirty-nine chapters is attributed to other authors than Isaiah. Some critics have called the book a 'poetical anthology.' This opinion was first maintained by Koppe, and has been supported by Döderlein, Justi, Eichhorn, Bauer, Paulus, Rosenmüller, Bertholdt, De Wette, Augusti, and at great length by Gesenius in his translation of Isaiah, Leip., 1821-9. The best arguments in defence of the common opinion are given by Jahn in his 'Introduction to the Bible,' by Professor Lee in his 'Sermons and Dissertations on the Study of the Scriptures,' and by Hengstenberg in his 'Christologie des alten Testaments,' Berl., 1829-35.

If we admit Isaiah to have been the author of the book which bears his name, it is nearly certain that the prophecies are not arranged at present in the order in which they were delivered. The sixth chapter apparently contains an account of the inauguration of the prophet in his sacred office, and appears to have been the first prophecy that was published by him. The twenty-second chapter consists of two separate parts which have no connexion with each other, and were probably published at different times; the former half of the chapter (1-14) containing a prediction of the invasion of the Medes and Persians, while the latter half gives an account of the disgrace of a courtier of the name of Shebna during the reign of Hezekiah. It is therefore difficult to give any connected account of the contents of the book; but the following arrangement, taken from Gesenius, is perhaps the best upon the whole.

The first part (i.—xii.) principally consists of prophecies relating immediately to the Jewish people; the second part (xiii.—xxiii.) contains predictions against the Babylonians, Assyrians, Philistines, Moabites, Syrians, Egyptians, and other foreign orations; the third part (xxiv.—xxxv.), with an historical appendix (xxxvi.—xxxviii.) containing an account of the invasion of Sennacherib, contains prophecies of the invasion of Judæa by the Babylonians, of the destruction of Jerusalem, the captivity of the people, and their final restoration to their native country; the fourth part (xl.—lxvi.) principally refers to the restoration of the church; it contains many prophecies respecting the deliverance of the Jews from captivity, the destruction of idols, the spread of the true religion over the earth, the conversion of the Gentiles, and the coming of the Messiah.

The prophecies of Isaiah have always been held in great veneration by the Jews. Jesus, the son of Sirach, speaks of Isaiah as 'a prophet great and faithful in his vision, who saw by an excellent spirit what should come to pass at the last, and comforted them that mourned in Sion. He showed what should come to pass for ever, and secret things before they came.' (*Ecclesiasticus*, xlviii. 22-25.) Josephus and Philo frequently speak of Isaiah in terms of the greatest respect; and his prophecies are constantly quoted by the writers of the New Testament. See *Matt.* i. 22, 23, compared with *Is.* vii. 14; *Matt.* iii. 3, with *Is.* xl. 3; *Matt.* iv. 14-16, with *Is.* ix. 1, 2; xlii. 7; *Matt.* viii. 17, with *Is.* liii. 4; *Matt.* xiii. 14, 15, with *Is.* vi. 9, 10; *Matt.* xxi. 13, with *Is.* lvi. 7; *Luke*, iv. 17-19, with *Is.* lxi. 1-3; *Acts*, xiii. 34, with *Is.* lv. 3; *Acts*, xxviii. 25-27, with *Is.* vi. 9, 10; *Rom.* ix. 27, 28, with *Is.* x. 22; *Rom.* ix. 29, with *Is.* i. 9; *Rom.* ix. 33, with *Is.* viii. 14; *Rom.* x. 16, with *Is.* liii. 1; *Rom.* x. 20, 21, with *Is.* lxv. 1, 2; 1 *Cor.* i. 19, 20, with *Is.* xliv. 25; 2 *Peter*, iii. 13, with *Is.* lxv. 17.

A considerable part of the prophecies of Isaiah are supposed by most Christian divines to relate to the Messiah. The following list is taken from Gray's 'Key to the Old Testament,' pp. 369, 370: the divine character of Christ (vii. 14; ix. 6; xxxv. 4; xl. 5, 9, 10; xlii. 6-8; lxi. 1; lxii. 11; lxiii. 1-4); his miracles (xxxv. 5, 6); his peculiar qualities and virtues (ix. 2, 3; xl. 11; xlii. 1-3); his rejection (vi. 9-12; viii. 14, 15; liii. 3); his sufferings for the sins of man (liii. 4-11); his death, burial (liii. 8, 9), and victory over death (xxxv. 8; liii. 10-12); his final glory (xlix. 7, 22, 23; lii. 13-15; liii. 4, 5), and the establishment, increase (ii. 2-4; ix. 7; xlii. 4; xlvi. 13), and perfection (ix. 2-7; xi. 4-10; xvi. 5; xxix. 18-24; xxxii. 1; xl. 4, 5; xlix. 9-13; li. 3-6; lii. 6-10; lv. 1-3; lix. 16-21; lx.; lxi. 1-5; lxv. 25) of his kingdom. The number of Isaiah's prophecies relating to the Messiah was thought by Jerome to be so numerous and important, that he says, in his preface to the book, that Isaiah ought rather to be called an Evangelist than a prophet; and many modern commentators give him the title of the Evangelical Prophet.

The style of Isaiah is said by Lowth (*Prælect.* xxi) 'to abound in such transcendent excellencies, that he may be properly said to afford the most perfect model of the prophetic poetry. He is at once elegant and sublime, forcible and ornamented; he unites energy with copiousness, and dignity with variety. In his sentiments there is uncommon elevation and majesty; in his imagery the utmost propriety, elegance, dignity, and diversity; in his language, uncommon beauty and energy; and notwithstanding the obscurity of his subjects, a surprising degree of clearness and simplicity. To these we may add that there is such sweetness in the poetical composition of his sentences, whether it proceed from art or genius, that if the Hebrew poetry at present is possessed of any remains of its native grace and harmony, we shall chiefly find them in the writings of Isaiah.'

In addition to the book of prophecies, Isaiah is also said to have written the lives of Uzziah (2 *Chron.* xxvi. 22) and Hezekiah (2 *Chron.* xxxii. 32). The former work is entirely lost: but we probably possess the greater part, if not the whole, of the latter in chapters xxxvi.—xxxviii. of his prophecies.

We learn from the Fathers that several apocryphal works [APOCALYPSE], which were in circulation in the early ages of the Christian æra, were attributed to Isaiah. An Ethiopic translation of one of these works, entitled the 'Ascension of Isaiah,' which was originally written in Greek and is quoted by Epiphanius (*Hæres.* xl. 2) and Jerome (*Commentary upon Is.* lxiv. 4), was published for the first time by Dr. Laurence, Oxf. 1819, 8vo. This work contains an account of the prophet's ascension through the firmament and the six heavens into the seventh, and also of his martyrdom during the reign of Manasseh.

(The Introductions of Eichhorn, Jahn, De Wette, Augusti, and Horne; Vitringa, *Commentarius in Librum Proph. Isaiæ*, 2 vols. fol. 1714-1720; Lowth's *Isaiah*, Lond. 1778, frequently reprinted; there is a good German translation of this work with many additions by Koppe, 4 vols. 1779-1781; Döderlein's *Esaias*, 8vo., 3rd ed., 1789, with excellent notes; Rosenmüller's *Scholia*; Gesenius, *Der Prophet Jesaia, übersetzt und mit einem vollständigen philologisch-critischen und historischen Commentar begleitet*, Leip. 1821-9, the best translation and commentary that has yet appeared.)

IS'CHIA, the antient Ænaria, an island situated at the northern entrance of the Bay of Naples, the smaller island of Procida lying between it and the promontory of Misenum on the mainland. Procida (Prochyta), according to an old tradition, was rent from Ischia by an earthquake. The island is mountainous; the highest summit, called Mount Epomeo, which is an extinct volcano, rises about 2500 feet above the sea, and has near its summit distinct traces of two very large craters. The volcanic district of Naples is considered to comprise not only Vesuvius, with Pozzuoli and Cumæ, but also the islands of Procida and Ischia. The last eruption of the Epomeo was in 1301, when a broad stream of lava ran over the eastern part of the island, for nearly two miles, as far as the sea. Strabo calls this island by the name of Pithecusæ, which is not, as Pliny observes, derived from pithécus (an ape), but from a word of similar form, which signifies an earthen vessel. The clay of the island, it seems, has been used for earthenware from the remotest time. The island was settled by Greeks of Chalcis and Eretria. There were numerous traditions of volcanic

action having taken place in this island; and Timæus mentions a violent eruption of Epomeo a little before his time. The soil of Ischia is very fertile, and produces corn, abundance of wines, and all sorts of fruit. The hills are covered with chesnut trees. The island is about twenty miles in circuit, and contains 24,000 inhabitants, who have a reputation for good behaviour much above that of their neighbours of the mainland. Robbery and murder are very rare in the island, and the houses are frequently left by the owners with the door merely on the latch without any suspicion or fear. The people are industrious, very frugal, and good tempered. Ischia forms part of the province of Naples; it contains four small towns or villages: 1. Ischia, which is a bishop's see and has a castle; 2. Foria, which is the most commercial place on the island; 3. Casamicciola, the neighbourhood of which contains excellent clay, of which a great quantity of pottery is made and sent to Naples; 4. Lacco: besides several hamlets. The island abounds with mineral springs, which are much frequented by invalids from Naples, and are found efficacious for curing several distempers. Ischia is altogether one of the finest islands near the coast of Italy. (De Quintis, *Inarime, seu de Balneis Pithecusarum, libri vi.*, 8vo., Naples, 1726; G. Poulett Scrope, *On the Volcanic District of Naples*, in *Geolog. Trans.*, second series, vol. ii.; Strabo, *Casaub.*, p. 248; Plin., *Nat. Hist.*, ii. 88, iii. 6.)

ISEGHEM, a market-town in the province of West Flanders. The population of the town is 2100, and that of the parish about 7000 inhabitants. The inhabitants manufacture considerable quantities of linen and tape. It is nine miles north by west of Courtray, and twenty miles south of Bruges.

ISER. [BAVARIA.]

ISE'RE, a river in the south-eastern part of France, belonging to the system of the Rhône. It has its source near Mont Iseran (13,262 feet high), in the chain of the Pennine Alps in Savoy. It flows 20 miles north-west to St. Maurice, and then 15 miles south-west to Moutiers or Moutier; from Moutiers it turns again to the north-west and flows 12 miles to Conflans, the most northern point of its course; and again turning south-west, flows 22 miles to Montmeillan, where its navigation commences. In the upper part of its course it receives some small tributaries, the combined streams of the Darou and the St. Jean at Moutiers; the combined streams of the Arli and Doron at Conflans; and between Conflans and Montmeillan, the Arc, an alpine stream 68 miles long, which passes St. Jean de Maurienne. Just below Montmeillan the Isère turns to the south, crosses the French frontier, gradually bends to the south-west and west, passes Grenoble, dividing that town into two parts, and unites with the Drac, its most important tributary. From the junction of the Drac the Isère flows north-west for a short distance, and then turning to the south-west, flows past St. Marcellin and Romans into the Rhône, which it joins between Tournon and Valence. The length of the navigable part of the Isère below Montmeillan is about 90 miles: its whole course is about 160 miles.

The Drac rises in the department of Hautes Alpes, and has a course of 72 or 73 miles. It receives the Sevrayes, the Bonne, the Romanche, and other streams.

The Isère is of moderate breadth, but of great depth. Its waters are of a blackish colour, which is attributed by some to the débris of the slate rocks of the Tarentaise, a district in Savoy, through which it flows. The stream is liable to inundations, which cause the most disastrous effects. It is used for floating timber from Moutiers, 34 miles above Montmeillan. Between the last-mentioned town and Grenoble the navigation is very difficult, on account of the great number of islets in the bed of the river. Iron, hemp, linen and woollen cloth, and wood are carried down the stream. Barges laden with salt and other merchandise ascend it from the Rhône to Grenoble and Montmeillan.

ISE'RE, a department of France, taking its name from the river above mentioned. It is bounded on the north by the department of Ain, from which it is separated by the Rhône; on the west by the departments of Rhône, Haute Loire, and Ardèche, from which also it is separated by the Rhône; on the south-west and south by the department of Drôme; and on the south-east by that of Hautes Alpes: on the east and north-east it is bounded by the duchy of Savoy, part of the dominions of the king of Sardinia. Its form, though irregular, approximates to that of a parallelogram; having its sides facing the north-east, south-east, south-west, and north-west respectively. Its greatest length is from the north-west, on the banks of the Rhône, near Lyon, to the south-east, not far from Briançon, in the department of Hautes Alpes, 92 miles; its greatest breadth at right angles to the length is from near the little town of Allevard, amid the Alps, to the bank of the Isère, below St. Marcellin, 55 miles. Its area is 3205 square miles, which is considerably above the average area of the French departments, and above the area of any English county except Yorkshire; it is about equal to the conjoint areas of Shropshire, Staffordshire, and Worcestershire. The population by the census of 1831 was 550,258; by that of 1836, 573,645; showing an increase in five years of above 23,000 in a population of more than half a million. The census of 1836 gives 179 inhabitants to a square mile, which is above the average density of population in France, but very far below that of the above-mentioned English counties. Grenoble, the capital, is on the banks of the Isère, in 45° 11′ N. lat., and 5° 43′ E. long.

Nearly the whole of this department is covered with mountains. A branch of the Alps, which joins the principal chain between Mont Genèvre and Mont Cenis, and extends to the Rhône, forms the boundary between this department and the Sardinian dominions. In this branch or in its subordinate ramifications are the summits, Mont Trois Ellions, 12,737 feet high; Col de Saix, 10,971 feet; Pic de Belladone, 10,229 feet; La Roche Grenico, 9973 feet; Sept Laux (upper summit), 9743 feet; and the Col du Galibier, 9154 feet. Some of the summits of this mountainous tract are covered with perpetual snow, and enclose glaciers. The mountains are traversed by narrow passes, and the slopes and precipices are covered with dark forests. Mountain streams tumble from rock to rock, or pass rapidly through deep glens. Grottos with stalactites are common in the mountains: that of La Balme was counted among the wonders of Dauphiné. [BALME, LA.] Some of the valleys are of tolerable width and of great beauty, as that of Grésivaudan, watered by the Isère; but there are no plains except in the northern and western parts towards the banks of the Rhône. The whole department is comprehended in the basin of the Rhône.

The chief rivers are the Rhône, which borders the department on the north and west. The Guiers, formed by the junction of two streams, the Guiers Vif and the Guiers Mort, skirts the north-eastern boundary, and joins the Rhône on its left bank at the point where the latter first touches the department. A number of small streams, which successively fall into the Rhône on its left bank, water the more level districts of the north-west. The Isère crosses the department in the direction of its breadth, watering the valley of Grésivaudan: its junction with the Rhône is in the adjacent department of Drôme. The Drac has the greater part of its course in this department.

In the alpine country are many lakes; the principal is that of Paladru, near the head of the Fure, which runs through the lake. There are also several marshes.

The mountains east of the junction of the Isère and the Drac consist of granitic and other primitive rocks. To the north and west of this district, extending to the banks of the Bourbre and the junction of that river with the Rhône, and to the lower part of the valley of the Isère, are found the rocks intervening between the chalk and the new red or saliferous sandstone. Still more to the west, extending to the banks of the Rhône below the junction of the Bourbre, are found the supercretaceous strata.

The high road from Paris by Lyon, Chambéry, and Mont Cenis to Turin, passes through this department, also the road from Paris by Lyon to Aix, Marseilles, Toulon, Nice, and Genoa. The former enters the department just after it leaves Lyon, and passes by Bourgoin and La Tour du Pin to Pont de Beauvoisin, where it crosses the Guiers into Savoy. The road to Aix also enters the department just after leaving Lyon, and runs south by Vienne, along the valley of the Rhône, into the department of Drôme. The road from Paris to Grénoble branches from that to Chambéry and Turin at Bourgoins, and passes by Moirans and Voreppe, and along the valley of Grésivaudan to Grenoble: from this city two roads lead, one by the valley of the Isère into the Turin road at Montmeillan, the other by the valley of the Romanche to Briançon (Hautes Alpes) and by Mont Genèvre to Turin, with a branch by the valley of the Drac to Gap in the department of Hautes Alpes. The aggregate length of the *Routes Royales* is 336 miles, about two-thirds

of which are in good repair; the rest is out of repair or unfinished. The aggregate length of the *Routes Départementales* is 284 miles, more than seven-eighths of which are in good repair. The bye-roads and paths have an aggregate length of nearly 1400 miles.

The inland navigation is made up of that of the Rhône, 97 miles; and that of the Isère, 60 miles; together 157 miles.

The climate differs much according to the nature of the surface. In the plains the summer is very hot and the winds violent; in the marshy flats the temperature is lower and the air moister; in the deep valleys there are sometimes rapid changes of temperature, and at other times long periods both of rain and drought. The high mountains have but two seasons, a long winter of nine months, with a brief summer. The air of the department is generally keen, pure, and healthy; but the changes render the crops very uncertain. From the different elevation of the surface the natural productions are of very various character. The valley of Bourg d'Oysans, the most elevated of the larger valleys, produces rye, barley, potatoes, and a considerable quantity of hay: the valley of St. Laurent du Pont, or of the Chartreuse [CHARTREUSE], is in general covered with pine forests; some spots produce grain and hemp: the valleys of Voiron and Vizille are chiefly productive of hemp: the valley of Grésivaudan, one of the most fertile districts in France, produces grain of all sorts, wine, fruit, &c. The more level districts of the department have generally a dry, sandy, or stony soil; some parts however are marshy. The advancement of agriculture has increased the productiveness of these districts; some of the marshes have been drained, and the drier soils are improved by irrigation. The crops consist of wheat, rye, pulse, hemp, wine, fruit, and hay: and notwithstanding the injury done by a changeable climate, violent winds, and storms of hail, the produce of the department exceeds its consumption The wines, especially those of the neighbourhood of Vienne, are in good repute. The forests yield beech, elm, and especially pine timber. Many horses are bred; the mules are excellent; the asses small. The cattle are small, but the cows give much milk; and the cheese called Sassenage cheese, from a village or small town of that name near Grenoble, where it is chiefly sold, is excellent. Sheep are numerous, and have a fine soft fleece: immense flocks are driven every spring from the neighbouring departments to the upland pastures of the Alpine valleys. Goats, pigs, and poultry are numerous; and a considerable number of silkworms are reared in those parts which admit of the growth of the mulberry. Of wild animals there is considerable variety: the bear, the lynx, the chamois, the wild goat, and the marten, are found in the mountains: game is tolerably plentiful, and fish abundant.

The mineral wealth of the department is considerable. Gold, silver, lead, copper, iron in abundance, zinc, mercury, antimony, bismuth, cobalt, coal, rock-crystal, granite, marble, alum, sulphur, gypsum, marl, potter's clay, and sandstone are found; but of these, only lead, iron, and coal, with some marble quarries and clay pits, are wrought. The gold and silver mines have been abandoned, not being sufficiently productive to pay more than the cost of working them. There are several mineral springs.

The department is divided into four arrondissements as below: it contains forty-five cantons, or districts under a justice of the peace, and 555 communes:—

Name of Arrondissement and Situation.	Area in sq. miles.	Pop. 1836.	Communes.
Grenoble, S. & E.	1599	213,568	214
La Tour du Pin, N.	512	129,809	125
St. Marcellin, S.W.	413	85,267	84
Vienne, W.	681	145,001	132
	3205	573,645	555

In the arrondissement of Grenoble are the capital (population in 1836, 28,969) [GRENOBLE], Voreppe (population 1505), Sassenage, Goncelin, Theys, Allevard, and Fort Barraux, all on or near the Isère; Corps, Mens, La Mure (pop. 2785), Monetier de Clermont, Vif, Varces, and Claix, in or near the valley of the Drac; Le Bourg d'Oysans (pop. 3052) [BOURG], and Vizille (pop. 2422 town, or 2750 commune), in that of the Romanche; Le Villard de Lans on the Bourne; Les Echelles (pop. about 1500) and St. Laurent du Pont (pop. 3156) on the Guiers; the establishment, formerly monastic, of the Grand Chartreuse [CHARTREUSE, GRAND], in the desert near St. Laurent; Chirens, and Voiron (pop. 6924). At Vizelle are manufactures of printed cottons, yarn, and paper. Sassenage is the great mart for the cheese of the surrounding districts. It is also remarked for a natural curiosity,—two cylindrical excavations in two grottoes, in which the supply of water was once supposed to presage the abundance or failure of the harvest. Voiron is the mart for the linens manufactured in the department.

In the arrondissement of La Tour du Pin are the capital (pop. in 1836, 2484), Bourgoin (pop. 3447 town, 3762 commune), Virieu and Le Grand Temps near the Bourbe; St. Clef or St. Chef (pop. 3397) between that river and the Bourbre; St. Geoire (pop. 4635) and Le Pont de Beauvoisin (pop. 1943 town, 2139 commune) in or near the valley of the Guiers; Moretel, Quirieu, and Crémieu or Crémieux (pop. 2058 town, 2401 commune), in or near the valley of the Rhône. There are mineral springs at Le Pont de Beauvoisin.

In the arrondissement of St. Marcellin are St. Marcellin (pop. in 1836, 2885), St. André, Beauvoir, Vinay, Lalbene, Tulliens or Tullins (pop. 1806 town, 3807 commune), Moirans and St. Quentin, on or near the Isère; St. Antoine on the Furand; Roybon on the Galaure; Viriville and St. Etienne de Geoirs. St. Marcellin is in a pleasant situation amid vine-covered hills; it is well built, and surrounded with walls. The inhabitants trade in raw silk, chesnut and walnut oil, and wine.

In the arrondissement of Vienne, are the capital (pop. in 1836, 16,484) [VIENNE], Roussillon, Le Péage, and St. Symphorien, on or near the Rhône; Beaurepaire (pop. 1924 town, 2138 commune) on the Suzon; La Côte St. André (pop. 2800 town, 4568 commune), Chatonnay, St. Jean de Bournay (pop. 1820 town, 3392 commune), St. Georges (pop. 1636 town, 2872 commune), Heyrieux, and La Verpilière. The inhabitants of La Côte St. André carry on a considerable trade in liqueurs and in the light and sparkling white wines grown round the town.

The department contains many smelting-houses for iron, and some for lead; and a flatting-mill for copper. Iron guns for shipping, nails, and steel are manufactured: there are several potteries and a glass-house for making bottles. Sail-cloth, canvass for wrappers, coarse and fine linens, cotton yarn, calico and printed cottons, thrown silk, woollen cloth for the troops and for other uses, hats, leather of different qualities, and gloves (especially at Grenoble), paper and vellum (especially at Vienne), liqueurs, mineral acids, and turpentine are made. These various articles, with wine, brandy, wool, silk, hemp, and deals, constitute the exports.

The department constitutes the diocese of Grenoble; and is in the jurisdiction of the Cour Royal and the Académie Universitaire of that city. There is a Protestant consistory, of which Mens is the seat. The department is included in the seventh military division, of which the head-quarters are at Grenoble. It returns seven members to the Chamber of Deputies.

In respect of education the department is below the average of France. The proportion of young men enrolled in the military census of 1828-9 who could read and write was 29 in every 100.

This department formed in antient times part of the territories of the Allobroges, a nation of the Celtic stock; the southern parts were probably comprehended in the territories of two other people of Celtic race, the Segalauni and the Vocontii. In the Roman division of Gaul it was included in the province of Viennensis, a subdivision of the more antient and extensive province of Narbonensis. It contained the Roman cities of Vienna (Vienne) and Cularo, afterwards Gratianopolis (Grenoble). From the Romans it passed successively to the Burgundians and the Franks; and in the middle ages was included in Dauphiné. [BURGUNDIANS; DAUPHINÉ; FRANCE.]

ISIDORE, SAINT, of Pelusium in Egypt, lived in the beginning of the fifth century, and wrote, according to Suidas (*Isidorus*), '3000 epistles, explaining the divine Scriptures.' Upwards of 2000 are still extant; they are for the most part very short, and contain many repetitions. They have been published in Greek and Latin by Scholt, Paris, 1638. Dr. Heumann has published a 'Dissertation on Isidore' (Hanover, 1738, 4to.), in which he argues that most of the letters are fictitious, and not a real correspondence

ISIDORE, SAINT, bishop of Seville, in Spain, from A.D 595 or 596 to A.D. 636, one of the most celebrated of the Spanish bishops, was born at Carthagena. He was well acquainted with Greek and Hebrew, and was considered by the Council of Toledo (A.D. 650) as the most learned man of his age. The style of his works is however not very clear, and his judgment appears to have been very defective.

The most important of his works are: 'A Chronicle from the Beginning of the World to A.D. 626;' 'A Book of Ecclesiastical Writers,' in 33 chapters; 'Three Books of Opinions, selected from the writings of the fathers, and especially from St. Gregory;' 'Commentaries upon the historical books of the Old Testament;' 'Allegories on the Old and New Testaments;' 'Two Books of Ecclesiastical Duties,' printed in the 'De divinis Catholicæ Ecclesiæ Officiis ac Ministeriis,' Cologne, 1568; 'A Book of Prolegomena to the Old and New Testaments;' 'Twenty Books of Origines or Etymologies,' which were left unfinished and were published after his death by Braulio, bishop of Saragoza; the first edition of this work was published at Augsburg, 1472.

The works of Isidore have been published by Du Breul, Paris, 1601, and Cologne, 1617; at Madrid, 1778; and by Arevali, Rome, 1797, 1803.

ISIDORE of Charax*, lived probably in the first century of our æra. It appears from Athenæus (*Deip.* iii.) that he wrote an account of the Parthian empire, of which there is only a small part extant, entitled Σταθμοὶ Παρθικοί, or the 'Parthian Halting-places.' This work gives a list of the eighteen provinces into which the Parthian empire was divided, with the principal places in each province, and the distances between each town. This list was probably taken from official records, such as appear, from the list of provinces, &c. in Herodotus, to have been kept in the antient Persian empire.

This work has been printed in the second volume of Hudson's 'Geographiæ veteris Scriptores Græci Minores,' with a Dissertation by Dodwell. There is also a Mémoire on Isidore by Sainte-Croix in the 50th volume of the 'Académie des Belles-lettres;' and some remarks on the 'Parthian Halting-places' in the 'Journal of Education,' vol. ii., p. 305, where the question of the site of Ecbatana is discussed and determined.

ISINGLASS is animal jelly, or gelatin, nearly pure. The best isinglass is prepared in Russia from the membranes of the sturgeon, especially from its air-bladder and sounds, which are remarkably large. These, when removed from the fish, are washed with cold water, and exposed a little to the air, in order that they may stiffen; the outer skin is then taken off and rejected, and the remainder cut out, and loosely twisted into rolls, according to the intended size of the pieces, which are called *staples*, and are known in commerce by the names of long and short staple, and of these the first is the best: these are dried in the air. The best sort of isinglass is used for the table and in confectionary; it is also largely employed in refining wine and beer.

Isinglass is nearly colourless, has but little taste or smell, is translucent in thin pieces, and is soluble in water; one part of it dissolved in 100 parts of hot water give a solution which completely stiffens in cooling.

Isinglass is also dissolved by most acids readily, and also in solution of potash and soda, but not in alcohol. Several metallic salts and oxides have the property of precipitating a solution of isinglass, but corrosive sublimate does not produce this effect, which serves to distinguish it from albumen; but it resembles this substance in being precipitated by infusion of galls or of oak-bark. Isinglass is extremely nutritious.

According to Gay-Lussac and Thenard it consists nearly of—

Seven equivalents of	hydrogen	7
Seven "	carbon	42
Three "	oxygen	24
One equivalent of	azote	14
Equivalent		87

ISIS, one of the chief deities of the Egyptians, the sister of Osiris, was represented as the Goddess of Fecundity, and the cow was therefore sacred to her. She was said to have first taught men the art of cultivating corn. The annual festival of Isis in Egypt lasted eight days, during which a general purification took place. The priests of Isis were bound to observe perpetual chastity, their heads were shaved, and they went barefooted. The goddess was often represented as a woman with the horns of a cow. She also appears with the lotus on her head and the sistrum in her hand; and her head in some instances is seen covered with a hood. Heads of Isis are a frequent ornament of Egyptian capitals on the pillars of the temples. [DENDERAH; EGYPTIAN ARCHITECTURE.]

As the worship of Isis passed into foreign lands, it assumed a foreign character, and many foreign attributes, as we see from the Greek and Roman writers. Sometimes she is represented like Diana of Ephesus, the universal mother, with a number of breasts. The mysterious rites of Isis were probably in their origin symbolical: on one of her statues was the inscription, 'I am all that has been, that shall be; no mortal has hitherto taken off my veil.' But the Isiac rites, transplanted to Italy, became a cloak for licentiousness; and they were repeatedly forbidden at Rome. Tiberius had the images of Isis thrown into the Tiber, but the worship revived, and Juvenal speaks of it in an indignant strain. The Isiac table in the Turin Museum, which is supposed to represent the mysteries of Isis, has been judged by Champollion to be the work of an uninitiated artist, little acquainted with the true worship of the goddess, and probably of the age of Hadrian. (Plutarch's *Treatise on Isis and Osiris*, Wyttenbach's ed., ii. 441; Herod., ii. 41, 42, 123, &c.; Pausan., ii. 13, 7, and particularly x. 32, 13.)

ISLA, or **ISLAY**, the most southern of the Hebrides, belongs to the shire of Argyle, and is 28 miles long and about 18 in breadth. This island, which was once the kingdom of the Norwegian Lords of the Isles, retains but few vestiges of the manners of its early inhabitants. Though generally of a mountainous character, especially towards the north, there is much low and cultivated land. Many of the farmers are comparatively opulent, and practise the lowland system of agriculture. The houses are good, and the roads are kept in good repair. There are several lakes, and the island is well watered by numerous streams and rivulets, which abound with trout and salmon. Isla appears also to be rich in minerals. A copper-mine has been worked here for many years, but the ore is much mixed with lead, which renders the separation expensive and troublesome. The district of Islay comprises six parishes, besides the island of Collonsay, the united population of which in 1831 was 19,780.

(M'Culloch's *Highlands and Western Isles of Scotland*; *Population Returns*, &c.)

ISLAM. [MOHAMMED.]

ISLE of BOURBON. [BOURBON.]

ISMAELITES, or **ISMAELIANS**, were originally a branch of the Shiites, or followers of ALI BEN ALI TALEB. Djafar Madeck, the sixth Imaum in a direct line from Ali having lost his elder son Ismael, appointed his younger son Mousa to be his successor. This caused a schism among the Shiites in the second century of the Hegira. Those who contended that the office of Imaum ought to have descended to the posterity of Ismael, and not to his younger brother, were called Ismaelites, and also Karmathi and Batenis; in Persia they were called Talimis, from the word Talimi, which means 'learning,' because they maintained, contrary to the orthodox Mussulmans, that man can learn the truth only by studying. They established two powerful dynasties, one in Egypt [FATIMIDES], and another in the Irak Ajemi, a part of Persia, the capital of which was Casbin. The Assassins of Persia and Syria were a fanatical sect of Ismaelites. [ASSASSINS.] The Ismaelites of Persia, Syria, and Arabia had frequent wars against the Abbaside caliphs and the other Sunnee Mussulmans, until the dynasty of Casbin was overthrown by the Tartars about the middle of the thirteenth century. After that time the Ismaelites became scattered through Asia, maintaining their tenets and observing their rites in concealment and obscurity. Their tenets appear to have been of a loose kind; they were the freethinkers of Mohammedanism. At the end of the last century they were still existing in Persia, and had their Imaum at Khakh, a village in the district of Khom, enjoying the protection of the Shah, although considered as heretics by the Persian Shiites. They had followers even in India. (J. F. Rousseau, *Mémoire sur les Ismaelis et les Nosaïris*, with notes by De Sacy.) Those of Syria have continued to live in the mountains of

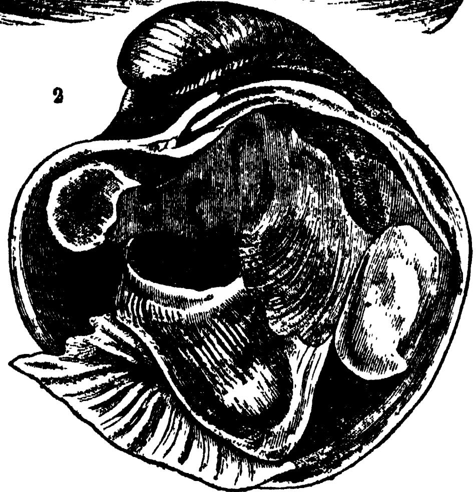
* There were several towns of this name; one in Media, another in Parthia, and a third at the mouth of the Tigris. It is doubtful at which of them Isidore was born.

Semmak, which join Lebanon, and their chief place was Maszyad, near Hamah on the Orontes. The Druses are supposed by some to be a ramification of the old Ismaelites, but they are a distinct people, both in their religious and social character, from the present Ismaelians. [DRUSES.] In 1809 the Nosaïris, another sect living in the same mountainous tract, took Maszyad by surprise, murdered the Emir, with most of the Ismaelian inhabitants, and carried off a large booty. The Ismaelians of Syria have never recovered from that blow, but have remained poor in importance and numbers, and are under the nominal dominion of the Turks. Their tenets are not well known, but they seem to have deviated from the original doctrines of the great Ismaelite sect, and to have mixed them up with gross superstitions. They can hardly be called Mussulmans; they have no mosques, but are circumcised, and they still visit the tomb of Ali at Meshed. They are said to be simple and hospitable, and have a better reputation than their neighbours the Nosaïris.

ISMAIL. [BESSARABIA.]

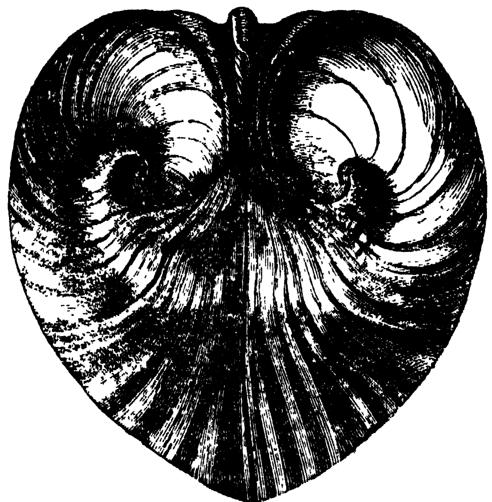
ISMID, or ISNIKMID. [ANATOLIA; BITHYNIA.]

ISOCA'RDIA, a genus of conchifers. Linnæus placed the form under *Chama;* Bruguière arranged it among the *Carditæ;* Lamarck, who made it the last of the genera of his *Cardiacées*, separated it from the last-mentioned genus, giving it the generic name at the head of this article. Mr. G. B. Sowerby (*Genera of Recent and Fossil Shells*) thinks that this separation was effected with good reason, because the involute divaricate *umbones* of *Isocardia*, and its consequently dichotomous ligament running in each valve to the point of the *umbo*, serve to distinguish it from the other *Carditæ* of Bruguière. M. de Blainville, under the name of *Isocardium*, inserts it between *Tridacna* and *Trigonia* among his *Camacés*. M. Rang retains it in the same family, but restores Lamarck's original termination of the name, and places it between *Caprina* and *Tridacna*.



M. Deshayes, in his edition of Lamarck, remarks that the *Isocardiæ* have, in truth, large and contorted *umbones* like *Chama* and *Diceras*, but that they are regular and always free, while the true *Chamæ* are adherent and irregular. From the *Carditæ*, he observes, they are to be distinguished, both as respects the shell and the animal. In *Cardita* the lobes of the mantle are separated throughout their length, and are without siphons. In *Isocardia* the lobes of the mantle are united posteriorly, and provided with two short siphons, or rather perforations, which may be compared with those of the *Cardia*. Here doubtless, says M. Deshayes, the *Isocardiæ* approach the *Cardiæ;* but when the foot and the form of the branchiæ in these two genera are compared, the distinction is obvious. In the *Cardia* [CONCHACEA, vol. vii., p. 426-7], the foot is cylindraceous, very long, and bent in an elbow-like form in the middle; in the *Isocardiæ*, on the contrary, it is flat, subquadrangular, and rather short.

Generic Character.—Animal more or less globular, having the borders of the *mantle* fringed with very fine tentacular papillæ, leaving a rather large opening between them at the lower part, and united posteriorly by a transverse delicate band, pierced with two orifices surrounded by papillæ, one for the vent, and the other, lower, for respiration: *foot* of moderate size and trenchant.



Shell sometimes with an epidermis, very convex, globulose, heart-shaped, equivalve, inequilateral; *umbones* divaricated, and widely divergent, curved forwards and outwards, and slightly spiral; *hinge* composed of two flattened hinge-teeth; *ligament* external, forked at one of its extremities; *muscular* impressions very distant.

The Rev. James Bulwer, from whose figure in the *Zoological Journal*, vol. ii., the two upper figures are taken, saw the animal when in sea-water, and in the position represented at No. 1. The feelers, or ciliated fringe of the upper orifice (the largest) of the mantle, moved slowly, as if in search of food. Having remained in this situation about ten minutes, water was ejected with considerable force from the lower orifice, which had till then remained motionless. The expulsion of the water appeared to be effected by a sudden contraction of the muscles, because this was never done without the valves nearly closing at the same instant. After a few seconds, the valves gradually returned to their open position, and remained quiescent as before, till the water was again ejected with a jerk; this alternating process was repeated during the whole time his specimens (which were trawled up in very deep water on the east coast of Ireland) were under his examination, but at shorter intervals on receiving fresh supplies of sea-water. The animal appeared to Mr. Bulwer to be insensible both to sound and light, as the presence or absence of either did not at all interrupt its movements; but its sense of feeling appeared to be very delicate. Minute substances dropped into the orifice of the mantle instantly excited the animal, and a column of water strongly directed expelled them from the shell; with so much strength was the water in some instances ejected, that it rose above the surface of three inches of superincumbent fluid. (*Zool. Journ.*, vol. ii., p. 359.)

Isocardia Cor. 1, valves open, to show the animal and the feelers or ciliated fringe of the upper and lower orifices; 2, one of the valves, showing the animal with its sharp-edged foot and the muscular impressions.

Shell of Isocardia Cor, valves closed.

Lamarck recorded four species, including *Isocardia semisulcata*, which we shall presently have to notice: M. Deshayes, in his edition of that author, adds four others, reckoning that species; making eight in all, recent and fossil.

Geographical Distribution of the Genus.—The European and East Indian Seas, and those of New Holland.

Isocardiæ have been dredged up from mud and sand at depths ranging from 10 to 20 fathoms.

FOSSIL ISOCARDIÆ.

Mr. G. B. Sowerby remarks (*Genera of Recent and Fossil Shells*) that several fossil species are given in plate 295 of Sowerby's 'Mineral Conchology,' one of which is from the London clay, and the other from Kelloway's. Mr. G. B. Sowerby, in a note, states that a fossil species also occurs in the *crag*, which so nearly resembles the *I. Cor* that he knows not wherein the specific difference consists; and, in

the text, goes on to state that according to Brocchi (*Conch. Foss. Subap.*, ii. 520), two varieties of *I. Cor* are found in a fossil state in several parts of Italy; but as a subject upon which much diversity of opinion exists is here brought into question, he would recommend an attentive and comparative re-examination of the fossil with recent specimens, before the inquirer comes to an absolute decision upon this point. Another fossil species, he observes, is found at Piacenza, viz. *I. arietina*, Lam.; and he has figured *I. Basochiana* (Defr., *Dict. des Sciences Naturelles*), a new species found by M. de Basoches de Falaise, in the district of Coutances. He thus concludes his remarks upon the fossil species of this genus: 'We think we may venture to express our opinion that all the fossil specimens published in various books, and existing in various collections, are not distinctly characterized *Isocardiæ*, but only the casts of the insides of other bivalves: the best distinguishing character is in the groove formed for the extension of the ligament from the hinge to the umbo. It is incumbent on us to mention that in *Isocardia* the line to which the mantle is attached, passing from one muscular impression to the other, is entire.'

M. Deshayes, in his tables, records two living species and three fossil (tertiary); and *Isocardia Cor* as both living and fossil (tertiary).

Of *Isocardia semisulcata* M. Deshayes (ed. of Lamarck) states that it is to be presumed that the species had been added after the calamity which had befallen the professor: this distressing privation compelled Lamarck to have recourse to the eyes of others; and M. Deshayes is of opinion that this species owes its presence among the *Isocardiæ* to its external form, which has in fact an approximation to the shells of that genus. But, continues the same author, if the hinge and other essential characters had been examined, it would have been perceived that this shell had nothing about it which constitutes the character of an *Isocardia*. He thinks that the form approaches *Mya* and *Anatina*, and that it ought to constitute a particular genus. M. Deshayes then relates that he had some time ago remarked in the collection of M. Michelin a small fossil shell from the environs of Senlis, which afforded such characters as induced M. Deshayes to comprehend it in the group of *Anatinæ* as a genus. He states that this genus had already been established by Shumacher under the name of *Periploma;* but he thinks it right to adopt the name of De Haan, so well known for his treatise on Ammonites and other important works, who had shown to him a recent shell from New Holland presenting exactly the same characters with those of M. Michelin's fossil. M. Deshayes then saw that the two species could not make part of the genus *Periploma*, and that they ought to constitute a new genus. The shell which M. De Haan communicated to him was, he says, the same as that named *Isocardia semisulcata* by Lamarck. M. Deshayes describes it under the name of *Cardilia;* and he records two species—one living, *Cardilia semisulcata*, Deshayes (*Isocardia semisulcata*, Lam.), the other *Cardilia Michelini*, Deshayes, for which he gives as a synonym *Hemicylconosta Michelini*, Deshayes.

Mr. Lea places his genus *Hippagus* (of which he gives an engraving) under the family *Cardiacea*. (*Contributions to Geology*, 8vo., Philadelphia, 1833.) He states that he has in vain endeavoured to place this shell in one of the established genera. In its general character he says that it approaches most closely to the *Isocardia Cor*, but that it cannot be placed in that genus, being destitute of teeth. It bears, he adds, some resemblance to the genus *Inoceramus;* but, he continues, the hinge in that genus 'closes by a series of oblong fossets,' and besides it is very inequivalve. In its natural order he thinks that it seems to follow the genus *Isocardia*, and he proposes to place it in that position. *Hippagus* occurs in the Claiborne beds (tertiary of Alabama—Eocene of Lyell).

ISOCHRONOUS, ISOCHRONISM (ἴσος, equal, χρόνος, time). Vibrations or oscillations which are performed in equal times are called isochronous; and isochronism is the name given to a remarkable property of all systems which are in equilibrium, namely, that when slight disturbance, be the same more or less, is given, the oscillations which take place are all performed in the same time, or so nearly in the same time, that any acceleration or retardation is totally imperceptible. Thus, when a pendulum is allowed to vibrate till it rests, it will be found that there is no perceptible difference between the vibrations of longer and shorter extent; of which any reader may satisfy himself by attaching a weight to a string, and observing the vibrations. But a still better proof may be found in a musical string. the finest ear cannot detect any difference between the pitch of a note made by a smart blow on the key of a pianoforte and that made by a gentle one; yet a very small difference in the number of oscillations per second would be perceptible, and the amount of disturbance from the position of equilibrium is twenty or thirty times greater in the first case than in the second.

When, under two different circumstances, the longer space is described in the same time as the shorter, it must be that the force acting in the first case is greater than that in the second; and it is sufficiently known from experience, that the more a system at rest is disturbed, the greater is the effort which it makes to return. But in order that there may be isochronism, it is not sufficient that the effect to return should increase with the amount of disturbance, but the increase must take place according to one particular law. This law is as follows:—the force of restitution must be always proportional to the disturbance, so that whatever force begins to act when the disturbance is *a*, twice as much acts when the disturbance is twice *a*; and so on for all proportions. That this law does prevail when the disturbance is not great, either absolutely, or so nearly that its error is extremely small, may be proved both by theory and experiment. The most complete proof is to be found in the 'Mécanique Analytique' of Lagrange. Granting the law, we can make it sufficiently apparent that the consequence must follow, namely, that all vibrations are performed in equal times. Let A and B be two material

points which are urged towards the point O by pressures which are proportional to OA and OB; and further let each pressure diminish as either point approaches towards O, so as always to preserve between the pressures at any two points the proportions of the distances of those points from O. Take a minute portion of time, so small that the pressure may not vary sensibly during its continuance: then [ACCELERATION; FALL OF BODIES] the velocities created and the spaces described in that time will be proportional to the pressures producing them. If then, during that time, A move to K and B to Q, AK and BQ (and therefore OK and OQ) will be in the proportion of OA to OB, and the points will be at K and Q, with pressures and velocities proportional to OK and OQ. In a second such instant let the points move to L and R: then KL and QR, partly due to velocities which are as OK to OQ, and partly to accelerations which are in the same proportion, will still be in the proportion of OK to OQ, or of OA to OB. Consequently the whole AL is to the whole BR in that proportion: and reasoning in this way for successive small accelerations, we show that the whole space moved over by A in any time is to that moved over by B in the same time in the proportion of OA to OB. Consequently A describes AO in the same time in which B describes BO; or the half of a vibration of A is made in the same time as half a vibration of B.

To make this process perfectly strict, recourse must be had to the considerations in INTEGRAL CALCULUS.

ISO'CRATES, one of the Greek orators commonly called the Ten, was born at Athens, 436 B.C. He studied rhetoric under Prodicus, Gorgias, Tisias, and Theramenes, and became a master of his art. A certain timidity and feebleness in his delivery prevented him from speaking in public (*Panathenicus*, c. 4), and he was therefore debarred from occupying the high stations which were open to the ambition of his contemporaries. He taught rhetoric both at Chios and at Athens, and his school was attended by numerous disciples, among whom were Xenophon, Ephorus, Theopompus, and other distinguished men of his time. Although no orator himself, he formed many orators; and Isæus, Demosthenes, and others, are said to have studied under him. He is said to have charged one thousand drachmæ for a complete course of oratorical instruction, and to have said to some one who observed on the largeness of the amount, that he would willingly give ten thousand drachmæ to any one who should impart to him the self-confidence and the command of voice requisite in a public orator. The orations of Isocrates were either sent to the persons to whom they were addressed for their private perusal, or they were en-

trusted to others to deliver in public. He is said to have delivered only one himself. Isocrates treated of great moral and political questions: his views are distinguished by a regard for virtue, and an aversion to all meanness and injustice. His politics were conciliatory; he was a friend of peace; he repeatedly exhorted the Greeks to concord among themselves, and to turn their arms against their common enemy Persia. In his 'Panegyrical Oration' (published about B.C. 379), which he wrote in the time of the Lacedæmonian ascendency, he exhorted the Lacedæmonians and Athenians to vie with each other in a noble emulation, and to unite their forces in an expedition against Asia; and he descanted eloquently on the merits and glories of the Athenian Commonwealth, on the services it had rendered to Greece, and on its high intellectual cultivation; while he defended it from the charges, urged by its enemies, of tyranny by sea, and of oppression towards its colonies. He addressed Philip of Macedon in a similar strain after his peace with Athens (B.C. 346), exhorting him to reconcile the states of Greece, and to unite their forces against Persia. He kept up a correspondence with Philip, and two of his epistles to that prince are still extant, as well as one which he wrote to the then youthful Alexander, congratulating him on his proficiency in his studies. But although Isocrates was of a mild and conciliatory disposition, he displayed considerable courage on several occasions, as when he showed his sympathy for Theramenes, who had been condemned by the thirty tyrants; and lastly, he proved that though no violent partisan, he was a warm-hearted patriot, when, at the news of the battle of Chæronea, he refused to take food for several days, and thus closed his long and honourable career at ninety-eight years of age, B.C. 338.

There are extant eight orations of Isocrates of the class called judicial, or forensic (λόγοι δικανικοί), which are valuable for the subject matter. In his oration in favor of the Platæans he took the part of that people, who were expelled from their homes by the Thebans. The oration against Euthynous, which appears to be incomplete, and may possibly never have been spoken, is a most ingenious attempt to determine a dispute as to the restoration of a deposit of money where there was an absence of all direct testimony as to the main fact. The orator puts the probabilities on each side in two opposite scales, and weighs them with consummate skill. Three of the orations of Isocrates—to Demonicus, to Nicocles, and the oration entitled Nicocles, belong to the Parænetic or hortatory class, and the first two partake in some degree of the epistolary style. Isocrates' 'Panathenaicus' is a panegyric of Athens, which he wrote when he was 94 years of age. (*Panath.* c. 1.)

The style of Isocrates is singularly perspicuous, but highly laboured, and somewhat diffuse. In Cicero's opinion it was he who first gave to prose writing its due rhythm. The art of Isocrates is always apparent, a circumstance which of itself diminishes in some degree the effect of his writings, and is almost inconsistent with vigor and force. The oration to Demonicus is an almost uninterrupted series of antitheses. Isocrates, though he falls far below the great orator of Athens, is still a perfect master in the style which he has adopted, and has well merited the high encomium of Dionysius for the noble spirit and the rectitude of purpose which pervade his writings. This judicious critic has thus briefly summed up his comparison between Lysias and Isocrates. 'As to the charm of composition, Lysias is superior to Isocrates in the same kind that a naturally handsome person is to one made so by art: the composition of Lysias pleases naturally; that of Isocrates aims at pleasing.' Plutarch says that sixty orations went under the name of Isocrates, of which only twenty-five or twenty-eight at most were his; twenty-one of these have come down to us, together with a few epistles, probably not genuine. 'Isocratis Opera,' Greek and Latin, were edited by the Abbé Auger, 3 vols. 4to., Paris, 1782, with several biographies of Isocrates: this edition is of small value. The best edition of the Greek text is by Bekker; the edition of Koray, Paris, 1807, 2 vols. 8vo., is useful. Isocrates was translated into English by Richard Sadleir, London, folio (no date); by Dinsdale, London, 1752, 8vo.; and by Gillies, together with the Orations of Lysias, London, 1778, 4to. (Dionysius of Halicarnassus; *Life of Isocrates*, attributed to Plutarch; Cicero, *De Claris Oratoribus*, c. 8; Quintilian, *Instit.* iii. x. &c.; Photius, *C.* 260.)

I'SODON. [CAPROMYS; MURIDÆ.]

ISOMERISM, a term suggested by Berzelius (from ἴσος, *equal*, and μέρος, *part*) to designate certain compounds which contain the same elements in the same ratio, and yet possess physical and chemical properties quite distinct. Berzelius has indeed employed three terms to include the different cases of bodies having the same composition and different properties; they are classed as *isomeric, polymeric,* and *metameric* substances.

Isomeric bodies are those which contain the same absolute and relative number of atoms of the same elements, and have consequently the same atomic weight. In this class are included the two states of peroxide of tin, of phosphuretted hydrogen, &c. &c. Professor Graham has however shown that the difference in the two oxides of tin is owing to one of them being a hydrate; and that the difference between the two phosphuretted hydrogens is derived from the presence of a very minute portion of an adventitious compound, which renders one of them spontaneously inflammable. The cyanic and fulminic acids are also classed as isomeric bodies, and it is admitted that cyanic acid is an oxide of cyanogen, but it is remarked by Professor Graham that we have no proof of the existence of cyanogen in fulminic acid, for though its elements are present in such proportions as to form it, they may be differently combined.

Should any real isomeric bodies be found, it is evident either that they must contain more than two elements, or two equivalents of one, if there be only two; thus supposing the two oxides of tin to have been really isomeric, they might be regarded as having their elements arranged so as to form a binoxide, SnO^2, or as a protoxide combined with oxygen, $SnO+O$; it is however exceedingly doubtful whether any such compounds exist.

Polymeric substances are those which contain the same relative but not the same absolute number of atoms of the same elements, and whose atomic weights are consequently unlike. Several carburets of hydrogen [HYDROGEN, *Carburetted*] offer examples of polymerism. Hatchetine, olefiant gas, and etherin are respectively solid, gaseous, and fluid, and they differ as much in their chemical relations as in their obvious properties; yet they all consist of six parts by weight of carbon, and one part by weight of hydrogen, which are the equivalent weights of these elements, or represent one atom of each.

It has been already mentioned that of two isomeric bodies which contain only two elements, one at least must be in double proportion, for no cause would otherwise appear to exist for their different forms and properties. If however, in the case of the hydrocarbons above cited, and such as are analogous, we suppose hatchetine to consist of one equivalent of each of its elements, olefiant gas of two, and etherin of four, their similarity of proportions is maintained though their quantities differ, and their elements may be so differently arranged as to cause the difference of properties which they are actually found to possess. Thus the one equivalent of hydrogen and carbon in hatchetine may be arranged $H+C$; the double quantities in olefiant gas $HHC+C$; quadruple proportions in etherine $HHHC+HCCC$. The first is a binary compound of elements; the second is constituted of a compound and an element; and the third of two compounds. Unless there were reasons for supposing etherin to consist of four equivalents of each of its elements, it might be imagined to result from a different arrangement of double elements, as $HCC+H$. With respect to olefiant gas, it actually happens that its combining weight is exactly double that of a simple carburet of hydrogen; for 36, or 1 equivalent of chlorine, unite with $14 = H^2C^2$, presumed to represent one equivalent of olefiant gas. [HYDROGEN, *Chloride of Hydrocarbon.*]

Metameric substances are those which, while they contain the same absolute and the same relative number of atoms of the same elements, yet constitute substances belonging to an entirely *different class* of bodies, or a *different order* of chemical compounds. For a list of metameric bodies, and further information on the subject, we refer to Professor Johnstone's statement (*Reports of the British Association*, vol. i.), from which we quote the following illustrative case:—cyanuric acid when heated, and without giving off or absorbing any thing, is wholly converted into hydrous cyanic acid; that is, it is changed from a compound atom of the first order, or from an oxide of a ternary radical, $\frac{1}{3}$ (Cy+2O+H), into a compound atom of the second order; into an acid chemically combined with water ($\dot{C}y+\dot{H}$). These two substances Berzelius calls metameric modifications of each other.

ISOMETRICAL PERSPECTIVE. [PERSPECTIVE.]

ISOMORPHISM (from ἴσος, *equal*, and μορφή, *form*). In the year 1819 it was found by Mitscherlich that certain substances which have the property of assuming the same crystalline form may be substituted for each other in combination without altering the form of the crystal. Thus crystals which have the aspect and form of alum, a salt which is well known to contain sulphate of potash and sulphate of alumina, may be made with sulphate of potash and persulphate of iron, hence it is concluded that alumina and peroxide of iron are isomorphous; and it is also found that the primary form of alumine or corundum is a rhomboid, which differs only a few degrees from that which is the primary form of peroxide of iron or specular iron ore.

The law of isomorphism, as announced by Mitscherlich in its utmost generality, is as follows: 'The same number of atoms combined in the same way produce the same crystalline form, and the same crystalline form is independent of the chemical nature of the atoms, and is determined only by their number and relative position.' This view has however been since abandoned by its author, and, as stated by Dr. Turner, his opinion now appears to be 'that certain elements which are themselves isomorphous, when combined in the same manner with the same substance communicate the same form;' and he proceeds to state, in illustration of this doctrine, that similarly constituted salts of arsenic acid and phosphoric acid yield crystals of the same figure, because the acids, it is thought, are themselves isomorphous; and as the atomic constitution of these acids is similar, each containing the same number of atoms of the other ingredient, it is inferred that phosphorus is isomorphous with arsenic.'

Several distinct groups of isomorphous bodies have been described by Mitscherlich; from these we shall select the salts of phosphoric and arsenic acids as examples: the neutral phosphate and the biphosphate of soda have exactly the same form as the arseniate and binarseniate of soda; phosphate and biphosphate of ammonia correspond with arseniate and binarseniate of ammonia; and the biphosphate and binarseniate of potash have the same form; each phosphate has a corresponding arseniate, possessing the same form, the same number of equivalents of acid, alkali, and water of crystallization, and differing only in the fact that one series contains phosphorus and the other an equivalent quantity of arsenic.

A list of isomorphous mineral groups is given by Professor Miller, of Cambridge, in the first volume, p. 118, of the 'Reports of the British Association;' and Professor Johnstone has published a list of isomorphous bodies arranged in their several groups, in p. 225 of the same volume, from which the annexed has been abbreviated by Dr. Turner.

1.

Silver	Ag.
Gold	Au.

2.

Arsenious Acid (in its unusual form)	As^2O^3.
Sesquioxide of Antimony	Sb^2O^3.

3.

Alumina	Al^2O^3.
Peroxide of Iron	Fe^2O^3.

4.

Salts of Phosphoric Acid	P^2O^5.
„ Arsenic Acid	As^2O^5.

5.

Salts of Sulphuric Acid	SO^3.
„ Selenic Acid	SeO^3.
„ Chromic Acid	CrO^3.
„ Manganesic Acid	MnO^3.

6.

Salts of Oxichloric Acid	Cl^2O^7.
„ Oximanganic Acid	Mn^2O^7.

7.

Salts of Potash	KO.
„ Ammonia with 1 eq. of water	H^4NO.

8.

Salts of Soda	NaO.
„ Oxide of Silver	AgO.

9

Salts of Baryta	BaO.
„ Strontia	SrO.
„ Lime (in Arragonite)	CaO.
„ Protoxide of Lead	PbO.

10.

Salts of Lime	CaO.
„ Magnesia	MgO.
„ Protoxide of Iron	FeO.
„ „ Manganese	MnO.
„ „ Nickel	NiO.
„ „ Zinc	ZnO.
„ „ Cobalt	CoO.
„ „ Copper	CuO
„ „ Lead (in plumbo-calcite)	PbO

11.

Salts of Alumina	Al^2O^3.
„ Peroxide of Iron	Fe^2O^3.
„ Oxide of Chromium	Cr^2O^3.
„ Sesquioxide of Manganese	Mn^2O^3.

The doctrine of isomorphism has been very generally received, yet the difficulties which attend it, and the liberties which some of its advocates have taken with what were previously regarded as the facts of chemical science, in order to support their theory, have prevented its universal adoption. Alluding to the supposed isomorphism of the arsenic and phosphoric acids, Mr. Brooke remarks, 'From other observations it appeared that barytes, strontian, and oxide of lead ought to be isomorphous; and hence that the salts of those substances, when produced by the same acid, ought also to be isomorphous.

But on examining the sulphates and acetates, it was discovered that their respective angular measurements were not alike, and they were ascertained therefore not to be strictly isomorphous. The sulphates are right rhombic prisms, and a corresponding dihedral angle of each afforded the following measurements:—

Sulphate of barytes	101° 42′
„ strontian	104°
„ lead	103° 42′

It became necessary therefore that the doctrine of isomorphism, in the strict sense of the term, should as a general principle be abandoned; and it is not unreasonable to conclude that the crystals which suggested the theory, and which appear to measure alike, may really differ in some small quantity which the goniometer does not detect.

But although the doctrine of isomorphism, or absolute *identity* of form, cannot be supported, it has been said that the forms in each respective case belong to the same *system of crystallization*, and they have therefore been termed *plesiomorphous* by Mr. (now Professor) Miller, of Cambridge, in a paper on some artificial crystals read to the Cambridge Philosophical Society, in March, 1830; and if ever the class of primary form can be indicated with certainty by the chemical composition of a crystallized body, a benefit will so far have been conferred on science by the the theory of M. Mitscherlich.' (*Phil. Mag. and Annals*, xi., 162.)

As connected with the subject of isomorphism, it will be proper to notice two other classes of bodies, which have been termed *dimorphous* and *isodimorphous* substances.

The case of dimorphism first ascertained was presented by carbonate of lime in the two incompatible crystalline forms of common calcareous spar and of arragonite. It was attempted to account for the difference by the fact that arragonite frequently contains a small portion of carbonate of strontia and of water; but it has since been found that these varying forms of carbonate of lime may be obtained artificially, and both in a pure state; thus when an alkaline carbonate is added to a cold solution of chloride of calcium, the carbonate of lime precipitated is analogous to calcareous spar; while that thrown down from a hot solution of the chloride is similar to arragonite.

It was also soon afterwards discovered that sulphur crystallized from fusion differs essentially in its form from the natural crystals and those deposited from bisulphuret of carbon. So also the diamond and graphite, which are both pure carbon, crystallize in forms which are incompatible with each other. A table of the dimorphous bodies at present known has been given by Professor Johnstone, in the *Seventh Report of the British Association.*

The term isodimorphous is proposed by Professor Johnstone to express the fact that two substances known to be dimorphous, the carbonates of lime and lead, crystallize each in two forms, the analogous pairs of which are also isomorphous.

In the paper above alluded to, Professor Johnstone has also given a table of isodimorphous groups.

ISOPERIMETRICAL. [VARIATION, CALCULUS OF.]

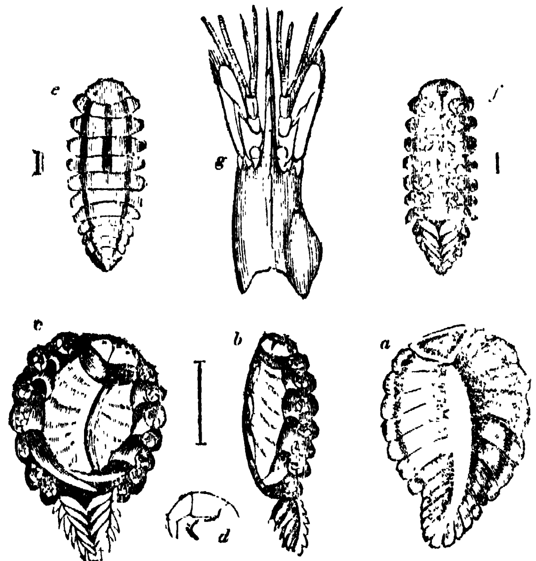
ISO'PODA, Latreille's name for the fifth order of crustaceans. These Isopods, according to that zoologist, approach the *Læmodipoda* by the absence of mandibular palpi (but see post, p. 56), though they are removed from them by several points; the two anterior feet are not annexed to the head, and, like the succeeding ones, depend upon their particular segment. The feet are always fourteen in number, unguiculated, and without any vesicular appendage at their base. The under part of the tail is furnished with appendages which are very apparent, and in the form of leaflets, or vesicular purses. Of these, the two first, or external ones, ordinarily cover the others, either totally or in great part. The body is generally flattened and wider than it is thick. The mouth is composed of the same pieces as in the crustaceans which precede it in M. Latreille's system, but in the order before us those which answer to the two superior jaw-feet in the *Decapods* present more the appearance of a lower lip terminated by two palpi. Two of the antennæ, the mesial ones, are almost obliterated in the last genera of this order, which are all terrestrial, and differ besides from the other by their respiratory organs. The male sexual organs are pointed out most frequently by the presence of linear or filiform appendages, and sometimes by hooks placed at the internal origin of the first subcaudal laminæ. The females carry their eggs under the breast, either between the scales or in a membranous pouch or sac that opens to afford a passage for their young, which are hatched with the form and parts proper to the species, and only cast their skin as they increase in size. The greater number live in the waters. Those which are terrestrial have need, like other crustaceans that live out of water, of a certain degree of atmospherical humidity, in order that respiration may be carried on, and that their branchiæ may be in a fit state for performing this function.

ORGANIZATION.

MM. Victor Audouin and Milne Edwards have given some most interesting particulars of the organization of the Isopods, the *Ligiæ* especially. (*Annales des Sciences Nat.*, August, 1827.) It appears from their observations that the *heart* has the form of a long vessel extended above the dorsal surface of the intestine. Its anterior extremity gives off three *arteries*, as in the *Decapods*. The lateral *branchiæ* may also be seen directed from the heart towards the feet. At the edge of the two first articulations of the abdomen, or tail, this organ receives, both right and left, small canals (the branchio-cardiac vessels) which seem to come from the branchiæ. According to the demonstrations of these zoologists in the case of the *Ligiæ*, it would appear that the *venous system* is less complete than in the *Macrurous Decapods;* and that the blood driven from the heart to the different parts of the body passes into *lacunæ*, which the organs leave between them at the lower surface of the body, and which have a free communication with the different vessels of the branchiæ. The *blood*, after having traversed the respiratory apparatus, returns to the heart in traversing the branchio-cardiacal vessels. This disposition would establish the passage from the circulating system of the *Decapod* crustaceans to that of the *Branchiopods*. According to Cuvier, the two anomalous chords composing the mesial part of the nervous system of the *Onisci* (and probably of the other *Isopods*, and even of the *Amphipods*) are not entirely approximated, and may be well distinguished throughout their length. There are nine ganglions, without counting the brain; but the two first and the two last are so approximated that they may be reduced to seven. The second and the six following furnish the nerves to the seven pairs of feet; the four anterior feet, although analogous in the order of succession of the parts to the four last jaw-feet of the *Decapods*, are really feet, properly so called. The segments which immediately succeed, or those that form the tail, receive their nerves from the last ganglion. These segments may be considered as simple divisions of a single segment, represented by that ganglion; and we accordingly see that the number of these posterior segments varies.

The following is the arrangement of M. Latreille:—

The order consists of six sections.



1. *Epicarides.* (Latreille.)

These are parasitical Isopods, which, according to M. Latreille, are without either *eyes* or *antennæ;* the males however have eyes, though the females are blind. The *body* is flat, very small and oblong in the males; but much larger in the females, taking, in their case, the form of an oval, which is narrowed and a little curved posteriorly, hollow below, with a thoracic border, divided on each side into five membranous lobes. On this border the *feet*, which are very small and unfit either for walking or swimming, are situated. The under part of the *tail* is furnished with five pairs of small ciliated imbricated leaflets, answering to as many segments, and disposed in two longitudinal rows; but the posterior extremity is deprived of appendages. The *mouth* presents distinctly only two membranous leaflets applied one upon the other, of the same consistence, and quadrilateral. The lower concavity, forming a sort of flat basket, is filled with eggs. Near the place of their issue is constantly found an individual, which is presumed to be the male; but M. Latreille adds, that the extreme smallness of its size seems to forbid the possibility of copulation. According to M. Desmarest, this individual is furnished with two eyes; its body is straight and nearly linear. One subgenus only belongs to this section.

Bopyrus. (Latreille.)

The most common species is *Bopyrus Crangorum.* Those who are in the habit of eating prawns will probably have observed a tumour occasionally presenting itself under the carapace on one of the sides, which is bulged out. On lifting this part of the shell, the parasite will, in such cases, be discovered immediately under it and upon the branchiæ. We have frequently detected the *Bopyrus*, but on whatever species of prawn it has been found, we have never remarked that the animal to which it adhered was more meagre than its fellows, though this perhaps may have arisen from the prawn not having been long subject to the visitation of the parasite. But there is another reason why the prawn should not suffer much from the adhesion of the parasite. The author of *Horæ Entomologicæ* informs us that he has lately found three specimens of *Bopyrus* (females) with their backs turned to the branchiæ of the prawns; and he is of opinion that they and other crustaceous parasites which adhere to the anterior parts of fishes and crustaceans fix themselves there for the sake of the currents (produced by the branchiæ in respiration), which bring with them the animalcules on which the parasites feed.

Bopyrus is found on *Palæmon serratus* and *Palæmon squilla*, but most frequently on the former. (See the paragraphs at the end of the account of *Serolis*.)

Bopyrus Crangorum.

a, The upper side; *b*, the animal seen in profile; *c*, the under side; *d*, one of the feet, much magnified (female); *e*, small individual, considered as the male, upper side; *f*, the same, lower side; *g*, carapace of a prawn deformed on the right side by the presence of *Bopyrus*. (Desmarest.)

M. Risso has described another species, under the female of which he states that he found eight or nine hundred living young ones. See further, Desmarest, *Considérations sur les Crustacés*, p. 324.

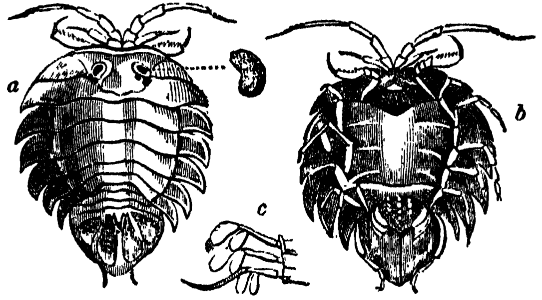
2. *Cymothoada.* (Latr.)

This section comprises those Isopods which have four

very apparent *antennæ;* these are setaceous, and nearly always terminated by a pluriarticulate stem. These crustaceans have *eyes*, a *mouth* of the ordinary formation (Latreille refers to the generalities of the *Malacostraca* with sessile eyes), vesicular *branchiæ*, disposed longitudinally in pairs, a *tail* consisting of from four to six segments, with a fin on each side, and the anterior *feet* most frequently terminated by a strong but small nail or hook. These Isopods are all parasitic according to Latreille; but *Serolis* appears not to be a parasite. Sometimes the eyes are mounted on tubercles at the summit of the head. The tail is composed of only four segments.

Serolis. (Leach.)

One species only known (*Cymothoa paradoxa* of Fabricius). *Antennæ* placed on two lines, and terminated by a pluriarticulate stem. Under the three first segments of the *tail* there are between the ordinary appendage three others, which are transverse and terminated posteriorly in a point.



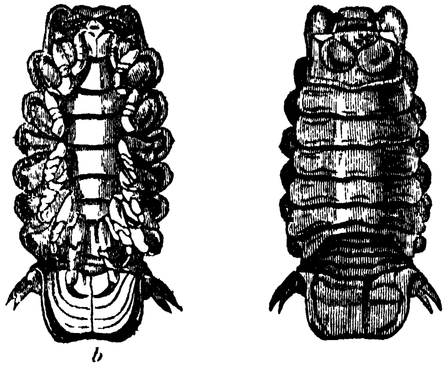
M. Desmarest describes the animal thus:—superior *antennæ* formed of four joints, larger than the three first of the inferior antennæ; the last joint composed of many others, and smaller. Inferior antennæ with five joints, the two first small; the third and fourth (principally this last) elongated; the fifth composed of many others, smaller. Second pair of *feet* having the penultimate joint enlarged and the nail or claw much elongated; the sixth pair ambulatory, rather spiny, and having the nail slightly curved. Anterior appendages of the belly, or *branchial laminæ*, formed of two equal parts, which are foliaceous, rounded at their extremity, furnished with hairs at their base, placed upon a common peduncle; the two posterior and lateral appendages small and narrow, especially the interior one, which hardly projects.

This is a very interesting animal, and has been considered to offer some resemblance at first sight to the extinct form of the *Trilobites.* M. Desmarest however remarks that it requires but a slight examination to prove that there is not the slightest resemblance between them.

Dr. Buckland, on the other hand, is of opinion that *Serolis* affords the nearest approach among living animals to the external form of Trilobites. The most striking difference, he observes, between this animal and the *Trilobites* consists in there being a fully developed series of crustaceous legs and antennæ in *Serolis*, whilst no traces of either of these organs have yet been discovered in connexion with any *Trilobite.* M. Brongniart, he adds, explains the absence of these organs by conceiving that the *Trilobites* hold precisely that place in the class Crustaceans (*Gymnobranchia*) in which the antennæ become very small or altogether fail; and that the legs, being transformed to soft and perishable paddles (*pattes*), bearing branchiæ, or filamentous organs for breathing in water, were incapable of preservation.

It is however by no means clear that we have in *Serolis* the nearest approach to those extinct crustaceans so interesting to the geologist and palæontologist. Do we not find a much nearer approximation in *Bopyrus?* Of this opinion is Mr. W. S. MacLeay, the author above quoted, who has perhaps studied the *Invertebrata* with a view to generalization more deeply than any living zoologist. The *Trilobites* exhibit no vestige of antennæ: *Serolis* has antennæ; *Bopyrus* has none; nor are we to forget the rudimentary legs of the latter. In accordance with this view the male of *Bopyrus* would represent a sort of *Bumastus* (Murchison, *Silurian System*), and the female an *Asaphus.* If this supposition be well founded, those forms among the Trilobites which systematists have separated specifically on the ground of the absence or presence of eyes, may be mere modifications arising from sexual difference; for nature makes nothing in vain; and the females of *Bopyrus* and *Cymothoa* have no eyes, because they do not require them, whilst the males do. Thus the cochineal-insect, when young and locomotive, has eyes; but the female, when fit for reproduction, becomes a fixture and is blind. So the Cirrhipeds in their youth are free and have eyes; in their adult state, when they are sessile, they lose organs which would be comparatively useless.

With regard to the observation of M. Brongniart, the softness of the texture of the *Nereidina* of MacLeay, and the perfection of the impression of *Nereites Cambrensis*, Murch. (pl. 27, *fig.* 1, of Mr. Murchison's work 'On the Silurian System of Rocks'), make it very remarkable, as Mr. MacLeay there observes, that if articulated feet existed in the Trilobites, some vestiges of them, even although membranaceous, should not come down to us more perfect than those figured by Goldfuss. [TRILOBITES.]



Serolis Fabricii. *a*, back; *b*, under surface, showing the union of crustaceous legs with the membranous branchiæ; *c*, magnified view of branchiæ.

Locality of the genus.—Tierra del Fuego, Straits of Magalhaens (Banks). Senegal (Dufresne). Captain Phillip Parker King, R.N., collected many specimens on the east coast of Patagonia, and also at Port Famine, in the Straits, where Capt. King saw the beach covered with dead specimens. He also observed them alive swimming close to the bottom among the sea-weed. They moved slowly and gradually, unlike a shrimp. He never saw them swimming near the surface: their legs seemed adapted for swimming and crawling on the bottom.

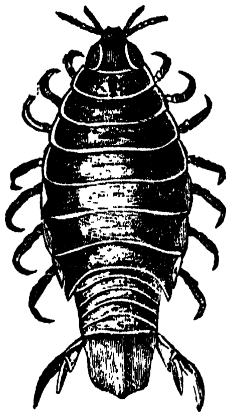
Cymothoa. (Fabr.)

Antennæ nearly equal in length; *eyes* but little apparent; last segment of the *tail* squared, and the two pieces terminating the lateral fins linear, equal, and styliform.

Cymothoa œstrum. *a*, upper side; *b*, lower side.

Ichthyophilus (Latr.; *Nerocila, Livoneca*, Leach).

Antennæ of equal length, and *eyes* not very visible; last segment of the *body* nearly triangular, with two pieces terminating the lateral fins, in form of leaflets or blades: the exterior of these is greatest in *Nerocila*, and of the same size as the others in *Livoneca.*

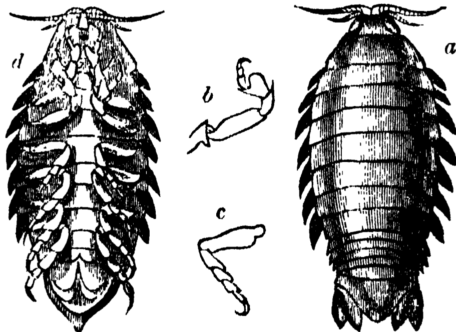


M. Latreille observes that in the four following subgenera the superior *antennæ* are manifestly shorter than the inferior.

Many, as well as the *Cymothoæ*, have all the *feet* terminated by a powerful and strongly arched nail (onglet); the last eight are not spiny; the *eyes* are always distant and convex. These, in the method of Dr. Leach, form three genera, but M. Latreille is of opinion that they may be united under one subgenus, namely,

Canolira (Leach; *Anilocra, Olencira*, of the same).

In those *Canoliræ* designated by Dr. Leach as *Olenciræ* the *blades of the fins* are narrow and armed with points. In those named by the same zoologist *Anilocræ* the external blade of the fins is longer than the internal one; the inverse of which is the case with the *Canoliræ*, in which, besides, the *eyes* are but very little granulated, while they are very sensibly granulated in *Anilocra.*



M. Latreille remarks that in the three following subgenera the second, third, and fourth *feet* only are terminated by a very strongly curved nail (onglet), and the eight last are spiny. The *eyes* ordinarily have but little convexity, and are large and converging anteriorly.

Canolira (Anilocra) Capensis.

Æga. (Leach.)

Two first joints of the superior *antennæ* very large and compressed.

Æga emarginata.
a, upper side; *b*, anterior foot; *c*, posterior foot; *d*, under side.

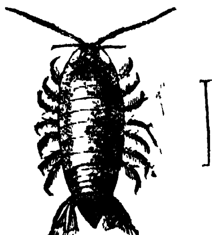
Rocinella. (Leach.)

Two first joints of the superior *antennæ* nearly cylindrical, but approaching the *Ægæ* in their large and anteriorly approximated *eyes*.

Conilira. (Leach.)

Antennæ as in *Rocinella;* but the *eyes* are small and distant; and the edges of the segments are nearly straight, and not falciform and prominent.

Synodus. (Latr.)



Antennæ upon two lines, lower *antennæ* always short, tail of six segments; distinguished from all the preceding by their great and projecting jaws. Only one species.

Cirolana. (Leach.)

Length of the lower *antennæ* surpassing the half of that of the body. Six segments in the *tail*.

Nelocira. (Leach.)

Length of lower *antennæ* as in *Cirolana*. Five segments only in the *tail*. *Cornea* of the eyes smooth.

Nelocira Swainsonii.

Eurydice. (Leach.)

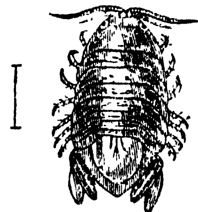
Resembling *Nelocira* in the number of the caudal segments, but differing from that form in its granulous *eyes*.

M. Latreille is of opinion that this subgenus conducts us to those whose *eyes* are formed of small grains, or which have those organs smooth, and which have besides the four *antennæ* inserted upon the same horizontal line, consisting of four joints at most, all the *feet* ambulatory, and the *tail* composed of six segments. Such a form is

Limnoria. (Leach.)

The only living species known is *Limnoria terebrans*, which, although only two lines in length, is nevertheless highly injurious in consequence of its multiplication and its habits. The rapidity with which this crustacean pierces the timber of ships makes its attacks not only mischievous but alarming. It rolls itself up like a wood-louse when it is seized; and is a native of the European Seas.

3. *Sphæromides.* (Latr.)



The Isopods composing this section have four very distinct *antennæ*, which are either setaceous or conical; and, with the exception of *Anthura*, they are always terminated by a stem divided into many small joints, and short. The lower antennæ, which are always the longest, are inserted under the lower part of the first joint, which is large and thick. The *mouth* has the usual form. The *branchiæ* are vesicular or soft, naked, and disposed longitudinally in pairs. The *tail* has only two complete and moveable segments, but has often impressed transverse lines upon it, indicating the vestiges of other segments. On each side of its posterior extremity is a fin terminated by two leaflets, the lower of which is moveable, while the upper one is formed by an internal prolongation of the common support. The *branchial appendages* are curved internally; the internal side of the first is accompanied in the males by a small linear and elongated piece. The anterior part of the *head*, situated below the *antennæ*, is triangular, and in the form of a reversed heart. Some have an oval or oblong *body*, contracting ordinarily into the form of a bowl. The *antennæ* are terminated by a pluriarticulate joint, and the lower ones at least are sensibly longer than the head. The lateral and posterior fins are formed of a peduncle and two blades, composing, together with the last segment, a fan-like fin. In these the impressed and transverse lines of the anterior segment of the *tail*, always shorter than its successor, or the last, do not reach the lateral borders. The first joint of the superior antennæ is in the shape of a triangular battledore (palette). The *head* seen from above forms a transversal square. The leaflets of the fins are very much flattened, and the intermediate piece, or last segment, is enlarged and rounded laterally.

Zuzara. (Leach.)

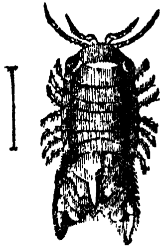
Leaflets of the *fins* very large, the upper of which is shortest, separated from the other to form a border to the last segment.

Sphæroma. (Latr.)

Leaflets of moderate size, equal, and applied one over the other.

Sphæroma dentata.

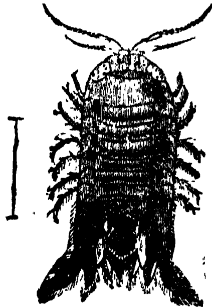
In others the impressed lines, or transverse sutures of the anterior segment of the *tail*, attain the lateral border and cut it. The first joint of the superior *antennæ* forms an elongated *palette*, which is square or linear. The leaflets of the *fins* are ordinarily narrower and thicker than in the preceding: the exterior sometimes (as in *Cymodocea*) envelops the other: their point of junction resembles a knot or joint. Sometimes the sixth segment of the *body* is sensibly longer than the preceding segments and the succeeding one. One of the leaflets of the fins only is projecting.



Næsa (Campecopæa, Leach).

Næsa bidentata.

Sometimes the sixth segment of the *body* is of the length of the preceding segments, and of the succeeding one, as in



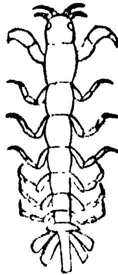
Cilicœa, where one of the leaflets of the fins only is projecting, the other leaning against the posterior border of the last segment.

Cilicœa Latreilli.

Cymodocea. (Leach.)

In this form the leaflets of the *fins* are projecting and directed backwards. The sixth segment is not prolonged posteriorly, and the extremity of the last segment has a small blade in a notch.

Cymodocea Lamarckii.



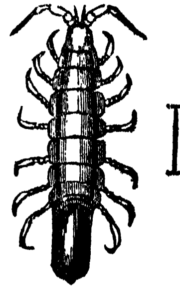
Dynamene.

Resembling *Cymodocea* in the projection and direction of the leaflets of the fins, but having the *sixth segment* prolonged backwards, and the last with a simple slit only, there being no blade.

Others again, as

Anthura,

have a vermiform *body*, and the *antennæ*, hardly so long as the head, consisting of four joints. The leaflets of the posterior *fins* form by their disposition and approximation a sort of capsule. The anterior *feet* are terminated by a monodactyl claw.

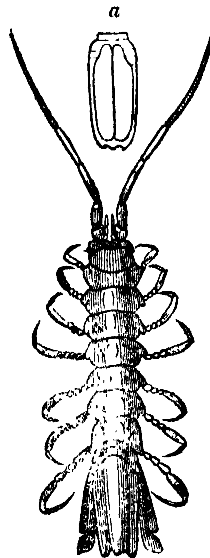


Anthura Gracilis, magnified.

4. *Idoteidæ*. (Leach.)

This section consists of Isopods whose *antennæ* are four in number, but upon the same horizontal and transverse line; the lateral ones are terminated by a stem ending in a point, gradually decreasing and pluriarticulate; the intermediate antennæ are short, filiform, or a little the largest towards the end, and four-jointed, none of the joints being divided. The conformation of the *mouth* is the same as in the preceding sections. The *branchiæ* are in the form of bladders, white in the greater part, susceptible of being blown up, capable of aiding in swimming, and covered by two blades or valvules of the last segment, adhering laterally to its borders, longitudinal, biarticulate, and opening in the middle by a straight line, like a folding door. The *tail* is formed of three segments, the last of which is much the largest, without appendages at the end or lateral fins. These crustaceans are all marine.

Idotea. (Fabr.)



All the *feet* strongly unguiculated and identical; the *body* oval or simply oblong, and the lateral *antennæ* shorter than the half of the body.

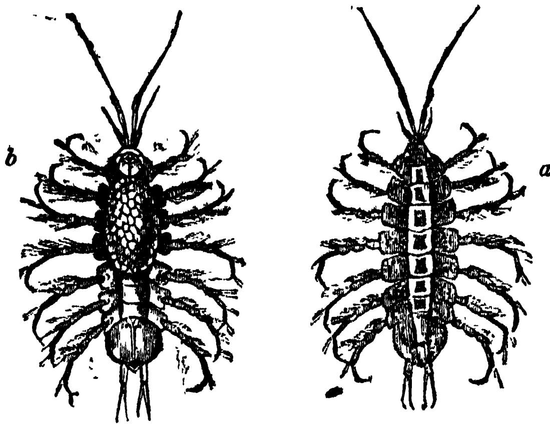
Idotea tricuspidata.

Stenosoma. (Leach.)

Differing from *Idotea* in the linear form of the *body* and the length of the *antennæ*, which surpasses the half of that of the body.

Stenosoma lineare, natural size. *a*, laminæ of the under part of the abdomen.

Arcturus. (Latr.)



Very remarkable for the form of the second and third *feet*, which are directed forwards, and terminate by a long bearded joint, unarmed or feebly unguiculate; the two anterior feet are applied upon the mouth and unguiculated; the six last are strong, ambulatory, thrown backwards, and bidentated at their extremity. In the length of the *antennæ* and form of the body *Arcturus* approaches *Stenosoma*. M. Latreille (1829) says that he never saw but one species, *Arcturus tuberculatus*, brought home from the North Seas by one of the last English expeditions to the North Pole.

5. *Asellota*. (Latr.)

The fifth section consists of Isopods with four very apparent *antennæ* which are disposed on two lines, and are setaceous and terminated by a pluriarticulate stem. There are two *mandibles*, four jaws, ordinarily covered by a species of lip formed by the first *jaw-feet*. The *branchiæ* are vesicular, disposed in pairs, and covered by two longitudinal and biarticulate but free leaflets. The *tail* is formed of a single segment, without lateral fins, but with two bifid needle-like processes, or two very short appendages in the form of tubercles, at the middle of its posterior border. There are other lamellar appendages situated on its inferior base, more numerous in the males than in the females, and these serve to distinguish the sexes.

Asellus. (Geoffroy.)

Two bifid needle-like processes at the posterior extremity of the *body*; *eyes* distant; superior *antennæ* at least as long as the peduncle of the inferior antennæ. Hooks at the end of the feet entire

Asellus aquaticus (Idotea aquatica, Fabr.), female, magnified. *a*, upper side; *b*, under side.

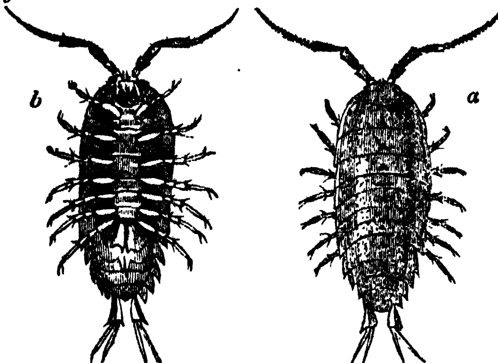
This is very abundant in fresh stagnant waters, as in the pools about Paris. It moves slowly when not terrified. In the spring it comes forth from the mud, in which it has passed the winter. The male, which is much larger than the female, carries her about for a space of eight days, holding her by means of his fourth pair of feet. When he quits her, she is pregnant with a great number of eggs, enclosed in a membranous sac placed under her breast, and opening by a longitudinal slit to give passage to the young.

Oniscoda. (Latr.)

These, the *Janiræ* of Dr. Leach, differ from the *Aselli* in the approximation of their *eyes*, in having their superior *antennæ* shorter than the peduncle of the inferior ones, and in the hooks of the *tarsi*, which are not bifid. M. Latreille remarks that the only species known (*Janira maculosa* of Leach) has been found on the coasts of England among the sea-weeds and *Ulvæ*.

Jæra. (Leach.)

This form, in the place of the needle-like processes (stylets) at the end of the *tail*, has only two tubercles. M. Latreille remarks that only a single species, *Jæra albifrons*, Leach, has been found, and that it is very common on the English coast, under stones and among the sea-weed.



6. Cloportides, *Oniscidæ*. (Latr.)

This, the last section of Isopods, according to the arrangement of M. Latreille, consists of those forms which have indeed four *antennæ*, but the two intermediate ones are very small, little apparent, and consist of two joints at most: the lateral antennæ are setaceous. The *tail* is composed of six segments, with either two or four needle-shaped appendages at the posterior border of the last segment, and without lateral fins. Some are aquatic, others terrestrial. In the latter, the first leaflets below the *tail* exhibit a row of small holes, where the air penetrates to the organs of respiration there enclosed.

Some have the sixth joint of their *antennæ*, or their stem, so composed that in counting the small articulations of this part the total number of all the joints is nine at least. These are marine, and consist of two subgenera.

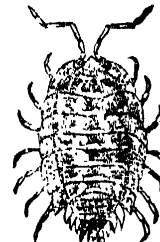
Ligia. (Fabr.)

Stem of the lateral *antennæ* composed of a great number of small joints, and two very projecting *stylets*, separated at the end into two branches, at the posterior extremity of the *body*.

Ligia Oceanica, nat. size. *a*, upper side; *b*, under side.

This is very common on the sea-coast, where it may be seen creeping on the rocks or on sea-walls. When an attempt is made to seize it, the animal quickly folds its feet and lets itself drop.

Tylos. (Latr.)



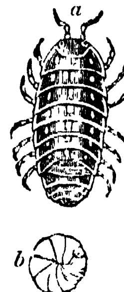
These seem to have the faculty of rolling themselves up. The last segment of the body is demicircular, and exactly fills the notch formed by the preceding. The posterior appendages are very small and entirely inferior. The *antennæ* have only nine joints, the four last of which compose the stem. On each side is a tubercle representing one of the intermediate antennæ; the intermediate space is elevated. The *branchiæ* are vesicular, imbricated, and covered by laminæ. Example, *Tylos Armadillo*. Locality, Mediterranean.

Philoscia. (Latreille.)

Lateral *antennæ* divided into eight joints and exposed at their base. The four posterior appendages nearly equal. These occur in moist places. Example, *Oniscus sylvestris*, Fabr.

Cloportes, properly so called; Oniscus, Linn. (Wood-Lice).

Eight joints to the lateral *antennæ*, but their base is covered; and the two external appendages of the *tail* are much larger than the two internal ones. These animals frequent dark and retired places, such as caves, cellars, holes in walls, &c., and are also found under stones and old logs. Their food consists of decayed vegetable and animal substances; and they scarcely ever come forth from their retreats except in rainy or moist weather. They move slowly when not in danger. The *eggs* are enclosed in a pectoral pouch. The young at their birth have a thoracic segment short, and consequently only twelve feet. These crustaceans were formerly used in medicine; but they no longer form part of the *materia medica*.



Oniscus murarius.

Porcellio. (Latr.)

Distinguished from the true wood-lice by the number of joints of their lateral *antennæ*, which are only seven. In other respects *Porcellio* resembles *Oniscus*.

Armadillo. (Latr.)

The posterior appendages of the *body* are not projecting; the last segment is triangular. A small blade, in form of a reversed triangle, or more large and truncated at the end, formed by the last joint of the lateral appendages, fills up on each side the void between the segment and the preceding. Lateral *antennæ* with only seven joints. The upper *subcaudal scales* are pierced with a row of small holes.

Armadillo pustulatus. *a*, expanded; *b*, rolled up.

Such is the arrangement of M. Latreille.

Lamarck divided the *Isopoda* into two great sections: the first consisting of those Isopods which have the *branchiæ* situated under the *tail*, and comprising two subdivisions; the second composed of those which have their *branchiæ* placed under the anterior part of the *abdomen*, between the *feet*.

Under the first he arranged the genera *Armadillo*, *Onis-*

cus, Philoscia, Ligia, Asellus, Idotea, Sphæroma, Cymothoa, Bopyrus, Typhis, Anceus, Praniza, Apseudes, Ione.

Under the second he included the genera *Leptomera, Caprella,* and *Cyamus.*

M. Desmarest divided the *Isopoda* into two great sections, with many subdivisions.

His first section, which he makes equivalent to the *Phytibranchiate Isopods* of Latreille, consists of the genera *Typhis, Anceus,* including *Gnathia* of Leach, *Praniza, Eupheus,* and *Ione.*

His second section, which he makes equivalent to the *Ptérygibranches* of Latreille, comprises the genera *Idotea, Stenosoma, Anthura, Serolis, Campecopea, Næsa, Cilicæa, Cymodocea, Dynamene, Zuzara, Sphæroma, Eurydice, Nelocira, Cirolana, Conilera, Rocinella, Æga, Canolira, Anilocra, Olencira, Nerocila, Livoneca, Cymothoa, Limnoria, Asellus, Janira, Jæra, Ligia, Philoscia, Oniscus, Porcellio, Armadillo,* and *Bopyrus.*

M. Milne Edwards (edition of Lamarck, 1838) states, in a note to that part of Lamarck's definition of an Isopod crustacean, '*mandibules. sans palpes,*' that Lamarck, Latreille, and most authors are in error when they assign this character to the Isopods, for in a great number of these crustaceans the mandibles are provided with a palpiform stem, entirely resembling that which may be seen in the greater part of the *Amphipoda.*

He further remarks that the respiratory lamellæ situated under the abdomen are hardly ever *branchiæ,* properly so called, but only one of the branches of the *false feet* become membranous and vascular, as in one of the appendages of the *thoracic feet* in the *Amphipoda.* The female of *Ione,* he observes, exhibits an exception, for she carries ramose *branchiæ* on each side of the abdomen.

M. Milne Edwards, in his notes, further states that those crustaceans whose respiratory appendages are placed under the *thorax* (which Lamarck calls *abdomen*) ought not to remain in the order of *Isopoda,* but belong to the *Læmodipoda* of M. Latreille. The *egg-pouch* he describes as being formed of the flabelliform appendages, which have become foliaceous, and are raised against the sternum.

The same acute zoologist (*loc. cit.*) says that the *Isopoda,* properly so called, are *Edriophthalmous crustaceans,* whose abdomen is never rudimentary, and carries below five pair of false *branchial feet,* having all nearly the same form and the same functions. The appendages of the penultimate ring (or the false feet of the sixth pair) have a form and use different from those of the preceding. The *thorax,* composed in general of seven rings, but sometimes having only five, carries nearly always seven pair of feet, which are often furnished with a foliaceous palp, serving to protect the eggs and young, but they hardly ever carry a vesicular appendage proper for respiration, as in the *Amphipoda* and *Læmodipoda.* Finally, the conformation of their buccal apparatus varies, and the greater part of authors are in error when they assign to them as a character the possession of mandibles deprived of palpiform appendages.

M. Milne Edwards is of opinion that the *Isopoda* form three natural families, namely, the *Idoteidians,* the *Cymothoadians,* and the *Cloportidians,* and he thus distinguishes them.

A. Jaw-feet operculiform, and deprived of a palpiform stem, or only showing the vestiges of it.

* Thoracic feet ambulatory; last segment of the abdomen smaller than the preceding segments; internal antennæ rudimentary.

These form the family of

Cloportidians.

* Thoracic feet anchor-like (ancreuses), last segment of the abdomen nearly always much larger than the preceding segments; internal antennæ in general well developed.

These form the family of

Cymothoadians.

AA. Jaw-feet palpiform. Last abdominal ring much more developed than the preceding ones; all or nearly all the feet ambulatory.

These form the family of

Idoteidians.

In this classification, says the author, the family of the *Cloportidians* has the same limits as in the method adopted by Lamarck, and comprises the *Terrestrial Isopods.*

The family of *Cymothoadians* is composed of the *Parasitic Isopods,* and comprehends *Cymothoa* of Lamarck, *Ione, Anceus,* and *Typhis.*

The family of *Idoteidians* consists of *Marine Isopods not Parasitic,* and embraces the genera *Idotea, Sphæroma, Anthura, Asellus,* &c.

Our limits will not allow us to go further into the valuable observations of M. Milne Edwards; and we must refer the reader to the fifth volume of the new edition of Lamarck for them. His highly interesting work, *Histoire Naturelle des Crustacés,* has not yet proceeded so far as the *Isopoda,* but we learn from it that he places them, together with the *Amphipoda* and *Læmodipoda,* under the legion of *Edriophthalmia.* [CRUSTACEA, vol. viii., p. 197.]

FOSSIL ISOPODA.

M. Latreille states that Professor Germar had sent to M. le Comte Dejean the figure and description of a small fossil crustacean which appeared to him (M. Latreille) to be referrible to the subgenus *Limnoria;* and he further remarks that *Oniscus prægustator,* figured in Parkinson's work, comes near to that species, or at least appears to belong to the same section.

M. Desmarest (*Histoire Naturelle des Crustacés Fossiles*) enumerates two fossil species of the genus *Sphæroma:* one, *Sphæroma antiqua,* found in a fragment of white, fine-grained calcareous stone, analogous in that respect to the Pappenheim stone, but of which he knows not the origin; the others, *Sphæroma Margarum,* from the horizontal beds of green fissile marl (*marne verte fissile*) at Montmartre, above the gypseous beds, mingled with *Spirorbes.*

The reader will find the TRILOBITES treated of in that article.

ISOPYRE, a mineral which occurs amorphous in granite. Fracture flat, conchoidal. Brittle. Hardness, 5·5 to 6. Colour velvet or greyish-black, occasionally dotted with red. Colour of streak greenish-grey. Slightly obeys the magnet. Lustre vitreous, Opaque or slightly translucent. Specific gravity 2·9 to 3. It is with difficulty acted upon by acids. Fuses before the blowpipe. It occurs in the granite of St Just, near Penzance, in Cornwall. According to Turner's analysis, it consists of

Silica	47·09
Alumina	13·91
Lime	15·43
Peroxide of iron	20·07
Oxide of copper	1·94
	98·44

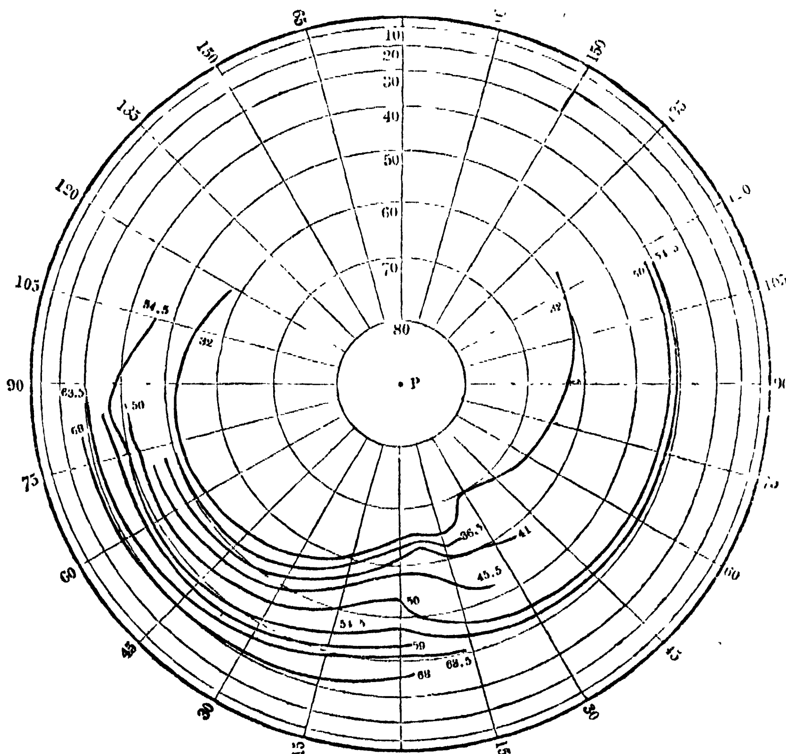
ISO'SCELES (ἴσος, equal, σκέλος, leg), a term applied to a triangle of which two sides (or legs) are equal.

ISOTHERMAL LINES are curves supposed to be traced on the surface of the earth so that each may pass through a series of points at which the mean annual temperature is the same. The situations of such points were first determined by M. Humboldt from the registers of observed temperatures in Europe, and from the numerous observations made by himself and other travellers in different regions of the world. A full account of the researches of this philosopher respecting the temperature of the atmosphere and the law of its variations, in connection with the subject of this article, is contained in the third volume of the 'Mémoires d'Arcueil;' and also in the 'Annales de Chimie et de Physique,' tom. v.

Curve lines connecting points of equal temperature in the interior of the earth have been called *Isogeothermal lines.*

The temperature of the air in any region depends on the inclination of the sun's rays to the surface of the earth in that region, on the distribution of land and water, on the state of the countries from which come the prevailing winds, on the vicinity of the sea, the elevation of the land, and numerous other circumstances; and the complexity of the subject is such as to render vain any attempt to assign a law for the actual heat at a given place. The mean annual temperatures of places remain however nearly constant, and their decrease, in going from the equatorial regions towards either pole, approaches near enough to uniformity to encourage the expectation that the precise law of that decrease may one day be discovered.

Professor Mayer of Göttingen appears to have been the first who attempted, from such observations as existed in his time, to express the law by a formula. He made the temperature on any parallel of terrestrial latitude to depend on



the square of the cosine of the latitude, and with some modifications this law is even now generally admitted. At the level of the sea the value of the mean annual temperature is expressed by $M + E \cos. 2L$; where L is the latitude of the place, M is the mean temperature on the parallel of 45°, and $M + E$ is that at the equator; and Professor Playfair has from this expression deduced a formula for temperature which includes the season of the year and the elevation of the place above the sea: he admits however that it agrees only with the Atlantic Ocean and the western part of the Old Continent. (*Outlines of Nat. Phil.*, 'Pneumatics.')

In the northern hemisphere, as we proceed eastward and westward from the meridians of Greenwich or Paris, it is found that the mean temperature of any parallel becomes continually less, and the severity of the winter greater than in this part of the world; the difference appears to attain a maximum at the eastern extremity of Asia, and one still higher in the central parts of North America. From a comparison of observations Humboldt found that between the parallels of 28° 25′ N. and 41° 53′ N. the difference between the latitudes of a place in Europe and a place in North America, having the same mean temperature, is about 7 degrees; and that the difference between the mean temperatures of two places having the same latitude in Europe and North America is 4·1° of Fahrenheit's thermometer.

In order to ascertain with the utmost possible precision the mean temperature of any place from the tables there kept, Humboldt divided the sum of all the temperatures observed in each day at intervals of one hour by the number of observations; and the sum of all these mean daily temperatures being divided by 365, gave the mean annual temperature. And in determining the series of points for his lines of equal temperature, when there existed no observations on which he could depend, he interpolated the temperature and geographical position between the values of those elements at two or more places where they were well known.

The period during which a traveller remains in any one place will seldom allow him to make a sufficient number of observations for determining its mean annual temperature by the process above mentioned; and therefore it may be useful to know that, according to Humboldt, the mean temperatures for the months of October and April are very nearly equal to the annual mean temperature; also that the half sum of the temperatures at sun-rise and at 2 P.M. is nearly equal to the mean temperature for the day. It may be proper to remark also that travellers, in making observations relating to temperature, should be careful to place their thermometers at some distance above the surface of the ground, and in situations where they may be unaffected by the reflection or radiation of heat from buildings or from terrestrial particles in the atmosphere. The very high temperatures which have been occasionally observed in sandy deserts are probably owing in part to the latter circumstance.

The following diagram represents an orthographical projection, on the plane of the equator, of the principal meridians and parallels of latitude in the northern hemisphere of the earth; and the strongly marked curves represent the nine isothermal lines whose forms have been determined by Humboldt. Their distances from one another are such as correspond on the earth to a change of mean annual temperature equal to 2·5 degrees of the centigrade thermometer (4·5° of Fahrenheit), and the most northern curve is that on which the mean temperature is expressed by zero on the former, or 32° on the latter scale. The number on each curve in the diagram expresses, according to Fahrenheit's thermometer, the mean annual temperature, at the level of the sea, of all the places through which the curve passes. The centre P represents the pole of the earth, and the longitudes of the meridian lines are numbered eastward and westward from the meridian of Greenwich.

The isothermal line of 32° passes about 4 degrees southward of Nain, a Moravian settlement on the coast of Labrador; and, continuing eastward through a point about 1 degree north of Umea in Sweden, it there makes a remarkable inflexion. After ascending as high as North Cape in Lapland it abruptly returns southward, and attains its lowest limit in the eastern parts of Asia. Proceeding westward from Labrador recent observations have shown that the curve descends towards the south and crosses the lower extremity of Hudson's Bay, from whence it again tends northwards to the Great Slave Lake. The positions of the other curves seem to be influenced in some measure by that which has been just mentioned. In their progress from the western coast of Europe to the eastern coast of America they incline towards the terrestrial equator, yet so that the southern curves approach very near to parallelism with that great circle of the earth. Within the territory of the United States they assume a form which is convex

to the equator, and farther west they appear to re-ascend towards the north. At about 10° eastward of the meridian of Greenwich the curves have their convexities turned northwards; and farther eastward they descend towards the equator, but the want of accurate observations in Asia renders their course in that part of the world rather uncertain. The isothermal line of 54·5° alone has been traced nearly round the earth: commencing at the mouth of the Columbia, on the western coast of North America, it passes near the city of Washington with its convexity towards the south; and after crossing the Atlantic it runs through Bordeaux, from whence it continues to the city of Pekin, at which place it again becomes convex towards the equator. It may be added that by the late voyages into the Arctic seas two points have been determined in the isothermal curve of 17°, which appears to pass through Spitzbergen in lat. 78° N., and through Melville Island in lat. 65° N.

But in every country the mean temperature varies with the height of the place above the level of the sea; and Humboldt, from observations made as well on the Cordilleras as in Europe, having determined that at every 100 metres of elevation (or 328 English feet) the mean temperature of the air is diminished by a quantity equal to that diminution which is consequent on an augmentation of latitude equal to one degree, calculated a table of the corrections which should be made in the curvatures of the isothermal lines at the level of the sea, in order to obtain the forms of those which appertain to points at any given elevation. According to Playfair the diminution of heat on ascending in the atmosphere is, near the surface of the earth, at the rate of 1° (Fahr.) for every 270 feet; but Mr. Atkinson, in the 'Memoirs of the Royal Astr. Soc.,' vol 2, from a comparison of many observations, makes the diminution equal to 1° for every 251·5 feet. He has also shown that the differences of temperature between summer and winter begin to diminish at the height of about 21,000 feet above the surface of the earth.

The differences between the mean summer and mean winter temperatures are very considerable at places whose mean annual temperature is the same; and these differences are not equal in the Old and New Continent. On the isothermal line of 32° in Europe, that difference is equal to 39·6°, and in America to 54°; and on the isothermal line of 68° the differences are respectively 21·6° and 27°. It has also been remarked that the differences between summer and winter are least near the northern, and greatest near the southern bends of the curves.

The curves formed by connecting, on the isothermal lines, points at which the mean temperature of summer is the same are called *isotheral* lines; and those formed by connecting points at which the mean winter temperature is the same are called *isocheimal* lines: both these systems of lines deviate more than the isothermal lines from the parallels of terrestrial latitude.

It was long supposed that the mean temperature of the southern was much lower than that of the northern hemisphere. In fact, in the Arctic seas, large masses of floating ice are not found below the 70th degree of latitude, and permanent fields exist only beyond the latitude of 75 or 80 degrees; while in the Antarctic regions ice is found in both states between the 54th and 59th degrees of latitude: and the island of Georgia, which is there situated, is perpetually covered with snow down to the sea-shore; whereas in the northern hemisphere this circumstance does not take place till we arrive at the parallel of 80°. [CLIMATE.]

The vast extent of the Antarctic seas, the absence of great tracts of land in those regions, and the pointed forms of the African and American continents, allow the currents to carry far northwards the ices of the southern pole; and thus a considerable degree of cold is produced at particular places. But the observations which have, within a few years, been made on the temperature of the southern regions, afford good reason to believe that there is little difference between the mean annual temperatures of places similarly situated in the two hemispheres. Near the equator, as might be expected, the mean temperatures in both are the same: those of the Isle of France and of Jamaica are 80·1°; the mean temperatures of Port Jackson, the Cape of Good Hope, and Buenos Ayres (66·7° to 67·5°), correspond to those of Natchez, Funchal, Algiers, and Cairo (64·8° to 72°). The mean temperature of the Malouine or Falkland Isles is 47·3°; at an equal latitude it is in Europe about 50°, and in America 36°; and the mean temperature of Van Diemen's Land is about the same as that of Italy. M. Humboldt concludes that, as far as the parallels of 40° or 50° of latitude, north and south, the corresponding isothermal lines are nearly equally distant from the equator; and with respect to America the mean annual temperature is greater in the southern than in the northern hemisphere. The variations between the mean temperatures at the opposite seasons of the year are much less in the former than in the latter at corresponding latitudes; in Van Diemen's Land the winters are said to be milder than at Naples, where the mean winter temperature is 46°, while the summers are colder than at Paris, where the mean summer temperature is 64·6°. And at Port Jackson the mean winter temperature (= 56·8°) corresponds to that of Cairo, while the mean summer temperature (= 77·4°) is equal to that of Marseilles.

M. Humboldt considers the mean annual temperature at the equator, at the level of the sea, to be equal to 81°·4 (Fahr.); but Mr. Atkinson (*Mem. of the Royal Astr. Soc.*, vol. ii.) found, by applying the method of least squares to equations formed from the data furnished by that philosopher himself, and assuming the temperature to vary, first as the square of the cosine, and then as $\cos.^{\frac{3}{2}}$ of the latitude, that the mean temperature there is at least equal to 84·5°. It is right to observe however, that Humboldt, in a paper published in the 'Annales de Chimie' for Sept., 1826, objects to the conclusions of Mr. Atkinson, and adheres to his own determination. Dr. (now Sir David) Brewster, in the sixth volume of the 'Edinburgh Journal of Science,' by a reduction of observations made at Ceylon, and assuming the temperature to vary according to the law of Mayer, finds 80·99° for the mean equatorial temperature.

An inspection of the isothermal curves, and particularly that of 32° in the above diagram, will sufficiently show that the mean temperature of the terrestrial pole cannot be obtained from any simple formula in which the variations are made to depend on the geographical latitudes of places. And in fact Captain Scoresby, using the formula of Mayer, and subtracting from the result a correction which he conceived to be due to the frigorific influence of the ice, made the mean temperature at the pole equal to 10° (Fahr.). From the observations of Captain (Sir Edward) Parry it appears that such temperature there must be lower than 3° below the zero of the scale. Sir D. Brewster has been led, from the form of the curves, to adopt the hypothesis of two polar points at which the mean temperature is a minimum: he places both of these on the parallel of 80° N. lat., but one of them is supposed to be situated in 95° E. long., with a mean temperature equal to + 1°, and the other in 100° W. long., with a mean temperature equal to − 3·5°; and, by inductions from observations, he has given, for the mean temperature at any place, the formulæ

$$81·8° \sin. D + 1°,$$
$$86·3° \sin. D - 3·5°;$$

where D is the distance of the place from the nearest pole.

By comparing the mean temperature at Van Diemen's Land with that at the Cape of Good Hope, the same philosopher concludes that in the Antarctic regions there are two points of maximum cold, whose situations correspond to those in the northern hemisphere. But it is evident that observations must be greatly multiplied in both hemispheres before the data can be considered sufficient for the determination of the isothermal equator or poles; or to serve as a foundation for the construction of formulæ for temperature in which full confidence may be placed.

In the 'Edinburgh Phil. Trans.,' 1820, Brewster has expressed the interesting idea that some connexion exists between the isothermal and the magnetic poles of the earth; in which case the revolutions of these last may produce corresponding revolutions in the others, and thus may serve to explain that augmentation of temperature which is supposed to have taken place in the west of Europe since the days of Cæsar and Ovid.

ISPAHAN. [PERSIA.]

I'SPIDA. [KINGFISHERS.]

ISRAEL, TRIBES OF. [JEWS.]

ISSOIRE. [PUY DE DOME.]

ISSOUDUN, a town in the department of Indre in France, on the River Theols, a tributary of the Arnon, which flows into the Cher; in 46° 57′ N. lat., 1° 59′ E. long.; about 130 miles in a direct line south by west of Paris, or 150 by the road through Montargis and Bourges. This town is

first noticed in the time of Louis IV., *Outremer* (A.D. 936-954). In the twelfth century it was under the dominion of lords of its own, to whom is ascribed the erection of its castle, of which only a large tower remains. In A.D. 1220 it was taken by Philippe II. *Auguste* from the English, and added to the domains of the crown. In the religious wars of the sixteenth century it came into the hands of the League, but A.D. 1589 the inhabitants drove them out. The town lost many inhabitants by the revocation of the edict of Nantes.

Issoudun is in a fertile tract, and is partly on the slope of a hill. The streets are broad and the houses built with tolerable regularity. There are four churches, two hospitals, a high-school, and a theatre. The population was, in 1831, 11,664; in 1836, 11,654: the inhabitants manufacture woollen cloth, linen, hosiery, earthenware, parchment, and leather; they trade in wine, wool, corn, and cattle: there are ten fairs in the year for cattle.

Issoudun is the capital of an arrondissement which comprehends 459 square miles, and had in 1836 a population of 47,572; it contains 4 cantons and 49 communes.

ISSUE is an ulcer artificially formed for the purpose of maintaining a constant purulent discharge from the body. It is usually made by placing one or more beads or peas on an incision through the integuments in one of the limbs, or in the neighbourhood of a diseased part, and there retaining them by adhesive plaster, so as to prevent the wound from healing, and keep it in a constant state of suppuration. Other issues are made by rubbing caustic potash, or potash and quicklime, on a part of the skin till it is destroyed and sloughs, and by keeping open the ulcer thus formed, either with peas, or very stimulant dressings. Setons are another form of issue, made by passing a broad flat needle beneath a portion of the skin, and retaining in the passage thus formed either a skein of silk or a flat band of caoutchouc. The moxa and the actual cautery are also sometimes employed with the same view.

The use of issues for the cure of constitutional diseases, under the idea that they remove noxious principles from the blood, is now entirely abandoned; but they are sometimes had recourse to in order to restore an habitual discharge which has been checked by the cure of any chronic local disease, and the cessation of which has seemed to give rise to congestion of the head or of any internal organ. But the principal value of issues is as counter-irritants, by establishing a disease which is of itself unimportant in the neighbourhood of one which by its situation is more serious; and hence they are amongst the most important means in the cure of chronic inflammations of many internal organs, and especially of those of the joints and of the spine.

ISSUE. (Law.) [PLEADING.]

ISSUS, BATTLE OF. [ALEXANDER III., p. 296.]

ISTHMIAN GAMES. These were one of the four great national festivals of Greece, the others being the Olympian, Pythian, and Nemean. They were celebrated under the presidency of the Corinthians, near Corinth, on the isthmus connecting Peloponnesus with the continent, and were celebrated at intervals of four years, corresponding with the recurrence of the other festivals abovementioned, so that each year had its solemnity. The Isthmian games were first established in honour of Melicertes, the son of Ino (Paus., i. 44); but were reorganized by Theseus in honour of Neptune, the presiding deity of the Isthmus. The crowns bestowed on victors were of pine leaves. As all these games were similar in their object and ceremonies, it will be sufficient to refer to the article on the principal of them, the OLYMPIAN GAMES.

ISTIO'PHORI, a family of Bats. [CHEIROPTERA, vol. vii., p. 22.]

ISTIU'RUS. This genus of Saurians, according to MM. Duméril and Bibron, includes the *Hydrosaurus* (*Hydrosaurus Amboinensis*) of Kaup. [IGUANIDÆ.]

I'STRIA, the antient Histria, a peninsula on the north-east coast of the Adriatic Sea, between the gulf of Trieste and that of Quarnero, or Fiume, is about 50 miles long from north to south, and about 40 miles across in its broadest part, ending in a point near Pola. Till the end of the last century Istria belonged to Venice, except the north-western part of it, or the territory of Trieste, which was in the possession of the House of Austria, but by the peace of Campo-Formio in 1797 the whole of it was given up by the French to Austria, together with the other territories of Venice. Istria now forms a circle of the government of Trieste, in the kingdom of Illyria. [AUSTRIA; ILLYRIA.] Its principal towns are Capo d'Istria, a bishop's see, with about 8000 inhabitants; Pirano, a place of considerable maritime trade, with fisheries, and about 6000 inhabitants; Rovigno, with 9600 inhabitants; and Pola, a decayed town, containing only a few hundred inhabitants, but remarkable for its fine remains of antiquity, such as an amphitheatre, several temples, one of which is dedicated to Augustus, a triumphal arch called Porta Aurea, &c. The antiquities of Pola have been described by Spon and by Cassas, 'Voyage Pittoresque de l'Istrie et Dalmatie,' with fine plates, fol., Paris, 1802. The population of Istria under the Venetian republic was 92,000 in 1789. The inhabitants of the towns and coasts are chiefly Italians, who speak a dialect of the Italian, but the peasantry and people of the interior are mostly of Sclavonian race, and speak a dialect of the Sclavonian language, like the Dalmatians and Croatians. The country produces oil, good wine, fruits, honey, corn, and silk; it is rich in salt and fisheries, and has abundant quarries of freestone and marble. It has some tanneries, and other manufactories, but in general the industry of the inhabitants is in a backward state. An offset of the Julian Alps, running to the eastward of Trieste, extends across to the shores of the gulf of Fiume, and sends out its arms into the body of the peninsula of Istria. On the southern slopes of this range several streams rise, which water the valleys of Istria.

ITALIAN ARCHITECTURE. To what was briefly said on this subject in the article CIVIL ARCHITECTURE, some further account is now added, which may be introduced by observing, that instead of comprising buildings of every style and class to be met with in Italy, the term 'Italian Architecture' is generally restricted to signify that generic style formed by the revival of the Roman orders, and the adaptation of them, and other features derived from works of the same age, to buildings of every kind, domestic as well as public. Without such limitation, the term would apply to buildings having nothing else in common than their locality, to the Ca d'Oro at Venice, no less than to the works of Palladio, and such modernized *Palladianism* as is exhibited in the design of the Teatro Fenice in the same city. Even with such limitation, the style presents so many varieties, both in regard to modes of treatment and taste of design, as to render it difficult to draw up a succinct account of it, if more be attempted than to explain the character of the orders and other leading external features, with their application, and the taste generally manifested in architectural design.

Instead of proposing to themselves the remains of Roman antiquity as models to be freely followed in the same spirit, and modified as circumstances should require, those who endeavoured to fix a new style founded upon the antient orders began by reducing the orders themselves to the strictest mechanical system possible; notwithstanding that for the Doric and Ionic they had no better guide than the few very debased and insipid specimens which occur in Roman works, and the ambiguous explanations given in the text of Vitruvius. Superstitiously taking him as an infallible oracle, they appear to have looked at the examples which Roman structures afforded them chiefly for the purpose of finding out how they might be made to correspond with his precepts and doctrines; whereas the more proper method would have been to have abided by the latter only so far as they were supported by the authority of the best actual examples. Yet if, on the one hand, this bigoted reverence for a writer who is frequently very obscure as well as pedantic, and who is moreover liable to be greatly misunderstood from the absence of visible representations of what he describes, led to the establishment of a most cramped, dry, and formal system in regard to every member of each order and its proportions; on the other, it did not deter from setting aside all classical precedent as respects almost every thing else in a building. Different orders, or repetitions of the same order, being applied to the several stories of buildings whose fronts were pierced with windows, it became unavoidably necessary to abandon all proportion of intercolumniation, and to space the columns according to the breadth of the piers and the apertures between them; which in turn left hardly any alternative than to engage the columns themselves, that is, to attach either half or three-quarter columns to the walls, because insulated columns placed so wide apart from each other would have had an exceedingly poor and meagre effect; and where

one order was placed above another, two straggling rows of low insulated pillars—for low they must be in comparison with the entire height—would have produced an appearance positively disagreeable, and instead of at all ornamenting a building, would have encumbered it with what would have resembled stages of scaffolding. Should any one question this, he has merely to fancy all the columns brought forward two or three feet, in the front of Whitehall chapel, and then judge whether it would be at all improved by two such sprawling galleries standing before it.

For a somewhat similar reason, either pilasters were substituted for engaged columns, or the entablature was made to break over every column,—as in the building just mentioned, which may be referred to as a tolerably characteristic specimen of Italian style in buildings of that class, without those capricious abnormities which so frequently offend us even in the buildings of Palladio himself, although he has the reputation of being comparatively chaste in his designs. For if, instead of being thus broken, the entablature were continued from column to column in each story, overhanging the face of the wall, it would produce the appearance of heaviness as well as weakness.

One defect attending this practice of giving a separate order to each story is, that the columns become insignificant, both in proportion to the entire front and to the windows between them, more especially when the columns are further shortened by being placed on pedestals. In fact windows and doors are generally the predominant features in Italian composition, even where two series are comprised within one order, being generally more prominent in their cornices and pediments than the other projections. They are often decorated with smaller columns or pilasters (as in the front of the Atlas Fire Office, Cheapside, and that of the Legal Assurance Office, Fleet Street), and Palladio has sometimes loaded them by recumbent figures on the raking cornices of their pediments. Sometimes, as in the upper order of the Procuratie Nuove, by Scamozzi, at Venice, the windows (decorated with a lesser order) are carried up to the height of the capitals. In the court of the Louvre the pediments of the windows come immediately beneath the architrave of the order, so that in proportion to the entire mass, and to the windows, the entablatures of the several orders become little more than deep moulded string-courses dividing the stories of the building, and the columns mere expletive decorations attached to the piers. The ornamental details may be in imitation of the members of an antient order, but the character of the antique itself is entirely gone. Even where the windows are kept more subordinate to the order itself, the effect of the latter is frequently diminished by the addition of a heavy attic pierced with windows occupying its entire length, and surmounted in turn by a balustrade, having perhaps a formal row of statues on its pedestals, which viewed at a little distance assume the appearance of so many pinnacles on the summit of the building, while the balusters themselves in such case suggest the idea of perforated battlements, in which, we may remark, they appear to have originated, since there can be little doubt that their name is derived from *Balestra*, the cross-bow, from which arrows were shot through apertures in the parapets of fortified buildings.

Notwithstanding the pedantical strictness with which rules are laid down for the different orders, they so seldom contribute anything either towards character or effect in external design, that the Italian style exhibits itself to most advantage where columns have been discarded, and windows and arches made the chief features in the composition, and the façade crowned by a bold and rich *cornicione*. Of this particular style, in which much may be effected by means of rusticated surfaces, a species of decoration well adapted to it, and admitting very great diversity in itself, we have a small yet exquisite example in the Travellers' Club House, Pall Mall, whose two fronts serve to show what variety of expression may be thus obtained. The front towards the court of the Strand portion of Somerset House is also a good sample of a purified Italian style, where an order is placed on a decorated basement.

Of late years the Italians have abandoned many of their worst architectural faults, corruptions, and caprices, and that taste for exaggerated and frittered ornament which, with here and there an exception, forms so striking a contrast to the antique. But they are still inclined to 'swear by Vitruvius,' and cherish a reverence for Palladio and Vignola. Even Cagnola (who died in 1834), one of their most distinguished architects, seems to have had very little feeling for the beauties of Greek detail as connected with the orders. In fact Greek architecture has hardly been adopted in any one instance, if we except Canova's church at Possagno, which has an octastyle portico of two ranges of columns of the antient Doric order, whose frieze is enriched with reliefs in the metopes. For an account of the modern Palladian architecture of Italy we refer to a paper on the subject in the 63rd number of the 'Quarterly Review,' which contains notices of several buildings not before described.

ITALIAN DRAMA. [ENGLISH DRAMA.]

ITALIC SCHOOL of Philosophy comprises properly two distinct schools, the Pythagorean and the Eleatic. Occasionally however it has been employed in a more restricted sense, and Italic and Pythagorean have been used as equivalent to denote the same philosophical system. The looseness and inconsistency of these different acceptations of the phrase have led to much confusion in the history of philosophy, by giving rise to a personal connection of master and teacher between philosophers who maintained respectively the opinions of Pythagoras and Xenophanes. The peculiar fitness of the designation does not easily appear, and seems to have been owing to an idle endeavour on the part of Greek literary historians to give uniformity to their divisions of the history of philosophy, which were principally drawn from an outward circumstance of a local nature, rather than any internal character of doctrine. Thus we have the Academy, the Stoics, the Megarians, the Eleatics, the Ionians, and so forth.

ITALY, one of the great natural divisions of Europe, extends from its most southern point, Capo dell' Armi, in 37° 55′ N. lat., to 46° 32′ N. lat., its most northern limit, where the Piave, the Adda, and the Ticino have their sources at the foot of the Pennine, Rhætian, and Noric Alps. It lies between 7° and 18° 30′ E. long., the latter being the longitude of the most eastern point of Italy, near Otranto. The northern part of Italy is bounded on the north, north-east, and north-west by the Alps, which sweep round it in a semicircle, beginning from the coast near Nizza, on the Mediterranean, and extending to the Adriatic in the neighbourhood of Trieste.

The ridge of the Apennines, which runs along the Riviera of Genoa, and the northern boundaries of Tuscany, to near Rimini on the Adriatic coast, divides Italy into two distinct regions. One of these regions is situated north of the Apennines, and is chiefly occupied by the basin of the Po and its numerous affluents; while its north-east extremity, which is contracted between the Carnic Alps and the Adriatic, contains the basins of the Brenta, the Piave, and the Tagliamento. The whole region extends in length, from west to east, from Mount Viso in 7° E. long. to the river Isonzo 13° 25′, a distance of 320 miles. [FRIULI.] Its greatest breadth, from the Tuscan Apennines to the sources of the Adda, is about 150 miles. [PO, BASIN OF THE.]

The other region, which is the real peninsula, extends in a south-east direction, between the Adriatic and the Mediterranean seas, for above 500 miles, its breadth varying from 130 to 50 miles, and still less in some parts of Calabria. The Apennines, and the lower ranges which are connected with them, occupy the greater part of the Italian peninsula. The tracts of level country, with the exception of the Roman Campagna and the plains of Foggia and Campania, are of inconsiderable extent, and the peninsula may be viewed as determined in its chief physical features by the long mountain range which traverses it in its whole length. [APENNINES.] The Tuscan Apennines, after running in a direction east-south-east to within a few miles of the Adriatic near Rimini, make a bend to the south-south-east, and run parallel to and near the Adriatic coast, towards which they detach numerous offsets which terminate abruptly on the sea, whilst towards the Mediterranean the slope of the ground is much more gradual, the offsets or secondary ridges running more obliquely to the coast, and forming considerable longitudinal valleys. The larger rivers of the peninsula are on the western side, and the principal basins are those of the Arno, the Tiber, the Garigliano, and the Volturno. [ABRUZZO; ARNO; CAMPAGNA DI ROMA; PAPAL STATES.] In the neighbourhood of Isernia, between the sources of the Volturno and those of the Sangro, the main ridge of the Apennines begins to run more in the centre of the peninsula, leaving to the east the vast plain of Foggia [CAPITANATA], and to the west the plains of Campania.

[Terra di Lavoro.] Farther south, near the sources of the Ofanto, two ridges detach themselves from the main group, one of which runs eastward through the Messapian peninsula, and the other westward through the peninsula of Sorrento to Capo Campanella. The central chain continues to run southward between the basin of the Sele on one side, and those of the Bradano and Basiento on the other. [Basilicata.] It then runs through Calabria, keeping however nearer to the western than to the eastern coast, but occupying with its offsets nearly the whole breadth of that part of the peninsula. [Calabria.]

Northern Italy includes the Sardinian states, Lombardy, Parma, Modena, the Venetian territories, Bologna, Ferrara, and the Romagna. Southern Italy includes Tuscany, the greater part of the Papal States, and the kingdom of Naples. With regard to climate and aspect, the narrow strip called the Riviera of Genoa, which stretches between the Apennines and the sea, may be included in Southern Italy. The islands of Sicily and Sardinia, and several minor ones near the coast, belong to Italy. A general view of the surface and geology of Italy is given in the article Apennines.

The climates of north and south Italy are very different. In the north, frosts and snow are of common occurrence in winter, and delicate plants, such as the orange and the lemon, do not thrive, except in sheltered situations; but in the south, especially near the sea-coast, tender plants thrive in the open air, and in the southernmost part of the peninsula, as well as in Sicily, even tropical plants, such as the sugar-cane, the cotton-plant, the Indian fig, and the date-palm come to maturity. The vine grows all over Italy, but the best wines are made in the south. The high Apennine regions however are bleak and cold even in the south, and as they are hardly anywhere much farther than a day's journey from the coast, there is great variety of climate in the peninsula. The staple products of Italy are corn, rice, wine, oil, silk, and fruits of every kind, and the mountains afford summer pasture for the cattle. The system of irrigation prevails in the north, especially in Piedmont and Lombardy, but the southern parts are subject to droughts in summer. The rivers which have their sources in the Alps or in the higher Apennines are perennial, whilst the other streams are mostly dry in summer. The atmosphere is remarkably clear, especially all along the coast of the Mediterranean, and the tints of the mountains and of the clouds are beautifully warm. Italy is emphatically the land of painting, of melody, and of poetry. The scenery of the Bay of Naples, of the Straits of Messina, and of the Riviera of Genoa, is unrivalled in the world.

History.—The name 'Italia' appears to have been limited in remote times to the most southern part of the peninsula as determined by a line drawn from Tarentum to Posidonia (Herodotus, i. 24; Dionysius, i. 73); and indeed its boundaries were once even more contracted. In the age of Timæus (about 264 B.C.) it stretched as far north as the Tiber, and beyond Picenum. Until the time of Augustus, Italia Proper was understood to extend only as far as the Rubicon on one side and the Macra on the other; the rest was called Cisalpine Gaul, the country of the Veneti, and Liguria.

The history of antient Italy, as a whole, is a part of the history of Rome, and the history of the several antient divisions, such as Etruria and others, requires a separate consideration. The history of those nations which preserved their independence for several centuries after the foundation of Rome, has been treated by several authors, and particularly by Micali, *Storia degli Antichi Popoli Italiani*, and sketches of it are given in this work in the articles Apulia, Campania, Etruria, &c. The reader may also refer to the 1st volume of Niebuhr's 'Roman History.' The period that elapsed after the fall of the Western Empire is noticed in the articles Belisarius, Longobards, and Theodoric.

The modern history of Italy begins properly with the reign of Charlemagne, who was crowned king of the Romans and emperor of the West in the year 800. Under the weak rule of his successors, the counts, marquises, and other great feudatories of the new Western Empire became, *de facto*, independent, and Italy was parcelled out into numerous principalities or states. As the principal towns rose in population and wealth they made themselves independent of the feudatories, and formed so many commonwealths. Then came innumerable quarrels between the towns and the great lords; of the towns among themselves; of the lords with one another; and last of all, of part of both towns and lords against the kings of Germany, who styled themselves the successors of Charlemagne, and assumed the often merely nominal title of kings of Italy and emperors of the West. (Guelphs and Guibelines.) In the midst of all this confusion some considerable states were formed, such as the Papal State, the kingdom of Sicily and Apulia under the Normans, the republics of Venice, Florence, and Genoa, and lastly the duchy of Milan. The dukes of Savoy, originally a transalpine dynasty, also acquired large possessions on the south side of the Alps. Here we have the origin of the present Italian states. A general history of modern Italy is a most intricate and unmanageable subject; sketches of the history of the various states are given in the articles Amadeus, Florence, Genoa, Sicily, Venice, &c.

At the beginning of the sixteenth century Charles V. established by conquest the dominion of the House of Austria over the duchy of Milan and over the kingdoms of Naples and Sicily, which dominion, on his abdication, he gave up to his son Philip II. and his successors of the Spanish branch of the House of Austria. Spain continued to rule these fine territories till the beginning of the eighteenth century, when, by the extinction of the Spanish branch of the House of Austria, Lombardy was transferred to the German branch of the same House, and Naples, and Sicily were formed into an independent kingdom under a Spanish infante. The duke of Savoy at the same time assumed the title of king of Sardinia. The work of amalgamation, consolidation, and national independence in Italy made great progress during the eighteenth century. Venice, Tuscany, Genoa, the Sardinian monarchy, Naples and Sicily, figured among the sovereign states of Europe, while the only part possessed by a foreign power was Lombardy. The French revolution and subsequent invasion of Italy deranged this order of things. Under the pretence of establishing republics the French exercised a military sway over Italy, whilst Venice disappeared from the list of sovereign states and became an Austrian province. Napoleon, having become emperor, formed a kingdom of Italy which however did not include one third of Italy: he annexed another third to the French empire, and gave Naples to his brother-in-law Murat. In 1814 the French evacuated Italy, and the former states were restored, with the exception of Venice, which remained under Austria. Genoa was annexed to the Sardinian monarchy, which kingdom and that of the Two Sicilies are now the two principal Italian powers: the Pope and Tuscany are the two next in importance. Several little territories and jurisdictions on the coast and the island of Elba were annexed to Tuscany, and it was also stipulated that on the demise of Maria Louisa, duchess of Parma, the duke of Lucca should succeed to her states, and Lucca should be annexed to Tuscany. Upon the whole therefore the work of amalgamation and consolidation has made further progress in the present century. The best general historians of modern Italy are Guicciardini, 'Storia d'Italia,' with the continuation by Botta till 1814; Muratori, 'Annali d'Italia,' continued by Coppi till 1820, and Bosti, 'Storia d'Italia Antica e Moderna.' Histories of particular states, towns, and periods are innumerable; the history of Florence has been written by Malispini, Dino Compagni, Villani, Poggio, Bruni, Machiavelli, Varchi, Segni, &c. Pignotti and Galluzzi have written a general history of Tuscany; that of Naples by Giannone, has been continued by Colletta to the present time: Giulini, Rosmini, and Verri have written the history of Milan; a series of writers have treated of the history of Venice, 'Istorici delle cose Veneziane,' and the historians of Genoa are equally numerous. There is hardly a town in Italy which cannot boast its native chronicler. Among the foreign historians of Italy, Sismondi deserves especial mention for the 'Histoire des Républiques Italiennes,' a work of vast research, of conscientious accuracy as to facts, and of attractive eloquence, but with a decided bias in its judgments and inferences in favour of those very unequally administered and very factious and turbulent municipal communities.

Political Divisions.—The area of Italy, with Sicily, Sardinia, and the adjacent small islands, is estimated at about 123,000 English square miles, and the population is estimated at 21 millions.

The following view is from Count Serristori's 'Saggio Statistico dell' Italia' (Vienna, 1833): the areas are taken from Neigebaur's 'Gemälde Italiens' (Vienna, 1832), but

they are to be considered only as approximations, as there is considerable discrepancy between the various authorities.

The LOMBARDO-VENETO kingdom, of which the emperor of Austria is king, consists of two great divisions: Provincie Lombarde, or government of Milan, with an area of 8460 square miles, and 2,379,000 inhabitants; and Provincie Venete, or government of Venice, with 9472 square miles, and 1,900,000 inhabitants. 2. The SARDINIAN monarchy consists of two great divisions: the Stati di Terra Ferma, or continental territories, with an area of 20,850 square miles, and 3,750,000 inhabitants, and the island of Sardinia, with an area of 8200 square miles, and 510,000 inhabitants. 3. The Grand Duchy of TUSCANY, with an area of 8700 square miles, and 1,300,000 inhabitants. 4. Duchy of LUCCA, with an area of 420 square miles, and 152,800 inhabitants. 5. Duchy of PARMA, with an area of 2300 square miles, and 454,000 inhabitants. 6. Duchy of MODENA and MASSA, with an area of 2068 square miles, and 350,000 inhabitants. 7. Republic of SAN MARINO, with an area of 27 square miles, and 7000 inhabitants. 8. PAPAL STATES, with an area of 17,860 square miles, and 2,707,000 inhabitants. 9. The kingdom of the Two SICILIES, consisting of two great divisions: Dominj di quà dal Faro, or kingdom of NAPLES, with an area of 31,610 square miles, and 5,809,000 inhabitants; and Dominj di lá dal Faro, or SICILY, with an area of 12,900 square miles, and 1,681,000 inhabitants.

The most densely inhabited state is that of Lucca, which contains 362 individuals for every square mile, and one proprietor for every four inhabitants. Next to it in population come the Lombard provinces. The most thinly inhabited parts are the Campagna of Rome and the island of Sardinia. There is no country of Europe which has so many considerable towns in proportion to its extent as Italy. Besides one city, Naples, which has above 350,000 inhabitants, there are six others, namely, Milan, Venice, Turin, Florence, Rome, and Palermo, which exceed 100,000 each; five more, namely, Genoa, Leghorn, Verona, Bologna, and Messina, have from 60,000 to 80,000; six contain between 30,000 and 40,000, namely Padua, Vicenza, Parma, Bergamo, Brescia, and Catania; seventeen contain from 20,000 to 30,000, namely, Alessandria, Asti, Cremona, Pavia, Mantua, Piacenza, Modena, Lucca, Pisa, Siena, Ancona, Perugia, Ferrara, Ravenna, Foggia, Trapani, and Cagliari; and a still greater number have a population varying from 10,000 to 20,000. The population is everywhere on the increase, at the average rate of one per cent. annually.

Of the actual social condition, manners, and temper of the Italians, we have had numerous accounts from travellers since the peace. All those which affect to give a general sketch of Italian character, even the best of them, are imperfect, and partly inaccurate; and this they necessarily must be. It is almost impossible for a foreigner to have all the requisites for such a work—the time, the preparatory information, the facilities, the introduction to the various classes of society, which would be requisite to secure a satisfactory performance of the task. Italy is not one country, inhabited by one people long fashioned and amalgamated under one central government, and receiving its form and pressure from the influence of one capital. There are not only many provincial differences, as in France and other compact states, but national differences of character, different institutions and customs, and even different languages. The steady plodding inhabitants of the broad, level, and rich plain of the Po are a very different sort of people from the active, frugal, money-seeking, adventurous, and free-spirited Genoese, or the caustic, refined, but somewhat consequential and verbose Tuscans; while the Tuscan himself is different from the mercurial, fantastical, careless and pleasure-seeking, but quick and acute Neapolitan. Again, Italian domestic society is not of easy access to foreigners; the Italians are more reserved than the French, and there is also a remarkable difference between the manners of the various classes, and between the inhabitants of the towns and the country people. It may be affirmed however of the Italians that they are possessed of great capabilities, fit for all intellectual pursuits, and for art in general; that they have a quick discernment, considerable elasticity of temper and flexibility of disposition; a natural taste for music and poetry; that they are more fond of pleasure than of assiduous labour, more inventive than persevering, naturally of warm and kind feelings, but prone to suspicion and jealousy. Morals in Italy have greatly improved within the last half century, owing chiefly to a greater diffusion of instruction, better laws, and a better system of police. Heinous crimes are become much more rare, but considerable looseness of conduct still exists in the towns; much time is lost in idle gallantry, and the conjugal bond is not sufficiently respected, especially among the middling and higher classes, though this remark admits of course of innumerable exceptions. The charge however is applicable to other southern countries besides Italy. Industry has made and is making considerable progress; better modes of agriculture have been adopted, manufactories are established everywhere, new roads and canals have been made, particularly in Lombardy, the Sardinian states, and Tuscany; and several railways are in course of being laid. The chief towns are all embellished and increasing in population. The maritime trade, especially of Genoa, Leghorn, Venice, and Naples, is thriving, though inferior to that of Trieste. And here we may observe that the trade with Italy is of greater importance to England than is commonly imagined: it appears by the official returns, that the value of British produce and manufactures exported to Italy amounts nearly to three millions sterling annually, exclusive of colonial produce, which is more than is exported to any other European country, with the exception of Germany. The annual imports from Italy into the United Kingdom are about one million and a half sterling.

Among the writers who have given the best accounts of particular parts of Italy in the present century, we may mention Rose, 'Letters from the North of Italy,' which treat of the Venetian territories; Châteauvieux's 'Lettres écrites d'Italie,' chiefly on the state of agriculture; Keppel Craven, 'Tours in Calabria and the Abruzzi;' Tournon, in his elaborate work 'Etudes statistiques sur Rome et la Partie Meridionale des Etats Romains,' which gives a faithful account of that important portion of Italy; and a very impartial article on 'Education in Tuscany in 1830,' in No. III. of the 'Quarterly Journal of Education.' Some information concerning Italian society and manners may also be derived from Millin, 'Voyages en Piémont;' Vieusseux, 'Italy and the Italians in the Nineteenth Century;' Simond, 'Voyage en Italie,' though hurriedly written and deficient in discrimination; Valery, 'Voyages littéraires en Italie;' Della Marmora and Captain Smyth 'On the Island of Sardinia;' Captain Smyth 'On the Island of Sicily;' and Benson's 'Corsica,' which last is essentially an Italian island, although belonging to France. Two critical sketches 'On modern Books of Travels in Italy' appeared in Nos. IV. and VIII. of the 'Quarterly Journal of Education;' and another on Valery's book in No. 33 of the 'Foreign Quarterly Review,' January, 1836. Accounts of the state of education in all its branches in the various Italian states are given in Nos. I., V., VI., and XVI. of the 'Quarterly Journal of Education.' Elementary or popular education is best attended to in Lombardy and Tuscany; but it is making progress also in the other states. The judicial system has also received considerable improvement. In Tuscany, Naples, and Genoa examinations of witnesses and trials are now public; while in other states the system of written depositions and trials with closed doors still prevails. Torture has been long since universally abolished. The Inquisition exists only in the Papal States.

Italian Language and Literature.—The language called Italian is the written language of Italy, and bears the same analogy to the spoken language of Tuscany and Rome as the written languages of France and England bear to the oral language spoken in the towns and provinces of those respective kingdoms in which dialects do not prevail. But while in France and England the use of dialects is confined in great measure to the peasantry of districts remote from the capitals or to mountainous parts, most of the Italian states have each a living dialect, which is the oral language of the people, and spoken even by educated people among themselves, although all educated people speak also the Italian or common written language, which they learn as a branch of education. The dialects of Italy are numerous, and most of them contain written and printed works, especially plays and other poems. The principal dialects are the following:—1. The Milanese is spoken at Milan and its territory, with some variations according to the different districts. It has been cultivated by several writers of real poetical genius, such as Maggi, Parini, and in our times

by Grossi and Porta. A selection of Milanese poems has been made, 'Collezione delle migliori Opere scritte in Dialetto Milanese,' 12 vols. 12mo. 2. The Venetian is one of the most graceful of the Italian dialects, and under the late republic was the language of the senate and of the courts of justice. There are numerous writers in this dialect; among others, Gritti, Lamberti, Goldoni, and, in our time, Buratti. A selection has been likewise made of these, 'Collezione delle migliori Opere scritte in Dialetto Veneziano,' 14 vols. 12mo. 3. The Mantuan dialect has been illustrated by the writings of the eccentric wayward monk Folengo. 4. Calvo has written in the Piedmontese, and Alfieri has given a short vocabulary of it, with the corresponding words in Tuscan. The Piedmontese has considerable affinity with the Languedocian and other Romance dialects. 5. Genoese: Foglietta and Cavalli are two of the best writers in this dialect. 6. The Bolognese is one of the most uncouth dialects of Italy, but it has some poets, among others Giulio Cesare Croce. These are the principal dialects of North Italy, besides which there are many other local ones, such as Bresciano, Bergamasco, that of Padua, which resembles the Venetian, and that of the Friuli. In South Italy the principal dialects are the following:—7. The Neapolitan, or Apulian, was the language spoken at the court of Frederic II. in the thirteenth century, and in which the history of that prince by the contemporary chronicler Matteo Spinello is written. It was afterwards spoken at the court of the Anjou and Aragonese kings of Naples, and has been in fact used within our own times by King Ferdinand and his courtiers. It is very copious, abounds with diminutives and vituperative terms, and is well suited for broad humour and for the purpose of imitative harmony. The Neapolitan among all other Italian dialects has been perhaps the most cultivated by writers. There is a collection of Neapolitan poems in 28 volumes, several of which, such as those by Cortese, Sgruttendio, Capasso, both in the humorous and the pathetic styles, have considerable poetical merit. The other South Italian dialect is, 8, the Sicilian, which can boast of Giovanni Meli, dead not many years since, who ranks among the first lyric poets of Italy, and whose works have been collected and published in seven volumes. Between the Neapolitan and Sicilian is the Calabrian dialect, which participates more of the latter, and in which there is a spirited version of Tasso's 'Gerusalemme.' Lastly, 9, the dialect of the Island of Sardinia has a great resemblance to the Catalonian and Valencian and other dialects of the Romance or Provençal language. The Sardinian is also a written dialect. There is an article 'On the Study of the Italian Language and Literature' in Nos. X. and XII. of the 'Journal of Education,' and another 'On the Dialects and Literature of Southern Italy' in No. IX. of the 'Foreign Quarterly Review' for November, 1829.

The Italian dialects must not be considered as corruptions of the written Italian, but as languages which have an affinity to and are anterior to it, and derived from the corrupt dialects of the familiar Latin or Roman which were spoken in the provinces of Italy remote from Rome, and perhaps also in part from the older languages of Italy existing previous to the Roman conquest. The influx of the northern nations effected a total corruption of the spoken Latin: articles and auxiliaries were introduced; terminations were altered or neglected; some, though not a great many, words of Teutonic origin were introduced; and various dialects resulted from these various combinations which were called by the general name of Romanc, Romanic, or Romance language, like those spoken in the south of France. The dialects spoken in Central Italy retained a greater affinity to one another, as well as to their common Latin parent. If we look at the old chronicles and other documents of the thirteenth century, written in a familiar style, whether at Naples, Rome, Bologna, or Tuscany, we see a great similarity in their syntax and etymology. The oral dialect of Tuscany seems to have attained a considerable degree of polish and grammatical regularity sooner than the others; probably it had never been so corrupt as the rest, owing to the local position of Tuscany, which was not extensively or permanently colonized by the northern tribes, and also owing to the early independence of the Tuscan cities, and their prosperity and civilization. In the rest of Italy a few men of education used also an oral language more refined than the generality of the people, which was called Lingua Aulica, or Cortigiana, and thus the early versifiers, including princes and courtiers, Frederic II. and his chancellor Pietro delle Vigne at Naples, Guido Guinicelli and Frà Guidotto at Bologna, Guido delle Colonne, a Sicilian, Can della Scala at Verona, Guido da Polenta, prince of Ravenna, wrote in a language which differs little from that of Brunetto Latini, Guitton d'Arezzo, Guido Cavalcanti, and other Tuscan poets of the same age. But Tuscany had this advantage over the rest, that its familiar spoken language was more generally polished, so as to resemble the poetical and select language of the other Italians, and the Tuscan poets had the benefit of writing in a living dialect, 'lingua volgare,' and their poems were understood by the generality of their countrymen. The writers of the fourteenth century, Dante, Dino Compagni, Petrarch, Boccaccio, Cino da Pistoja, Sacchetti, Villani, Pandolfini, were all Tuscans, and they permanently impressed on the written language of Italy the stamp of Tuscan spirit and idiom. As people of education in every part of Italy applied themselves to write in the 'lingua volgare,' the use of writing in Latin being gradually dropped, this 'lingua volgare,' or written Italian, began to form an essential part of education, and all those who received school instruction learned to speak it more or less correctly. It came afterwards to be adopted in many places as the language of the government, of the courts of justice, of the pulpit, and of the stage, and thus it has been styled emphatically the Italian language, because it is used as the general medium of communication, written and oral, all over the peninsula. But it is nowhere, except in Tuscany and in part of the Roman states, the language of the lower orders, the language of the nursery, of the markets, of convivial familiarity, of every-day life. Its general adoption is however strongly urged of late years by the various governments, and particularly attended to in all elementary schools.

The writers of the fourteenth century are called by the Tuscans the 'Trecentisti,' and they are considered by many as the purest models of Italian composition. In the fifteenth century there was a retrograde movement in the cultivation of the Italian language. The Latin again resumed the ascendency as a written language, and the 'lingua volgare' was left to the vulgar, or employed merely for familiar purposes. The discovery of the antient classics, the revival of the study of the Roman law, the arrival of many learned Greek refugees flying from the Ottoman conqueror, the influence of the Roman hierarchy, whose language was the Latin—all these circumstances gave a general impulse towards classical learning, and the Italian literati disdained to write except in the language of their presumed forefathers. Alberti, Bracciolini, Bruni, Filelfo, Panormita, Platina, Pontano, Valla, Ficino, and other learned men and also women of that age, wrote in Latin. But Lorenzo de' Medici at Florence, the Este at Ferrara, the Gonzaga at Mantua, countenanced Italian poetry, and Pulci, Bello, and Bojardo gave the first specimens of the Italian epic, while Poliziano and Lorenzo himself excelled in lyrics. In this same century Cennino Cennini wrote an Italian treatise upon painting, and the illustrious Leonardo da Vinci, painter, architect, and engineer, composed his precepts on the same art, which were published long after his death; 'Trattato della Pittura,' 1651.

The sixteenth century was the second æra of Italian literature. It has been styled the age of Leo X., because that pontiff, in the early part of the century, surrounded himself with some of the most learned men of his time. But the two great historians and statesmen Machiavelli and Guicciardini, the 'Divino Ariosto,' and Michelangelo Buonarroti, who was sculptor, painter, architect, and poet, are four names sufficient of themselves to adorn any age or country. The other principal writers of the sixteenth century were: the historians and biographers, Varchi, Segni, Bembo, Paruta, Davanzati, Costanzo, Vassari, Cellini; the poets, Sannazaro, Berni, Molza, Trissino, Guarini, and above all Tasso; the essayists, Castiglione, Della Casa, Speroni, and Bottero; the critics, Castelvetro and Salviati; the novelists, Bandello, Firenzuola, Grazzini; the architects, Barocci da Vignola, Palladio, and Marchi, and numerous others in almost every branch of learning. The learned Sigonio, Baronius, Panvinio, Vida, the jurists Alciati and Turamini, the mathematicians Maurolico and Cardano, and many other men of science, wrote in Latin. The authors of the sixteenth century are called by the Italians 'Cinquecentisti,' and are considered as models of Italian writing, though some critics observe in most of them a falling off from the

freshness and raciness of the great Florentine writers of the fourteenth century.

The seventeenth century, called by the Italians the age of the Scientisti, exhibited a degeneracy of taste, both in literature and the arts. The leaden yoke of Spanish viceroys, armed with all the terrors of delegated absolutism and of clerical inquisition, ignorant or careless of the very elements of government and administration, weighed heavily over the finest regions of Italy. The miseries resulting from that system have been described by Boccalini and Giannone, and again vividly retraced in our own time, by Manzoni in his 'Promessi Sposi,' and by Cantù in his 'Ragionamenti sulla Storia Lombarda del Secolo XVI.' The Italian writers, and especially the poets, adopted a turgid hyperbolical style, replete with false conceptions, and all the tinsel of rhetorical adulation. The school of Marini and of his worse disciples has become proverbial as the school of depraved taste in composition. However the same causes of mental degradation and corruption did not operate equally over all the peninsula. Tuscany, Venice, Genoa, Piedmont, retained their independence and with it their national spirit. Accordingly we meet here and there with writers distinguished by their sentiments as well as by their language, such as the celebrated Sarpi, the learned prelates Bentivoglio, Pallavicino, and Bellarmino; the historian Davila; the Jesuits Segneri and Bartoli; the poets, Guidi, Chiabrera, Filicaja, Tassoni, Rinuccini, Menzini; the painter and poet Salvator Rosa; the philologist Salvini; while Italian science can boast in the same age of Galileo, Cassini, Torricelli, Malpighi, Borelli, Marsigli, Redi, Viviani, and Guglielmini. Antonio Serra, one of the earliest, if not the earliest, writer on political economy, published in 1613 a treatise showing the various causes through which countries may become enriched; a work neglected and forgotten for ages after. The historian Noris, the learned antiquarian Bianchini, and the jurist Gravina, wrote in Latin.

In the eighteenth century Italian literature assumed a new character. The historians Maffei, Muratori, and Giannone, and the philosophic writers Vico, Stellini, and Genovesi, brought a new light into their respective departments. The spirit of investigation and deep reflexion was now busy at work. Goldoni effected a revolution in the Italian stage, and Metastasio imparted a new vigour and poetical freshness to the melodrama or opera. In the department of criticism there were Zeno, Baretti, Gozzi, Mazzuchelli, and Cesarotti; Milizia, Lanzi, and Bottari wrote eloquently on the fine arts; Martini and Tartini, on music; Verri, Carli, Galiani, Neri, on political economy; Bettinelli, Tiraboschi, and Corniani, on the history of Italian literature; Buonafede, on the history of philosophy: Beccaria, Filangieri, and Mario Pagano, on legislation; Vallisnieri and Spallanzani, on natural history; Volta and Galvani, on physics; Denina, on the history of Italy; Passeroni, Varano, and Parini wrote moral poetry; and lastly Alfieri created the Italian tragedy.

The invasion of Italy by the French in 1796 and the political revolution which followed, whilst they served to stimulate the minds of the Italians to exertion, had an unfavourable influence upon the language. French was the language of the conquerors, and it became the fashionable language of the conquered. Those Italians, and they formed an immense majority, who did not know French, intermixed French idioms with their already imperfect and dialectic Italian, and a spurious unseemly compound was thus formed which was neither French nor Italian, and which found its way into the political essays, the newspapers, the pleadings, and even the acts of government. A few writers, formed in a better school, opposed the torrent; among these are Alfieri, Monti, Foscolo, Ippolito Pindemonte, Napione, Cesari, and Giordani. The other principal writers of the present century are—the historian Botta, the best that Italy has produced since the sixteenth century; the tragedians Niccolini and Pellico; the romantic poets Grossi and Sestini; the didactic Arici; the satirist D'Elci; and above all, the novelist, philosopher, dramatist, and lyric poet Manzoni, who has given Italy the first model of an historical novel, an example followed by Professor Rosini in his 'Monaca di Monza,' and by several others. Nota has supplied the Italian stage with many good comedies. Micali has written the history of Italy before the Roman dominion; Bossi, a general history of Italy; Vacani, the military history of the Italian army employed in Spain under Napoleon; Cuoco and Colletta, the history of Naples; Pignotti, the history of Tuscany; Manno, that of the island of Sardinia; and Serra, the history of Genoa. Cicognara has given a history of sculpture; and Missirini, an interesting biography of the great sculptor Canova. Ugoni and Lucchesini have written on the Italian literature of the eighteenth century. Gioja has written largely on political economy and legislation; Romagnosi and Tamburini, on jurisprudence; Brocchi and Breislak, on geology and mineralogy.

These, who are only a few out of many, are the principal writers that Italy has yet produced in the present century. The best historians of Italian literature are Tiraboschi, continued by Lombardi to the end of the eighteenth century; Corniani, continued by Ugoni; Ginguené, continued by Salfi; and Fontanini's 'Biblioteca dell' Eloquenza Italiana,' with the notes by Zeno. Numerous writers have treated of particular branches, such as Aldeano, Quadrio, Crescimbeni; and series of Italian historians, dramatists, lyric poets, satirists, &c., have been published.

Italy, which has been for ages the nurse of the fine arts, has still, since the death of Canova, many respectable artists, but hardly a first-rate sculptor or painter. With architects and engineers she is better provided. The art of engraving is in a highly flourishing state; Morghen, Longhi, Gandolfi, Anderloni, and others, are first-rate artists, and the splendid works illustrative of the arts which appear in Italy, such as 'The Churches of Italy,' the 'Famiglie Celebri Italiane,' edited by Litta, and others, are equal to anything of the sort produced by any other country. (*Quadro della Letteratura, Scienze, ed Arti in Italia nell' anno* 1820, di Giuseppe Acerbi; *Saggio sulla Storia della Letteratura Italiana, nei primi* 25 *Anni del Secolo XIX*., 8vo., Milano, 1831; Sacchi, *Indole della Letteratura Italiana nel Secolo XIX.*)

The journals, both literary and political, of which forty years ago there hardly existed a dozen in all Italy, have increased to nearly two hundred since the last peace, embracing every branch of literature, science, and art. The statistics of every state of Italy are also published, as well as accounts of the state of education, legislation, industry, commerce, and other useful knowledge. Such is the condition of Italy at the time we are writing (1838), very different in reality from what it was at the end of the last century, or from what party exaggeration and querulousness would represent it still to be. An immense progress has been made, though many further improvements may still be wanted. In machinery, mercantile speculation, and practical political economy, Italy is certainly behind Germany and England, and perhaps France.

The religion of Italy is the Roman Catholic, with the exception of a few valleys among the Alps of Piedmont, inhabited by the Valdenses, and of the Jews, who live in most of the principal towns, and have synagogues. At Leghorn, Florence, Venice, and other mercantile places, chapels for foreign Protestants and Greeks are tolerated.

ITCH, or, as it is termed by nosologists, Scabies or Psora, is a disease of the skin, of which the most prominent symptom is a constant and intolerable itching. The eruption consists most commonly of minute vesicles filled with a clear watery fluid, and slightly elevated on small pimples; but its character is often obscured by a mixture of papulæ and pustules with the vesicles. Hence the disease has been divided into distinct species according to the predominance of each kind of eruption; but the distinction is artificial, and of no practical utility. The eruption occurs principally on the hands and wrists, and in those parts most exposed to friction, as the spaces between the fingers and the flexures of the joints. After a time it extends from these parts to the arms, legs, and trunk; but very rarely, if ever, appears on the face.

The itch is attended by no constitutional disorder, except in those severest forms in which the eruption consists chiefly of large pustules surrounded by considerable inflammation of the adjacent skin. It never appears to arise spontaneously; but, where cleanliness is not strictly observed, it is easily communicated by contact. Minute insects, of a species of Acarus, are often found in the vesicles; but as they are also often absent, the disease cannot be considered to depend entirely upon their presence.

A certain specific for the cure of the itch, which never gets well without treatment, is the local application of sulphur; all the parts on which the eruption is visible should be plentifully smeared with the *unguentum sulphuris* every

night, or every night and morning, till the cure is perfected, which will require from three days to a fortnight, according to the severity and extent of the disease. The ointment must remain on the parts after each application, and occasional warm baths ought to be used during the treatment.

I'THACA, called Thiaki by the modern Greeks, celebrated in antient poetry as the country of Ulysses, and now one of the seven Ionian Islands, is situated north-east of Cephalonia, from which it is divided by a channel between three and four miles wide. It is twelve miles long, and about four miles in its greatest breadth On the east coast of the island, facing the mainland of Acarnania, from which it is about twenty miles distant, is the deep Bay of Bathi, with a good harbour, and the little town of Bathi, with 3000 inhabitants. The country around is planted with vines, olive and orange trees. The remainder of the island is hilly and rocky, especially towards the western coast, with small but deep valleys between the hills, which have a good soil, and produce currants, wine, corn, oil, and all kinds of fruits. The red wine of Ithaca is one of the best in Greece. There is abundance of springs on the island, but wood is scarce. The whole population is 9566, and is scattered among eight or nine villages The habits and manners of the natives are like those of their neighbours of Cephalonia They belong to the Greek church, and the clergy are under the direction of a protopapa The cultivation of the soil, fishing, and some coasting trade, form the occupation of the people They export currants, oil, and wine The climate of Ithaca is healthy and mild. (Neigebaur, *Gemälde Italiens und der Ionischen Inseln*) [IONIAN ISLANDS]

ITHO'ME [MESSENIA]

ITTNERITE This mineral occurs crystallized in rhombic dodecahedrons and massive Structure compact Fracture imperfect conchoidal, passing into uneven. Hardness 5.0 to 6.0 Colour bluish or ash-grey. Lustre resinous to vitreous Specific gravity 2.3. It forms a jelly when put into acids Fuses *per se* before the blowpipe, with effervescence of sulphurous acid, into an opaque blebby glass. It yield d by analysis—

Soda	11·29
Potash	1 57
Silica	30·17
Alumina	28 40
Lime	5·24
Oxide of iron	0 62
Sulphate of lime	4 89
Common salt	1 62
Sulpuretted hydrogen and water	10 76
	94 56

ITURBIDE. [MEXICO]

IVAN [RUSSIA]

IVES, ST [CORNWALL, HUNTINGDONSHIRE.]

IVIÇA, or IBIZA, the Ebusus of the antient geographers, one of the Balearic Islands, lies forty-two miles south-west of Majorca, and is about twenty-seven miles long from north east to south-west, and about fifteen in its greatest breadth It is divided by a channel three miles wide from the island of Formentera, which lies due south of it. The south-west point of Iviça is fifty miles east by north of the Cabo Nao on the coast of Valencia on the mainland of Spain. The island is hilly and stony in many parts, but in others very fertile. It produces oil and wine, corn, fruits of every kind, has a large stock of sheep, and the sea near the coast abounds with fish. The manufacture of salt in salt-pans constitutes a great branch of industry. The mountains are covered with timber-trees The inhabitants are indolent and uninformed their mode of agriculture is slovenly They speak a dialect of the Limosin, the language of Valencia and Catalonia, which is a branch of the Romance language once spoken all over the south of Europe The island is divided into five cuartones or districts, namely,—Llano de Villa, Santa Eulalia, Balanzat, Pormañy, and De Salinas The capital, Iviça, built on a peninsula on the south-west coast of the island, is fortified, has a good harbour, and reckons about 6600 inhabitants: it has a cathedral and six other churches, two hospitals, and a public school or gymnasium (Miñano, *Diccionario Geográfico de España*)

IVORY, the name given to the substance which composes the tusks of elephants, is extensively used in the arts for making or embellishing numberless small articles in almost universal use, and which do not require to be further described. The principal supplies of elephants' teeth to this country are derived from the west coast of Africa and from Ceylon. Out of 5846 cwt. imported in 1837, we received 2246 cwt. from the former quarter, and 2297 cwt. from Ceylon. The remaining imports are from the coast of Barbary, the Cape of Good Hope, Madagascar, and Siam. The United States of America also send to this country some of the ivory which they import The total quantities imported and used respectively in each of the last ten years have been—

	Imported	Taken for Consumption
1828	5596 cwt	3531
1829	4345	3605
1830	5489	3628
1831	5267	3368
1832	2992	2533
1833	5042	3958
1834	6732	4282
1835	5204	3698
1836	6524	4584
1837	5846	3725

IVORY BLACK, or, as it is commonly called, *animal charcoal* and *bone black*, is prepared usually, as the latter appellation indicates, from bones heated in iron cylinders to dissipate the more volatile products of the animal matter which they contain, and to leave the phosphate of lime intermixed with much charcoal and some of the saline portions of the bone. Carbonate of ammonia is one of the products obtained.

Animal charcoal does not greatly differ in appearance from common charcoal, but there are points in which they greatly differ, thus animal charcoal obstinately retains some azote, while wood charcoal often contains hydrogen

Ivory, or bone black, possesses the singular property of completely destroying the colour of a great number of animal and vegetable solutions to much greater extent than common charcoal; thus an ounce of animal charcoal will in a few minutes entirely remove the colouring matter of a pint of red wine. This effect is more readily produced on hot than on cold fluids It is largely employed on account of its decolouring power in sugar refining, and the finer the powder to which it is reduced the greater is its efficacy.

It is difficult to give a satisfactory explanation of the decolorizing power of animal charcoal, but it appears that it is entirely dependent upon the carbonaceous matter, the action of which is however modified by the presence of the earthy salts, as the carbonate and phosphate of lime It further appears that the charcoal combines with the colouring matter, but only when it is in a state of fine powder

IVORY COAST [COAST, GOLD]

IVRE'A, a province of the Continental Sardinian States, stretches from the foot of the Alps, which divide it from Savoy and the Val d'Aosta, southward to the Po, and is watered in its length, which is about 20 miles, by the Dora Baltea The Orca, another affluent of the Po, having its source on Mount Iseran, one of the high Graian Alps, waters the western parts of the province of Ivrea, where it borders upon that of Turin. To the east, Ivrea is bounded by the province of Vercelli, and to the north, by that of Aosta The country consists in great part of hills, being the lowest offsets of the Alpine chain, and some fine valleys between, the southern part of it merges into the great plain of the Po The soil produces abundantly corn, good wine, hemp, and pastures on which a great number of cattle are fed. The system of irrigation by water drawn from the Dora and other streams is here in full operation Silk is also made, and the mountains produce plenty of chestnuts. This province was a marquisate in the middle ages, when Berengarius, marquis of Ivrea, became king of Italy It is called 'Il Canavese,' from the quantity of hemp ('canapa') which it produces, and the inhabitants are noticed in the 'History of Piedmont as quarrelsome and warlike. The population of the province is 118,000. The chief town is Ivrea, in a fine situation on the slope of a hill on the left bank of the Dora, across which is a Roman bridge of a single arch: it is at the entrance of the lowland of Italy for travellers coming by the St Bernard Pass. Ivrea is an old-looking town, with walls and a castle, it is a bishop's see, has six churches, besides the cathedral and several convents, a seminary for clerical students, a royal college, an hospital, and about 8000 inhabitants. There are some re-

mains of antiquity at Ivrea; among others, a fine urn with figures in relief. The cathedral is built on the ruins of a temple of the Sun. Ivrea, called antiently Eporedia, was a town of the Salassi, and afterwards was colonized by the Romans.

The other towns of the province are: Castellamonte, with 4800 inhabitants; Caluso, 5400 inh., and a college; Cuergnè, 3000 inh., and a grammar-school and copper-works; Agliè, 3000 inh., with a castle and a handsome park; S. Giorgio Canavese, 3300 inh., and a college; Locana, 5000 inh., with brass-works; Valperga, 2700 inh.; Pont, 2600 inh., in a delightful valley watered by the Orca and its affluent the Saona. In this valley are many natural curiosities, and the traces of silver and gold mines, said to have been once worked by the Romans. Copper is found in the Val d'Orca, and iron in the Val Brozzo, where there are several iron-works. There are several other small towns of above 2000 inh., such as Azeglio, Bolengo, Vische, S. Giusto, Pavone, Chiaverano, &c. (Neigebaur, *Gemälde Italiens*; *Calendario Sardo*; Saussure, *Voyages dans les Alpes*.)

IXA. [LEUCOSIANS.]

I'XALUS, a form of herbivorous Mammifers, placed, with doubt, by Mr. Ogilby under his family *Moschidæ*. That zoologist observes that the genus, founded upon the observation of a single specimen, may eventually prove to belong to a different family. He remarks that it differs little from the true Antelopes; but even supposing it to be correctly placed among the *Moschidæ*, other forms, he observes, are still wanting to fill up the chasms which evidently exist among that group. The type is *Ixalus Probaton*. (*Proc. Zool. Soc.*, part iv., p. 119.)

IXO'RA, a genus of Rubiaceous plants of the tribe Cinchonaceæ, so named, it is supposed, from the Indian god Iswara. The genus is characterized by having a small four-toothed calyx; corolla 1-petalled, funnel-shaped; tube long, with the four stamens in its mouth; ovary 2-celled, 1-seeded; style single; berry drupaceous, inferior, 2-seeded. The species are numerous, and chiefly confined to India and the Oriental Archipelago. They form shrubs or small trees, with opposite leaves, and stipules arising from a broad base, but acute at the apex. The flowers are in terminal corymbs, and are usually red, but sometimes white, and are generally highly ornamental, whence several are cultivated in our hothouses, where they require to be kept in a moist heat to thrive well. Some of the species are used medicinally, but not to any extent. Dr. Horsfield mentions *I. coccinea* as employed in Java as a stimulant, and Rheede two or three other species; but none appear to be possessed of any very active properties.

IXOS, a genus of birds established by M. Temminck, for those thrushes which have the bill shorter than usual, and embracing the greatest part of the *Brachypodinæ* and nearly the whole of the *Crateropodinæ* of Swainson. Ornithologists generally admit this genus; but Mr. Swainson is of opinion that, though it may be continued in artificial systems, it cannot be adopted in natural classification, since it includes genera long before defined, and unites under one name birds which actually belong to different families.

INDEX TO THE LETTER I.

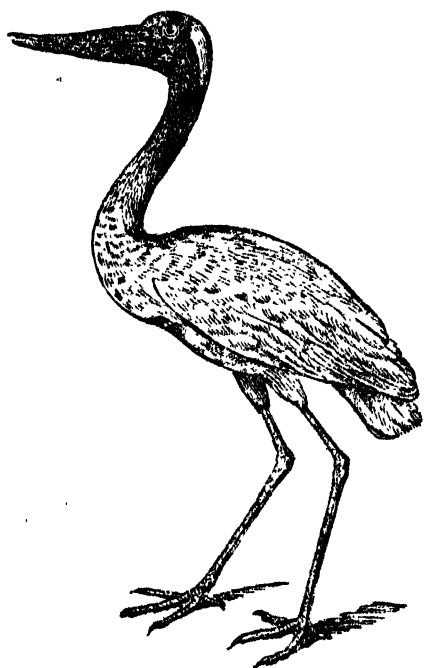
VOLUME XII.

VOLUME XIII.

J.

J, in the English language, has a sibilant sound, closely connected with that of the syllable *di* before a vowel. [ALPHABET, p. 379.] It has a similar sound in the French tongue; but in German it is pronounced altogether as our *y* before a vowel. What its pronunciation was in Latin may admit of dispute, for although it is generally laid down that its power with the Romans was the same as with the Germans, there is reason for thinking that our own sound of the letter was not unknown to the antient inhabitants of Italy. The name of Jupiter was undoubtedly written originally Diupiter, so Janus was at first Dianus, just as the goddess Diana was called by the rustics Jana. (See D and I.) The argument might be strengthened by comparing the Latin *jungo* with the Greek ζευγνυμι, Jupiter with Ζευ πατερ, &c., and also by referring to the modern Italian forms, *Giogo, giovare, giovenco, giovane*, &c. There is no absurdity in supposing that two pronunciations may have co-existed in the same country. As to the form of the letter *j*, it was originally identical with that of *i*, and the distinction between them is of recent date. Exactly in the same way, among the numerals used in medical prescriptions, it is the practice to write the last symbol for unity with a longer stroke, *vj, vij, viij*.

In the Spanish language *j* represents a guttural, and is now used instead of *x*, which had the same power: thus Jeres rather than Xeres is the name of the town which gives its title to the wine called by us sherry. For the changes to which *j* is liable, see D, G, and I.



JA'BIRU, the name of a genus of Grallatorial or Wading Birds, *Mycteria* of Linnæus, and thus characterized:—

Bill long, conical, smooth, robust, compressed, and pointed; upper mandible trigonal and straight, the lower thicker and turned up. *Head* and *neck* more or less bare of feathers. Anterior *toes* united at the base by a membrane. *Size* gigantic.

Geographical Distribution of the Genus.—South America, Western Africa, Australasia.

Habits almost entirely the same with those of the Storks.

There are three species known, distributed geographically as above. We select *Mycteria Americana* as an example.

Mycteria Americana.

Description.—Very large in size, white; the *head* and *neck* (excepting the occiput) without feathers, and covered with a black skin, which becomes reddish towards the lower part. On the occiput are a few white feathers. *Bill* and *feet* black.

Locality, South America, where it frequents the borders of lakes and marshes, preying on reptiles and fish. [HERONS, vol. xii., pp. 165, 166.]

JABLONSKI, PAUL ERNEST, the son of Daniel Ernest Jablonski, a distinguished minister of the Protestant church, was born at Berlin in 1693. He was educated at the university of Frankfort on the Oder; where he applied himself with great diligence and success to the study of the Coptic and other Oriental languages. At the age of twenty-one he was sent at the expense of the Prussian government to the various public libraries in Europe, in order to pursue his studies and to make extracts from Coptic MSS. In 1720 he was appointed minister of the Protestant church at Liebenberg; and in 1722, professor of theology at Frankfort on the Oder; and also minister of the Protestant church in the same place. He died on the 13th of September, 1757.

The most important of Jablonski's works are:—'Pantheon Ægyptiorum, sive de Diis eorum Commentarius, cum Prolegomenis de Religione et Theologia Ægyptiorum,' 3 vols. 8vo., 1750-52; 'De Memnone Græcorum et Ægyptiorum, hujusque celeberrima in Thebaïde Statua,' 4to., 1753; 'Remphah Ægyptiorum Deus ab Israëlitis in Deserto cultus,' 8vo., 1731; 'Dissertationes Academicæ de terra Gosen,' 4to., 1735, 1736; 'Disquisitio de Lingua Lycaonica' (which is mentioned in the *Acts of the Apostles*, xiv. 11), 4to, 1714, 1724; 'Exercitatio Historico Theologica de Nestorianismo,' 8vo., 1724; 'De ultimis Pauli Apostoli Laboribus a Luca prætermissis,' 4to.. 1746; 'Institutiones Historiæ Christianæ Antiquioris,' 8vo., 1754; 'Institutiones Historiæ Christianæ recentioris,' 8vo., 1756. Several of these works have been republished with many additions and corrections by Te Water, under the title of 'Opuscula quibus Lingua et Antiquitates Ægyptiorum, difficilia Librorum Sacrorum Loca, et Historiæ Ecclesiasticæ Capita illustrantur,' &c., 4 vols. 8vo., Leyden, 1804-13.

JA'CAMAR. [KINGFISHERS.]

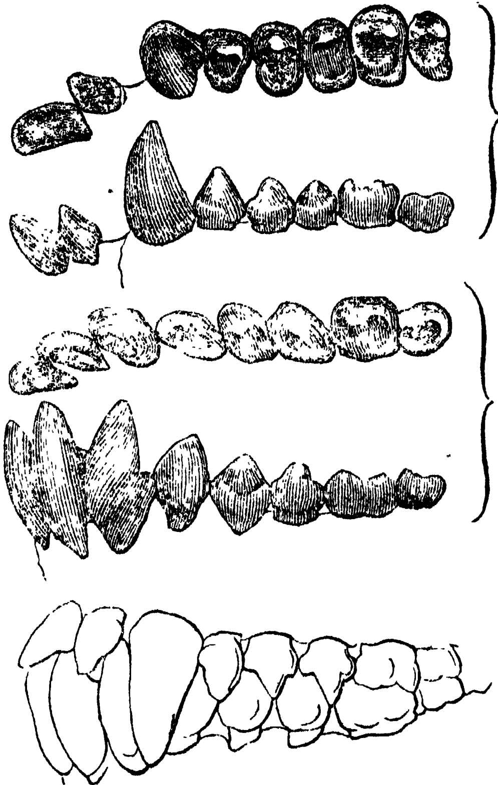
JA'CANA. [RALLIDÆ.]

JACCHUS, or IACCHUS (Mammalogy), the name of a genus of monkeys applied by Geoffroy, Desmarest, and others to the form denominated *Hapale* by Illiger, *Ouistitis* of the French, the type of which may be considered to be *Simia Jacchus* of Linnæus.

M. Geoffroy treats them as a family divided into two subgenera (*Hapale* and *Midas*), under the name of *Arctopitheci;* but the term *Arctopithecus*, it seems, had been applied by Gesner as a denomination for another animal, probably the Three-toed Sloth, whilst the latter uses *Galeopithecus* to designate the *Sagoin*.

Generic Character.—Upper intermediate incisors larger than the lateral ones, which are isolated on each side; lower incisors elongated, narrow, and vertical, the lateral ones longest; upper canine teeth conical and of moderate size; two lower ones very small.

Dental Formula: incisors $\frac{4}{4}$; canines $\frac{1-1}{1-1}$; molars $\frac{6-6}{6-6}$ $=36$.



Size small, muzzle short, facial angle about 50°. Head round, prominent at the occiput; the five fingers armed with claws, with the exception of the thumbs of the posterior extremities, which are furnished with nails; thumb of the anterior extremities in the same direction as the fingers; fur very soft; tail full and handsome.

Geographical Distribution.—South America. How Ludolph, who figures two in his 'History of Ethiopia,' could have been so far misled as to place the form in that part of the world, does not appear.

The species, which are not few, have been separated into

two sections; the first consisting of those which have an annulated tail, *Jacchus vulgaris* for instance; and the second of those whose tail is not annulated, as *Jacchus melanurus*.

We select *Jacchus vulgaris* as our example.

Teeth of Jacchus four times larger than nature. (F. Cuvier.)

Description.—This appears to be the *Simia Jacchus* of Linnæus and others; *Callithrix Jacchus* of Erxleben; *Hapale Jacchus* of Illiger and Kuhl; *Cercopithecus Jacchus* of Blumenbach; *Cagui*, *Sagouin*, *Sagoin*, *Sanglain*, and *Sanglin*, of Edwards and various authors, the latter terms being probably derived from *Sahuim*, the name by which it is said to be known near Bahia; *Ouistiti* of Buffon and the French; *Striated Monkey* of Pennant.

Length of *body* about eight inches; *tail* rather more than eleven: *colour* olive-grey, darkest on the head and shoulders, where it becomes nearly black; tail and lower part of the back barred or annulated with pale grey; lower parts of extremities brownish-grey. *Face* of a flesh colour; two tufts of pale hair spring round the ears; front *claws* hooked and thick.

Locality, Guyana and Brazil.

Habits.—The habits of the genus generally are squirrel-like, though they are, occasionally at least, carnivorous. *Jacchus vulgaris*, in a wild state, is omnivorous, feeding on fruits, roots, seeds, insects, and little birds or nestlings. The individual (in captivity) from which Edwards took his drawing fed upon biscuits, fruit, greens, insects, snails, &c., and once, when loose, it suddenly snatched a Chinese gold-fish from a basin of water and devoured it: Mrs. Kennon, to whom it belonged, after this gave it live eels, which frightened it at first by twisting round its neck, but it soon mastered and ate them. Mrs. Moore, of Rio Janeiro, sent a living specimen of *Jacchus penicillatus*, which was said to have been obtained from Bahia, to the Zoological Society of London, with the following note: 'Like most monkeys, it will eat almost anything; but its chief and favourite food, in its wild state, is the banana. It is a very delicate animal, and requires great warmth; and its very beautiful tail is in this respect eminently conducive to the comfort of the little creature, who, on all occasions when he requires warmth, rolls himself up in the natural boa with which Providence has in its wisdom endowed him.'

The *Ouistitis*, or *Sanglins*, not unfrequently breed in confinement. Edwards notices a pair that bred in Portugal, and M. F. Cuvier possessed two which had young. Three little ones were born, and the female soon ate off the head of one; but the others beginning to suck, she became careful of them and affectionate to them. The male seemed more fond of them than the mother, and assisted her in her care of them. Lady Rolle addressed a letter to the secretary of the Zoological Society of London (February, 1835), giving an account of the birth of two young ones, the produce of a pair of *Ouistitis* (*Jacchus penicillatus*, Geoff.) in her ladyship's possession. The parents were obtained in London during the preceding summer, and the young were brought forth on the 1st January. One was born dead, but the other was surviving at the date of the letter, being then about six weeks old, and appearing likely to live. It was every day put on the table at the dessert, and fed upon sweet cake. Lady Rolle stated that the mother took great care of it, exactly in the manner described by Edwards in his 'Gleanings.' It was observed that young of the same species had been born at the Society's Gardens, but not living, and that a female in the collection of the president, the Earl of Derby, at Knowsley, had produced, about the same time as Lady Rolle's, two living and healthy young ones, which were then still thriving. (*Zool. Proc.*)

Jacchus vulgaris.

Mr. Gray places the form among the Anthropomorphous *Primates* in the family *Sariguidæ*, and in its last subfamily (the 5th), *Harpalina* (Hapalina?), which is immediately preceded by *Saguinina*.

Mr. Swainson, who arranges it under his family *Cebidæ*, gives the group the appellation of *Mouse Monkeys*, because the large cutting teeth in the lower jaw strongly indicate, in his opinion, 'a representation of the order *Glires*.' [MIDAS.]

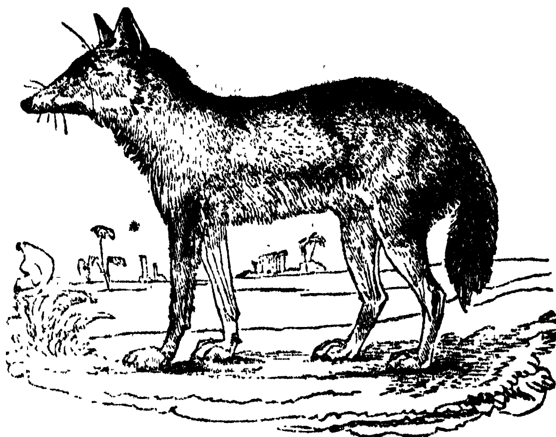
JACKAL, or TSCHAKKAL, *Chacal* or *Loup doré* of the French, *Adive* of Buffon, *Canis Aureus* of Linnæus.

Dental formula that of the Dog. Pupil of the eye round like those of the Dog and Wolf.

Description. — Yellowish-grey above, whitish below, thighs and legs yellow, ears ruddy, muzzle very pointed, tail reaching hardly to the heel (properly so called). The colours sometimes vary, and the back and sides are described by Mr. Bennett as of mixed grey and black, and as abruptly and strikingly distinguished from the deep and uniform tawny of the shoulders, haunches, and legs. The head nearly of the same mixed shade with the upper surface of the body.

Geographical Distribution.—India, other parts of Asia, and Africa. Cuvier says that Jackals are met with from India and the environs of the Caspian Sea to Guinea, but that it is not certain that they are all of the same species.

Habits gregarious, hunting in packs, and the pests of the countries where they are found, and where they burrow in the earth. In their huntings the Jackals will frequently



attack the larger quadrupeds, but the smaller animals and poultry are their most frequent prey. Their cry is very peculiar and piercing. Captain Beechey notices it as having something rather appalling when heard for the first time at night; and he remarks, that as they usually come in packs, the first shriek which is uttered is always the signal for a general chorus. 'We hardly know,' continues the Captain, 'a sound which partakes less of harmony than that which is at present in question; and indeed the sudden burst of the answering long-protracted scream, succeeding immediately to the opening note, is scarcely less impressive than the roll of the thunder-clap immediately after a flash of lightning. The effect of this music is very much increased when the first note is heard in the distance (a circumstance which often occurs), and the answering yell bursts out from several points at once, within a few yards or feet of the place where the auditors are sleeping.' These animals are said to devour the dead on the battle-field and to scratch away the earth from the shallow graves in order to feed on the corpses.

John Hunter (*Phil. Trans.*) has recorded the case of a female Jackal which whelped in this country. The period of gestation was about the same as that of the dog, and the whelps were blind at first.

The story of the Jackal being the lion's provider may have arisen from the notion that the yell of the pack gives notice to the lion that prey is on foot, or from the Jackal's being seen to feed on the remnants of the lion's quarry.

Cuvier observes that it is not certain that all the Jackals are similar ('of the same species'); those of Senegal, for example (*Canis Anthus*, F. Cuv.), he remarks, stand higher on the legs, and appear to have the muzzle sharper and the tail rather longer.

The offensive odour of the Jackal has been given as one of the reasons against reducing it to a state of domestication. We do not see what advantage is to be derived from such a process; but, if it were desirable, that objection, it seems, would not hold. Colonel Sykes, who notices it as the *Kholuh* of the Mahrattas, and as being numerous in Dukhun (Deccan), had in his possession at the same time a very large wild male and a domesticated female. The odour of the wild animal was almost unbearable; that of the domesticated Jackal was scarcely perceptible.

Jackal.

Some are of opinion that the three hundred foxes between whose tails Samson is said to have put firebrands in order that they might set fire to the crops of the Philistines (*Judges*, xv., 4, 5) were Jackals. Many of the modern Oriental names for the last-mentioned animals, *Chical* of the Turks, *Sciagal, Sciugal, Sciachal*, or *Shacal* of the Persians, come very near to the Hebrew word שׁוּעָל, *Shual*. Hasselquist, speaking of '*Canis aureus*, the Jackcall, Chical of the Turks,' says (translation), 'There are greater numbers of this species of Fox to be met with than the former (*Canis Vulpes*), particularly near Jaffa, about Gaza, and in Galilee. I leave others to determine which of these is the Fox of Samson. It was certainly one of these two animals.' This does not seem however to be quite so certain, for there are not wanting those—and Dr. Kennicott is one of them—who reject all quadrupedal aid as ancillary to the vengeance of him of Zorah. Dr. Kennicott alludes to the remark that the Hebrew word translated 'foxes' signifies also handfuls (*Ezek*. xiii. 19, 'handfuls of barley'), if the letter ו, which has been inserted or omitted elsewhere almost at pleasure, be left out. 'No less than seven Hebrew MSS. want that letter here,' says Dr. Kennicott in continuation, 'and read שׁעלים. Admitting this version, we see that Samson took three hundred handfuls (or sheaves) of corn, and one hundred and fifty firebrands; that he turned the sheaves end to end, and put a firebrand between the two ends in the midst; and then, setting the brands on fire, sent the fire into the standing corn of the Philistines.' Our limits will not allow us to dwell upon this subject, which the reader will find elaborately discussed by Dr. Harris and others.

JACKDAW, the well-known English name for *Corvus Monedula* of Linnæus.

JACKSAW, one of the provincial English names for the *Dun Diver*. [MERGANINÆ.]

JACKSON, WILLIAM, who alone is almost sufficient to refute the opinion too generally entertained, even in this country, that the English have no school of music, was born in 1730, at Exeter, of which place his father was a highly respectable tradesman. He there received a liberal education, and having evinced distinct proofs of musical genius, was placed under the tuition of the organist of the cathedral, but completed his professional studies in London, under the celebrated Travers, of the Chapel-Royal. He returned to and settled in his native city, and in 1777 was appointed sub-chanter, organist, lay-vicar, and master of the choristers of the cathedral.

Jackson first made himself known as a composer by the publication of *Twelve Songs*, which immediately spread his fame throughout the kingdom. His next work was *Six Sonatas for the Harpsichord*; but this proved unsuccessful: his power was in vocal music—in giving melodious expression to good lyric poetry, of which he always made a judicious choice, for he was too sensible a man to waste his strength in such nonsense-verses as are commonly set by the numberless pseudo-composers of the present day. His third work, *Six Elegies* for *Three Voices*, completely established his reputation; they are, and will ever continue to be, admired by all who have a cultivated, unprejudiced love of the art. This was followed by his Opera IV., consisting of twelve more songs, among which is, if we mistake not, the very lovely air, 'Go, gentle gales:' and subsequently he published two other sets of the same number of songs in each, many of which deserve to be rescued from that neglect to which fashion, that is, the rage for novelty, has condemned them. His *Twelve Canzonets for Two Voices*, all of them more or less ingenious and pleasing, were once the delight of every musical circle. Of these, 'Time has not thinned my flowing hair' has lost none of its charms; and 'Love in thine eyes for ever plays' is a duet familiarly known to most, if not all, persons of taste in the British isles. Of his three dramatic compositions *The Lord of the Manor* alone survives. The exquisitely tender air in this, 'Encompass'd in an angel's frame,' is one among the many admirable things in the opera; the words by General Burgoyne, who in a preface to the drama pays an exceedingly elegant well-deserved compliment to the composer, viewing him both as a musician and as a man.

'Originality and grace are the attributes of JACKSON *of Exeter*: there is in his works a total absence of those phrases—cant phrases they may be called—which, though fashionable and admired at the time, soon became vulgar and distasteful. He wrote not only for his own age, but for future ages. He is already admitted into the list of classical English composers, and will hereafter, when the 'venerable garb of antiquity' is thrown over him, be better known and more esteemed than at the present period; though even now all real judges of musical excellence justly appreciate his best productions. He was decried by his professional contemporaries, because superior to most of them in genius, and infinitely beyond them in education and in those attainments which become a gentleman. He was a critic too, and wrote as well as said caustic things. His mind was of large calibre; it was powerful and active; he thought for himself, and commonly thought right. His *Thirty Letters on various Subjects*, and his *Four Ages, together with Essays on various Subjects*, display the extent of his knowledge, the correctness of his judgment, and the originality of his conceptions. From those volumes music is not wholly excluded, though it occupies only a small portion of

them. But what he has written on the subject is much to the point, his criticism is just, and he has expressed his opinions in easy, appropriate language.' (*Supplement to Musical Library*.)

Jackson was no mean proficient in the sister art of painting: he chiefly employed his pencil in landscapes, making his friend Gainsborough his model; and it has been said, perhaps rather hyperbolically, that he occasionally imitated him so well, as almost to become a kind of rival. This very accomplished man died at the age of 73, leaving a widow, two sons, and a daughter. One of his sons accompanied Lord Macartney to China; his name and further history have eluded our inquiry. The other son, Francis James, filled, with great honour to himself, many diplomatic situations; he was successively secretary of legation at Berlin, minister plenipotentiary at Madrid, ambassador to the Ottoman Porte, and envoy extraordinary and minister plenipotentiary to the United States of America. He died some years ago, leaving a son and daughter.

JACKSON, PORT. [SIDNEY.]

JA'COBI, FREDERICK HENRY, a philosophical writer of Germany, was born at Düsseldorf, in 1743, and died at Munich, 10th March, 1819. He was distinguished, not so much as the author of a peculiar system of philosophy, as for the critical acumen and forcible eloquence with which he detected and exposed the incoherences and defects of the prevailing systems, of which he traced the inevitable consequences with great rigor and sagacity. Originally educated for a mercantile profession, Jacobi united the pursuits of literature to those of commerce until his appointment as councillor in the Hofkammer of his native city, which he obtained by the good offices of the Count von Golstein, enabled him to indulge his natural tastes and inclination by devoting his whole time and attention to literature. In this new career he sought to combine poetry with philosophy, and his earliest publication was a philosophical poem, entitled 'Friendship and Love,' which first appeared in 1779, but was republished two years afterwards under the simpler title of 'Woldemar.' In this year Jacobi was invited to Munich, and appointed geheimrath, in which situation he evinced the honesty and independence of his character by exposing publicly the injurious tendency and imprudence of the Bavarian system of finance. In 1781 he commenced an able controversy with Mendelsohn, by his work 'On the Doctrine of Spinosa,' which he further prosecuted in his 'Observations on Mendelsohn's Apology for the Doctrine of Spinosa.' By the essay, entitled 'David Hume, or Idealism and Realism,' he provoked the hostility of the followers of Kant, and that of the admirers of Fichte by his 'Sendschreiben an Fichte,' whose respect however, as well as that of most of his controversial opponents, he secured by the known sincerity of his character and opinions. When the troubles arising out of the French revolution extended to Germany, Jacobi retired to Holstein, whence he removed successively to Wandsbeck and Hamburg; from the latter he was called, in 1804, to Munich, to assist in the formation of the new Academy of Sciences, of which he was appointed president, in 1807. This dignity Jacobi resigned upon attaining his 70th year, but was allowed to retain the salary and emoluments. Shortly previously his work 'On Divine Things and on Revelation' (Leipz. 1811) had involved him in a bitter controversy with Schelling, who, in his answer, which bore the title 'Memorial to the Work on Divine Things,' professed to give the real position of Jacobi with respect to science and theism, or in other words, to philosophy and religion, and generally to literature. Notwithstanding the unfavourable estimate which this great philosopher drew therein of the literary and philosophical merits of Jacobi, he still maintains a high rank among sincere and honest inquirers after truth; and even if, exclusively occupied with detached speculations, he rather prepared than established a system of philosophy, the profoundness and originality of his views have furnished materials of which more systematic minds have not scrupled to avail themselves for the construction of their own theories.

As a poet, in which capacity he was greatly inferior to his brother (John George), Jacobi was a reflective rather than an imaginative thinker. His poetical merits are chiefly confined to vividness of description and to boldness of style. His philosophical writings, notwithstanding the want of all scientific method, are remarkable for the beauty of the exposition, which is conveyed in a form at once vigorous and harmonious. His views of philosophy, as far as they can be gathered from his scattered and occasional compositions on the subject, were rather of a sceptical than of a dogmatical character, and he denied the possibility of certainty in human knowledge. He maintained that all demonstrative systems must necessarily lead to fatalism, which however is irreconcileable with man's consciousness of the freedom of his rational nature. The general system of nature indeed, and man himself, so far as he is a part of that system, is pure mechanism; but in man there is unquestionably an energy which transcends and is superior to sense, or that faculty which is bound up with and regulated by the laws of nature. This higher energy is liberty, or reason, and consequently sense and reason distinguish to man two distinct spheres of his activity—the sensible or visible world, and the invisible or intelligible. The existence of these worlds no more admits of demonstrative proof than that of sense and reason themselves. Now sense and reason are the supreme and ultimate principles of all intellectual operations, and as such legitimate them, while they themselves do not receive their legitimization from aught else; and the existence of sense and reason necessarily implies the existence of sensible and intelligible objects about which they are conversant. But this existing system of things cannot have originally proceeded either from nature or from man's intellect or reason, for both nature and the human mind are finite and conditionate, and there must be something infinite and unconditionate, superior to and independent both of nature and man, to be the source and principle of all things. This being is God. Now as man's liberty consists in his personality or absolute individuality, for this constitutes his proper essence, while the mechanism of nature is hereby distinguished from man, that none of its members are individual of character, therefore that which is superior both to nature and to man must be perfectly and supremely individual; God consequently is one only, and strictly personal. Moreover, as the ground of all subsistence, he cannot be without subsistence; and as the principle of reason, he cannot be irrational. Of the existence of this divine intelligence however all direct proof is as impossible as a demonstration of existence simply. Generally indeed nothing can be known except upon testimony, and whatever rests on testimony is not certainty but *faith*, and such a faith or belief, when its object is the existence of a good and supreme being, is religion.

Jacobi's complete works have been published in 6 vols., Leipz. 1819-20.

JACOBINS is the name of a faction which exercised a great influence on the events of the French Revolution. This faction originated in a political club formed at Versailles, about the time of the meeting of the first National Assembly, and which was composed chiefly of deputies from Britanny, who were most determined against the court and the old monarchy, and some also from the South of France, among whom was Mirabeau. When the National Assembly removed its sittings to Paris (October 19, 1789), the Breton club followed it, and soon after established their meetings in the lately suppressed convent of the Jacobins, or Dominican monks, in the Rue St. Honoré. From this circumstance the club and the powerful party which grew from it assumed the name of Jacobins. During the year 1790 the club increased its numbers by admitting many men known for violent principles, which tended not to the establishment of a constitutional throne, but to the subversion of the monarchy. A schism broke out between these and the original Jacobins, upon which Danton, Marat, and other revolutionists seceded from the club, and formed themselves into a separate club called 'Les Cordeliers,' from their meetings being held in a suppressed convent of Franciscan friars. [DANTON.] These men openly advocated massacre, proscription, and confiscation, as the means of establishing the sovereignty of the people. In 1791 the Cordeliers reunited themselves with the Jacobin club, from which they expelled the less fanatical members, such as Louis Stanislas Freron, Legendre, and others. From that time, and especially in the following year, 1792, the Jacobin club assumed the ascendency over the legislature; the measures previously discussed and carried in the club being forced upon the assembly by the votes of the numerous Jacobin members, and by the out-door influence of the pikemen of the suburbs, with whom the club was in close connexion. The attack on the Tuileries in August, 1792, the massacres of the following September, the suppression of royalty, and most of

the measures of the reign of terror, originated with the club of the Jacobins. [COMMITTEE OF PUBLIC SAFETY.] The club had affiliations all over France. After the fall of Robespierre in July, 1794, the convention passed a resolution forbidding all popular assemblies from interfering with the deliberations of the legislature. The Jacobins however having attempted an insurrection in November, 1794, in order to save one of their members, Carrier, who had been condemned to death for his atrocities at Nantes, the convention ordered the club to be shut up; and Legendre, one of its former members, proceeded with an armed force to dissolve the meeting, and closed the hall. The spirit of the club however survived in its numerous adherents, and continued to struggle against the legislature and the Executive Directory, until Bonaparte put an end to all factions, and restored order in France. The name of Jacobin has since continued to be used, though often improperly applied, like other party names, to denote men of extreme democratical principles, who wish for the subversion of monarchy and of all social distinctions, and are not over-scrupulous about the means of effecting their object.

JACOBITES. [EUTYCHIANS.]

JADE, a name which has been given to several minerals which resemble each other but little, except in colour, and therefore it is one which it would be well should fall into disuse.

Serpentine, nephrite, and Saussurite have all been described under the name of jade. Yu, or Chinese jade, is supposed to be prehnite.

JAEN, an intendencia, or administrative province, of Spain, once a Moorish kingdom, is included in the geographical division of the Peninsula called ANDALUSIA. The province of Jaen consists in great measure of the upper basin of the Guadalquivir, and of the numerous streams which contribute to the formation of that river, and it lies between the Sierra Morena on the north, which divides it from Castile, the great southern range or Sierra Nevada on the south towards Granada, and the Sierra de Cazorla on the east, which forms the connecting link between the other two, on the borders of Murcia. To the west the ground slopes with the course of the Guadalquivir towards Cordova. Numerous offsets of the above chains enter and cross the territory of Jaen; such are the Sierra de Bedmar, Sierra de Ubeda, &c. The province of Jaen is 75 miles from east to west, and nearly as much from north to south, and its area is estimated at about 4000 square miles, with a population of 277,000 inhabitants, distributed among 71 pueblos or communes. The province is divided into five partidos or districts, Jaen, Andujar, Baeza, Martos, and Ubeda. The soil in the valleys is extremely fertile, but very imperfectly cultivated. The produce is wine, oil, corn, vegetables and fruits of every kind; honey and silk are also gathered. The mountains abound with rich pastures; sheep and a fine breed of horses are the principal cattle in the country. Jaen, the capital of the province, is a bishop's see, with a fine cathedral, and has 19,000 inhabitants. At Cazalla, south of Jaen, are mines of lead and silver, and veins of copper are found in various parts of the province. In the northern part, at the foot of the Sierra Morena, is the German colony of La Carolina, founded by the philanthropist Olavides, in 1767. (Miñano; Bowles; Ponz; Bourgoing.)

JAEN. [ECUADOR, vol. ix., p. 267.]

JÆRA, or JAËRA. [ISOPODA, vol. xiii., p. 55.]

JAFFA. [SYRIA.]

JAFFNAPATAM, the principal town of the province of Jaffna in the island of Ceylon, is situated in 9° 47′ N. lat. and 80° 9′ E. long.; 215 miles north from Colombo, and 296 south-west from Madras. It possesses a large fort built in the form of a pentagon, with five bastions, furnished with a broad moat and an extensive glacis; and having within its walls a church in the form of a Greek cross, a commandant's house, and some other good buildings, besides barracks and accommodations for soldiers. The town stands to the eastward at the distance of half a mile, and contains several broad parallel streets intersected by smaller ones. The houses are for the most part built with brick. The majority of the inhabitants of the town formerly consisted of the Dutch and their descendants, but since the British conquest many have emigrated to different parts of the island, and some have gone to Batavia. The bazaar is abundantly supplied with the necessaries of life at a cheap rate. In the neighbourhood there is a church belonging to the Tamul Protestants, called St. John's, in which the Tamul colonial chaplain of the district officiates. The Hindus have a large temple in the neighbouring town of Wannapanny, which far exceeds in grandeur all the rest in the province. It is ornamented with an accumulation of small towers, and enclosed by a wall having a large gateway. It was founded and endowed by one Wyti Linga Chetty, about forty years ago. There is a band of dancing girls attached to the temple, who enliven the processions with their dancing.

Jaffnapatam is not accessible to vessels of any considerable size, owing to the shallowness of the water. The cargoes of the larger vessels are unloaded at Kails, and conveyed up to the town in small boats.

Jaffnapatam is the seat of a government agent, who is deputy fiscal, and of a provincial judge, who are gentlemen of the civil service. They form a minor court, to decide on appeals from the courts of the subordinate magistrates of the province of Jaffna.

JAGANATH. [JUGGERNAUTH.]

JAGER. (Ornithology.) [LARIDÆ.]

JAGUAR. [LEOPARDS.]

JAINAS, a religious sect of the Hindus. The name is derived from the Sanskrit *jina*, 'victorious,' which is the generic name of the deified saints of this sect.

The Jainas are very numerous in the southern and western provinces of Hindustan; they are principally engaged in commerce, and from their wealth and influence form a very important division of the population of the country. The history and opinions of this sect are also interesting from their striking similarity to the chief peculiarities of the religion of Buddha. The earliest information concerning this sect was given in the 9th vol. of the 'Asiatic Researches,' in an 'Account of the Jains, collected from a priest of this sect, at Mudgeri, translated for Major Mackenzie;' in 'Particulars of the Jains,' by Dr Buchanan; and in 'Observations on the sect of Jains,' by Colebrooke. Several particulars concerning them are also given in Buchanan's 'Journey from Madras through Mysore,' &c.; Wilks's 'Historical Sketch of the South of India;' in the work of the Abbé du Bois; and in Ward's 'View of the History, Literature, and Religion of the Hindus.' Information still more important is given in the 1st volume of the 'Transactions of the Royal Asiatic Society,' by Colebrooke, 'On the Philosophy of the Hindus;' by Major Delamain, 'On the Srâwaks, or Jains;' by Colebrooke, Dr. Hamilton, and Col. Franklin, 'On Inscriptions in Jain Temples in Behar;' by Dr. Hamilton, 'On the Srâwaks, or Jains;' and also in the 2nd volume of the Transactions, by Major Todd, 'On the Religious Establishments in Mewar.' But the most complete account of this sect is given by Prof. Wilson, in his 'Sketch of the Religious Sects of the Hindus.' (*As. Res.*, vol. xvii.)

A view of the literature of the Jainas is given by Wilson in his 'Descriptive Catalogue of the MSS., &c., of Col. Mackenzie,' vol. ii., pp. 144-162. The Jainas have their own Purânas and other religious works, which are principally devoted to the history of the Tôrthankaras, or deified teachers of the sect. The chief Purânas are supposed to have been written by Jina Sena Achârya, who was probably the spiritual preceptor of Amoghaversha, king of Kânchî, at the end of the ninth century of the Christian æra. They have also their own works on astronomy, astrology, medicine, the mathematical sciences, and the form and disposition of the universe, of which a list is given in Wilson's 'Descriptive Catalogue.' 'But the list there given is very far from including the whole of Jain literature, or even a considerable proportion. The books there alluded to are in fact confined to Southern India, and are written in Sanskrit or the dialects of the peninsula; but every province of Hindustan can produce Jain compositions, either in Sanskrit or its vernacular idiom; whilst many of the books, and especially those that may be regarded as their Scriptural authorities, are written in the Prakrit or Magadhi, a dialect which, with the Jains as well as the Bauddhas, is considered to be the appropriate vehicle of their sacred literature.' (Wilson, *As. Res.*, vol. xvii., p. 242-3.) The Jainas are also said to have a number of works entitled Siddhântas and Agamas, which are to them what the Vedas are to the Brahmanical Hindus.

The Jainas are considered by the Brahmans to form no part of the Hindu church. The principal points of difference between them and the Brahmanical Hindus are:—

1st, a denial of the divine origin of the Vedas; 2dly, the worship of certain holy mortals who have acquired by self-mortification and penance a power which renders them superior to the gods; and 3dly, extreme tenderness for animal life. These doctrines and customs are essentially the same as those of the Buddhists. The Jainas do not entirely reject the gods of the Hindu mythology; but they consider them greatly inferior to the Jinas, who are the objects of their religious adoration. The Jainas enumerate 72 mortals who have raised themselves to the rank of Jinas by their virtue and self-mortification; of whom 24 belong to the former age, 24 to the present, and 24 to the age to come. The statues of all or part of these are in all their temples, sculptured in black or white marble. They are distinguished from each other in colour and stature: two are represented as red, two as white, two as blue, two as black, and the rest as of a golden hue or yellowish-brown. Of these Jinas the most celebrated are Pârsvanâtha and Mahâvira, who alone can be regarded as having any historical existence. The last Jina is said, according to some accounts, to have died at the age of seventy-two, about B.C. 500; but, according to others, about B.C. 663, two hundred and fifty years after the preceding Jina Pârsvanâtha: but these dates, in common with most others in early Hindu history, are very uncertain.

The origin of this sect has been a subject of much dispute. Some have endeavoured to prove that Buddhism and Jinism are more antient than the Brahmanical religion; but several arguments have already been brought forward in another part of this work which render this hypothesis exceedingly improbable. [BUDDHA, vol. v., p. 526-7.] It has, on the contrary, been maintained with greater probability, from the absence of all allusion to Jinism in the antient Brahmanical and Buddhistic works, and from the comparatively late date of all inscriptions and monuments relating to the Jainas which have yet been discovered, none being earlier than the ninth century, that the sect of the Jainas did not become of any importance till the eighth or ninth century of the Christian æra. The striking similarity between the Buddhists and Jainas renders it probable that they had the same origin; and that Jinism is merely another form of Buddhism, accommodated to the prejudices of the Brahmanical Hindus. In the southern provinces of Hindustan, where the Jainas are the most numerous, the distinction of castes is preserved among this sect; but it appears probable, from many circumstances, that originally they had no distinction of caste; and even in the present day in the upper provinces, the Jainas all profess to be of one caste, namely, the Vaisyas, which is equivalent to their being of no caste at all. The Jainas also allow Brahmans to officiate as the priests of their temples. The period in which we have supposed Jinism to have first risen into importance corresponds with the time in which the Buddhists were finally expelled from Hindustan. (Wilson's *Sanskrit Dictionary*, 1st edit., preface, pp. xv.-xx.) It therefore appears probable that those Buddhists who were allowed to remain adopted the opinions and practices of Jinism, which may previously have existed as an insignificant division of the Buddhistic faith. In the eleventh and twelfth centuries the religion of the Jainas appears to have been more widely diffused than at any other period. Many princes in the southern part of the peninsula embraced this faith; but it gradually lost much of its power and influence, in consequence of the rapid progress of the Vaishnavas and Saivas. [HINDUSTAN, vol. xii., p. 233.]

The Jainas were antiently called Arhatas, and are divided into two sects, of which the former is called Vivasanas, Muktavasanas, Mucktâmbaras, or Digambaras, in reference to the nakedness of this order; and the latter Swetâmbaras, 'clad in white,' because the teachers of this sect wear white garments. The former are the more antient. In the early philosophical writings of the Hindus, in which the Jainas are mentioned, they are almost always called Digambaras, or Nagnas, 'naked.' The term Jaina rarely occurs, and that of Swetâmbara still more rarely. These two sects, though differing from each other in very few points, oppose one another with the bitterest animosity. A few years ago the British government at Benares was obliged to call in the military to put down a riot in the city, which had been produced by the quarrels of these sects.

The Jainas are also divided into Yatis and Srâvakas, clerical and lay; the former of whom subsist upon the alms of the latter. The religious ritual of the Jainas is very simple. The Yatis dispense with acts of devotion at their pleasure; and the Srâvakas are only bound to visit a temple daily, where some of the images of the Jinas are erected, and make a trifling offering of fruit and flowers, accompanied by a short prayer. The Jaina temples are generally superior in size and beauty to those which belong to the Brahmanical religion. Bishop Heber (*Journal*, i., p. 292) has given us an account of his visit to one of these temples, from which strangers are usually excluded with jealous precautions. 'The priest led us,' he says, 'into a succession of six small rooms, with an altar at the end of each, not unlike those in Roman Catholic chapels, with a little niche on one side, resembling what in such churches they call the *piscina*. In the centre of each room was a large tray with rice and ghee strongly perfumed, apparently as an offering, and men seated on their heels on the floor, with their hands folded as in prayer or religious contemplation. Over each of the altars was an altar-piece, a large bas-relief in marble, containing, the first five, the last in succession twenty-five figures, all of men sitting cross-legged, one considerably larger than the rest, and represented as a negro. He, the priest said, was their god; the rest were the different bodies he had assumed at different epochs, when he had become incarnate to instruct mankind. The doctrines he had delivered on these occasions make up their theology, and the progress which any one has made in these mysteries entitles him to worship in one or more of the successive apartments which were shown us.'

The moral code of the Jainas is expressed in five *Mahâvratas*, or 'great duties:' 1st, refraining from injury to life; 2nd, truth; 3rd, honesty; 4th, chastity; 5th, freedom from worldly desires. There are also four *Dhermas*, or 'merits:' liberality, gentleness, piety, and penance.

JALAP. [CONVOLVULUS JALAPA.]

JALAPA. [MEXICO.]

JALISCO. [MEXICO.]

JALLOFFS, or YALLOFFS, are a negro tribe who occupy a considerable tract of country between the rivers Senegal and Gambia. They are considered as the finest race of negroes in this part of Africa; they are tall and well made, their features are regular, and their physiognomy open. Though bordering on the Foolahs and Mandingos they differ from both, not only in language, but in features. The noses of the Jalloffs are not so much depressed nor the lips so protuberant as among the generality of Africans, but their skin is of the deepest black. They are chiefly employed in agriculture, and have made some progress in the useful arts, especially in the manufacture of cotton cloth, which they make better than any of the neighbouring tribes. Though Mohammedans they have not adopted the system of the Arabic numbers, but count only up to five, so that six is expressed among them by five and one, seven by five and two, and so on. They are divided into several independent states, or kingdoms, which are frequently at war either with their neighbours or with each other. (Mungo Park's *First Travels into the Interior of Africa*; Golberry's *Fragments*.)

JAMAICA, one of the Greater Antilles, and the most important possession of the British in the West Indies, extends from 76° 15′ to 78° 25′ W. long., and from 17° 40′ to 18° 30′ N. lat. Its length from east to west is nearly 150 miles, and its width may on an average be 40 miles. It contains, according to Mr. Robertson's survey, 2,724,262 acres, or 4256 square miles, and is much less in extent than the county of York. Only 1,100,000 acres are stated to be under cultivation.

The surface of this island is very uneven, and the tracts which are level probably occupy less than one-twentieth of its area, but it is only the eastern part that can properly be called mountainous. This part is almost entirely filled up by the Blue Mountains, whose principal ridge occupies the middle of it, and runs nearly east and west. This range varies from 5000 to 6000 feet in elevation; its summit is in some places so narrow as not to be more than three or four yards across. Its numerous offsets run south and south-east, or north and north-west. On one of the latter offsets rise three peaks, of which the most northern and the highest attains an elevation of 7150 feet above the sea. The western boundary of this mountain-region is formed by a ridge, running across the whole island from south-east to north-west. This ridge begins on the south at Yallah Point, and terminates to the north-east of the mouth of the Agua Alta, or Wagwater river. It rises to a considerable height, frequently to 2500 and 3000 feet; and S. Catherine's Peak,

at the point where it is united to the range of the Blue Mountains, is 4500 feet above the sea-level. The declivities of the mountains are rather steep, partly bare, and partly covered with woods, but the level summits are generally overgrown with trees. The valleys are mostly narrow, and contain but little level ground, with the exception of the vale of Bath, which extends about eight miles from the town of that name to the mouth of the Plantain Garden river, near the promontory of Morant Point, the most eastern cape of the island. This vale is about one mile and a half wide, and covered with sugar plantations.

West of the range in which S. Catherine's Peak stands the mountains subside, and are divided from those farther west by a depression which extends across the island over the plain of Liguanea and the hilly country which encloses the banks of the Wagwater river. Yet north of the plain the country seems to be 1000 feet above the sea-level, or nearly so. The greatest plain in the island is that of Liguanea, which begins a few miles east of Kingston, and extends westward to a point west of Old Harbour, a distance of about thirty miles: its average breadth is about five miles. The western portion of this plain has a considerable inclination. It is defended from the sea by the Palisados, a sand-bank several miles in length, which joins the town of Port Royal to the mainland of the island. A part of this plain consists of savannahs, or natural pasture-ground, covered with grass. West of Port Henderson a range of low hills called Healthshire Hills lie betwen the plain and the sea.

The plain of Liguanea is divided from the plain of Vere by a narrow range of low hills, which approach the sea west of Old Harbour, near Salt River Bay. The plain of Vere extends from south-east to north-west about 18 miles, with an average breadth of 7 or 8 miles. On the south-east of this plain is the Portland Ridge, which terminates in Portland Point, the most southern cape of Jamaica. On the north-west it is joined by the Mile Gully, a picturesque valley, several miles in length, traversed by the upper course of the Minho river. The soil of the plain of Vere is of moderate fertility, and mostly used as pasture-ground.

The mountains which enclose these plains on the north rise with a steep and abrupt ascent, but they do not attain a great elevation, hardly any summit being 3000 feet high, and most of them not 2000 feet. These mountains do not occupy the whole of the country, but enclose valleys of considerable extent and fertility, and the basin of St. Thomas-in-the-Vale, a plain embosomed in hills, about 9 miles long and 2½ miles across, which is covered with sugar plantations, and is very fertile. Towards the northern coast the mountains sink down into low and well-wooded hills.

The mountains, which cover nearly the whole of the island west of the basin of St. Thomas-in-the-Vale, do not rise much higher than those which enclose the basin. Their mean elevation falls short of 2000 feet, and few of their summits attain more than that elevation. The highest seems to be the Peak near Blewfields, not far from the southern coast, which rises to 2560 feet. Properly speaking, the ridges do not extend in one general line, but intersect each other in various direction, so as to form valleys, which open to nearly every point of the compass. Near the central line of the island, the hills present the characteristics of the limestone formation, of which they consist. Caverns occur in several places, and some of them are very extensive. In the midst of the hills are also cavities and depressions, sometimes of considerable extent. The water which runs down from the hills or falls into these cavities during the rains forms small rivers, which flow for a short distance and then disappear in sink-holes, and sometimes come again to the surface and again sink. These districts are only provided with running water during the rains, and the inhabitants are obliged to have recourse to tanks or cisterns, in which they collect the rain-water for the dry seasons. In the western part of the island the level grounds are not of great extent. The largest plains are the Pedro Plains, near Great Pedro Point, and the Savanna la Mar, towards South Negril Point, the most western cape of the island. A considerable portion of these plains is low and covered with swamps. No plains occur on the northern coast. The country between Montego Bay on the west and St. Ann's Bay on the east consists only of low though abrupt and precipitous hills; the valleys between them are covered with high forest-trees, which exhibit a very luxuriant vegetation.

Except the districts which lie within the limestone formation above mentioned, Jamaica has the advantage of being well watered by numerous rivers, rivulets, and springs. None of the rivers are navigable, except the Black River, in the parish of St. Elizabeth, by which goods are brought down and carried up about 30 miles in flat-bottomed boats and canoes. But the other rivers are of great importance for the water which they supply for the irrigation of the plantations, the numerous mills which they turn, and the beauty and interest that they give to the country through which they flow. Some of them form beautiful cascades.

The want of river navigation can hardly be felt in an island like Jamaica, which has a coast-line of more than 500 miles, in which hardly any place is more than 30 miles from the sea, and whose shores are sufficiently indented to supply it with numerous harbours and other shelters for shipping. There are 30 principal harbours, besides more than double that number of bays, creeks, and coves, capable of affording more or less shelter to vessels. The safest and most capacious of the harbours are those of Port Morant, Kingston, and Old Harbour on the southern, and those of Lucia and St. Antonio on the northern shores.

The climate of Jamaica is considered exceedingly hot, but this is only the case in the lower plains along the southern coast. The mean heat of the summer months (from June to November) is about 80°, whilst the mean heat of the other six months does not exceed 75°. In summer the thermometer sometimes rises to 96°, and occasionally, though rarely, to 100°. In winter it sinks to 69°. But the changes of the temperature are very slow and gradual, the difference between noon and midnight rarely exceeding 5° or 6°. The mean heat on the hills, which are 1000 feet and upwards above the sea, in summer is stated to be 75°, and in winter between 70° and 72°, though the thermometer occasionally sinks to 55°, and on the higher mountains even to 48°. Snow has never been observed, even on the most elevated peaks; hail is not a rare occurrence on them, but it melts as soon as it reaches the ground. The climate is cooler and more salubrious on the north side of the island than on the south. The heat of the low coast is considerably diminished by the daily sea-breeze, which sets in generally about nine o'clock in the morning and ceases only towards sunset. Its salubrious effects are so obvious, that it has obtained from the seamen the name of the *doctor*. During the hottest part of the day, and in the most sultry months, a succession of light flying clouds continually pass over the sun, and, by interrupting its rays, contribute to moderate the heat.

In Jamaica there are two rainy and two dry seasons. The spring rains begin some time after the sun has passed the equator, in the middle of April or beginning of May. But in these months the rains are generally partial, and come down only in showers: the dry weather frequently continues to the month of June, especially on the southern side of the island. The heavy rains commence in June or even later, and last about two months; they are by far the most violent of all that occur during the year, and at this time the air is most intolerably sultry. This intense heat, joined to a still breathless atmosphere, is a presage of the approaching torrents. The clouds hastily gather, and form into a compact mass, overspreading the sky, which just before was cloudless and serene. A tremendous peal of thunder bursts from these dark clouds, and in a few minutes the rain descends in torrents, of which no one can form an idea who has not witnessed them. During the continuance of the rain the heavens are rent with incessant peals of thunder and quick and vivid flashes of lightning. These rains set in regularly every day, and continue from two to three hours, sometimes for the space of several weeks. Sometimes very heavy rain descends for several days and nights with little intermission. The autumnal or *fall rains*, as they are called by the planters, come in October and November: they are by no means so heavy as those of the spring, nor are they usually accompanied with thunder and lightning, but they are often attended with heavy gusts of wind from the north. In the mountains the rains are earlier, more frequent, and more heavy than in the low country.

Jamaica is from time to time visited by those terrific phenomena called hurricanes. They generally set in from the north or north-west, but only in the summer months between the two rainy seasons, which months are therefore called

the hurricane months in the West Indies. They are usually succeeded by long droughts, by which those crops which are spared by the tempest are arrested in their growth, and a famine is the consequence. But hurricanes occur less frequently in Jamaica than in the Lesser Antilles.

The low tracts along the coast are unhealthy, but the hilly and mountainous country is much less so. The most common diseases are the yellow fever, common bilious fever, and the typhus fever; the first is by far the most destructive, especially to new comers, who are not yet inured to the climate.

The staple articles of the island occupy the greatest portion of the time and industry of the agriculturist, but he does not neglect the cultivation of several kinds of grain, of ground provisions, and even of grasses for the numerous herds of cattle which are kept. Sugar, rum, and molasses form by far the most important articles of export. The sugar plantations are very numerous and extensive, especially in the lower and warmer tracts of the island. On the hills and their declivities coffee is cultivated to a great extent. Next to these the pimento plantations supply the most important article of export. Arrowroot, indigo, which formerly was much more cultivated than at present, ginger, turmeric, and cacao are also cultivated. The last-mentioned article has been gradually neglected, and at present little more is raised than is sufficient for the consumption of the inhabitants. A considerable quantity of castor-oil is produced, but the greater part is consumed in the island. Tobacco is only cultivated by the negroes for their own use, and it is inferior to that of Cuba.

No kind of European corn is raised in Jamaica. Indian corn is universally cultivated, and yields an abundant produce; two and even three crops of it can be raised within the year. Guinea-corn is not much raised on the north side of the island, but in some districts on the south the negroes chiefly subsist on this grain, which is adapted to resist the two greatest obstacles to vegetation, poverty of soil and drought. Rice could be raised on the low and marshy lands, but it is not an object of attention.

A variety of wholesome and nutritious roots cultivated in this island are called by the name of *ground provisions;* such as the yam (Dioscorea alata), cassava (Jatropha Manihot), the sweet potato (Convolvulus Batatas), and some other roots. As these roots are not liable to sustain very severe injury from the frequent storms, or the hurricanes, every plantation has several acres planted with such provisions, over and above the negro-grounds and the plantain-walks.

A few kinds of grass are cultivated for cattle. The most important is the Guinea-grass, a hardy plant, which covers the rugged and stony portions of land, and yields three and sometimes four cuttings, or as many grazings, in the year. The Scotch grass grows with great luxuriance by the sides of the rivers and other moist situations; but it cannot be cultivated to a great extent.

None of the European fruits arrive at perfection except grapes. Apples are of very inferior quality and peaches rarely produce fruit. No other kinds succeed in any degree except a few tolerable strawberries. But there is a great abundance and variety of other delicious fruits, as the pine-apple, the orange, the shaddock, the pomegranate, the fig, the granadilla, the sapodilla, the star-apple, the sweet-sop, the sweet-lemon, the citron, the avocado-pear &c. Several exotics have been introduced within the last sixty years, as the mango, the cherimoyer, the bread-fruit, &c. But the most important is the plantain, or banana, which is extensively cultivated on every plantation.

The forests of Jamaica abound with a great variety of the most valuable woods. Some of them, which are susceptible of the highest polish, are too hard to be used in cabinet-work. The most beautiful woods for such work are the mahogany, the bread-nut hearts, and the satin-wood. The Jamaica mahogany is superior to that of Cuba or Belize, but there are not many mahogany-trees now remaining. The bread-nut tree is still abundant in most parts. The cedar-tree attains a great size, but it is not of so fine a grain as that of the Levant. Other trees produce dye-woods, as the fustic, the logwood, &c. The cotton-tree is the largest of all, but is only used for making canoes, which are hollowed out from the trunks; its cotton is employed for stuffing beds. The bamboo grows wild, and is also cultivated. The cabbage-palm (areca oleracea) and the cocoa-nut-tree are the most useful trees of the palm tribe. Notwithstanding this abundance of useful trees, white oak is imported for rum-puncheons, and considerable quantities of pine of all dimensions from the United States, this wood being sold at a lower price than the native timber.

The horned cattle are very numerous, oxen being employed in the waggons, which bring down the produce to the wharfs, and also in carts and in the plough. The horses are of a middle size, hardy and active, but only fitted for the saddle and harness. Mules are numerous, and employed in the sugar-mills and in conveying the sugar-canes to the works. Sheep and goats abound; many of the former have no fleece, and are covered with hair, like goats. Hogs are very plentiful: they are of a smaller size than the English hog, but their flesh is superior in delicacy to the British or American pork. All kinds of poultry are raised in the greatest abundance, excepting geese and the common duck. But the muscovy-duck, the turkey, the guinea-fowl, and the common-fowl thrive very well. Domestic pigeons likewise abound. Rats exist in incredible numbers, and destroy about one-twentieth part of the sugar-canes throughout the island. Fish abound in the sea and rivers. The alligator appears in some of the largest of the rivers, but does not attack men.

No metal but lead is known to exist. There are some salt-springs.

Jamaica is politically divided into three counties, Surrey, Middlesex, and Cornwall, and contains one city, Kingston, and thirty-three towns and villages. The counties are subdivided into 21 parishes.

1. The county of Surrey extends over the eastern portion of the island, comprehending the whole of the region of the Blue Mountains and the eastern portion of the Plain of Liguanea, or that which commonly passes by that name. In this division are Port Antonio, Morant Bay, and the harbour of Kingston. Kingston is a considerable city and a place of great trade, with a population of more than 33,000 persons of all descriptions. It is regularly built, and contains many good houses, two churches, and some charitable institutions; also five schools. The harbour is protected by the narrow slip of land on whose western extremity Port Royal is built. The greatest part of the produce of the southern districts is sent to Kingston and hence exported to Europe or America. Port Royal, once the capital of the island, has been repeatedly destroyed by earthquakes, hurricanes, and fire, but is still a considerable place, as its harbour is the station for the ships of war, and it contains the naval arsenal and good fortifications. The bulk of its inhabitants are people of colour. Morant Bay, nearly at an equal distance between Port Royal and Morant Point, carries on a considerable trade and is a thriving place. The population is between 6000 and 7000. Antonio has a good harbour, but little trade.

2. The county of Middlesex occupies the central part of the island, comprehending on the south the western portion of the plain of Liguanea, or the plains of St. Catherine and St. Dorothy, with the whole of the plain of Vere and the basin of St. Thomas-in-the-Vale; also the hills enclosing these level grounds, and the hilly and mountainous country which extends along the northern shores from the mouth of the Wagwater River to Rio Bueno Harbour. On its southern coast are Port Henderson and Old Harbour; but they are only visited by small vessels, which carry the produce of the country to Kingston. On the northern shores are Annotto Bay, Maria, and St. Ann's Bay, which carry on some commerce by sea, especially Annotto Bay, where there is a small but thriving town. On St. Catherine's plain is built the town of S. Jago de la Vega, commonly called Spanish Town, which is considered the capital of the island, being the seat of government. It is a small town with about 6000 inhabitants, but embellished by the king's house (the residence of the governor) and the public offices. The superior courts sit here. It has a free-school and some charitable institutions.

3. The county of Cornwall extends over the western part of the island, comprehending the plains of Pedro and Savanna la Mar, and the hilly country lying between them and north of them. The two most frequented harbours on the southern shores, Black River and Savanna la Mar, have little trade; but on the northern coast are three thriving towns, S. Lucia, Montego Bay, and Falmouth, each containing a population of between 5000 and 8000 inhabitants. Montego Bay is the chief town of the county, and the

assize courts are held here. The harbour is exposed to a heavy swell, which sets in during the prevalence of the north winds; but a breakwater has been erected as a protection against the sea. Fifty years ago Falmouth was an inconsiderable village, but it is now nearly as large and populous as Montego Bay, and carries on a considerable commerce.

The population of Jamaica appears to be less than 400,000 souls; but it cannot be exactly ascertained, as no complete census has ever been taken. In 1834 there were 297,186 negro slaves, all of whom have been made free in this present year (1838), by separate acts of the legislatures of Great Britain and of Jamaica.

The Maroons were originally runaway slaves, partly from Jamaica itself, partly from Cuba, who lived in the forests on the northern side of the island. In 1738 a tract of land was granted to them in those parts, which they cultivated and on which they built two small towns, and though a portion of them forfeited their privileges by a rebellion, others have preserved them to this day. The other inhabitants are either whites or people of colour. The whites are either natives of Great Britain or descendants of Europeans, and probably amount to about 30,000 individuals. The people of colour, of whom there are perhaps 40,000, are the offspring of Europeans and negro women. They are subdivided into *mulattoes*, the offspring of a white and a black; *samboes*, the offspring of a black and a mulatto; *quadroons*, the offspring of a white and a mulatto; and *mestees*, the offspring of a white and a quadroon. No traces of the native population of the island existed when it was taken by the English from the Spaniards.

The people are occupied either in agriculture or in trade. The following tables show the share which every town has in the trade of the island, and the imports and exports, and their value in sterling money for the year 1834.

The imports into Jamaica in the year 1834 amounted to 1,589,720*l*. Some of the largest articles in amount were apparel and slops, beef and pork, butter, grain and flour, cotton articles, salted fish, glass, hardware and cutlery, iron, wrought and unwrought, hats, leather, linen articles, soap, stationery of all sorts, wine, wood and lumber, and woollen articles. The value of books imported was only 3755*l*. The exports from Jamaica during the year 1834 amounted to 3,148,797*l*. The chief articles were arrowroot, coffee, colonial and foreign cotton manufactures, dye and hard woods both of the growth of the island and imported, ginger, iron and steel manufactured articles, linens, molasses, pimento, sarsaparilla, spirits, rum and shrub, sugar colonial and foreign, tobacco unmanufactured, tortoiseshell, and woollens.

Towards the end of the last century and in the beginning of the present Jamaica was the entrepôt of the immense quantity of European merchandise which was destined for consumption on the Spanish Main and the Spanish islands, and though at present a free intercourse between these countries and Europe exists, yet a considerable quantity of British manufactures is still sent to Jamaica, and thence to Mexico, Central America, New Granada, and Venezuela. Dye and hard woods, indigo, and other articles are sent in return to Jamaica. The Americans of the United States also carry on a considerable trade with this colony, which they furnish with lumber and provisions, taking in return rum and molasses. But by far the most important commerce of Jamaica is that with the mother-country. The time when the ships arrive from Great Britain is from October to May, and they continue to depart as they get freighted, from April to the first day of August, after which day, and until the hurricane months are over, ships and their cargoes sailing for Great Britain pay double insurance.

Jamaica was discovered by Christopher Columbus on his second voyage, the 3rd of May, 1494, but was not settled by the Spaniards before 1510. In 1655 it was taken from the Spaniards by the English, who for some time did not ap-

preciate its value; at present it may be considered as the most important possession of any European nation in the West Indies. Since 1655 it has remained in the undisputed possession of the British, and its internal peace has only been disturbed by the rebellion of the Maroons in 1795. Though Jamaica has had an assembly since 1663, its present constitution was only completed in 1728. The executive is in the hands of the governor, who, as well as the council, consisting of twelve persons, is appointed by the king of Great Britain. The governor has the chief civil and military authority. The council constitutes the Upper House. The Lower House, or the Assembly, is composed of forty-five members, chosen by the freeholders, two from each of the 21 parishes; Spanish Town, Kingston, and Port Royal send one member each.

There is a Bishop of Jamaica whose see comprises the Bahamas and Honduras. Besides the clergy of the Established church, who have the care of the several parishes, there are Scotch, Presbyterian, Wesleyan, Baptist, and Moravian ministers.

Education is in a low state in the island. Most of the opulent persons send their children to England to be educated. According to an official Report presented to the British Parliament in 1834, the total number of children in the schools was 2019; of whom 133 were whites, 1365 were free persons of colour, and 521 slaves. Out of this number of 2019, only 1035 were taught writing and arithmetic in addition to reading and scriptural instruction. It must be observed however that this Report cannot be implicitly depended upon, and is also defective. The Report only comprises 12 parishes out of the 21; and does not include either Kingston or Spanish Town.

(Bryan Edwards, *History of the West Indies;* Stewart's *Past and Present State of Jamaica; Jamaica as it was, as it is, and as it may be;* De la Beche, in the *Geological Transactions,* 2nd series, vol. ii.; *Tables published by the Board of Trade.*)

JAMES, SAINT, THE EPISTLE OF, one of the books of the New Testament. There are at least two individuals of the name of James mentioned in the New Testament.

1. *James*, one of the Apostles, son of Zebedee, and brother of the apostle John (*Matt.* iv. 21; x. 29; *Mark,* i. 19, 29; iii. 17; x. 35; xiii. 3; *Luke,* v. 10; vi. 14; ix. 54; *Acts,* i. 13), who was chosen with Peter and John to accompany Christ to the Mount of Transfiguration (*Luke,* viii. 51; *Matt.* xvii. 1). He was beheaded at Jerusalem by order of Herod Agrippa about A. D. 44 (*Acts,* xii. 1, 2). He could not have been the author of the epistle; since it bears marks of having been written at a later period.

2. *James* 'the Less' as he is called in *Mark,* xv. 40, the son of Alphæus and Mary (*Matt.* x. 3; xxvii. 56; *Mark,* xv. 40) was also one of the apostles (*Matt.* x. 3; *Mark,* iii. 18; *Luke,* vi. 15; *Acts,* i. 13).

There is also mentioned in the New Testament a James, a brother of Jesus (*Matt.* xiii. 55; *Mark,* vi. 3); who according to Josephus (*Antiq.,* xx. 9, § 1) was put to death by the high-priest Ananias about A. D. 62 or 63. He was probably the same individual as the James who appears to have had the greatest influence in the church at Jerusalem (*Acts,* xv. 13; xxi. 18; *Gal.* ii. 12); and who, according to ecclesiastical tradition, was the first bishop of that church. Since James is also mentioned by St. Paul (*Gal.* i. 19) as one of the apostles, and as the Lord's brother, we meet with three individuals of the name of James who are said to be apostles; which is contrary to the lists of the apostles given in the Gospels. It was therefore supposed by the fathers, and has also been maintained by most modern divines, that James the son of Alphæus was the same person as James the brother of our Lord; and that the Greek word (ἀδελφός), which is translated 'brother' in our version, is used, like the Hebrew אָח, in the sense of 'cousin.' The epistle is almost universally attributed to this James by the Fathers and modern critics; it was probably written shortly before his death.

The Epistle is addressed to all the Jewish Christians 'which are scattered abroad' (i. 1); and its principal object is to exhort them to perseverance; to inculcate several moral lessons of great importance, and especially to explain the doctrine of justification by faith, which many persons appear to have misunderstood.

The canonical authority of this Epistle has been much disputed. Clement of Rome (1 *Corinth,* x) and Irenæus (*Hæres.,* iv. 16, § 2) had probably read it, but they do not quote it as of inspired authority. Eusebius places it among the *antilegomenai,* that is, writings which were not generally received, and also mentions several doubts which were entertained against it. Origen speaks of it as the Epistle said to be written by St. James. After this period it was generally received by the church, till the time of the Reformation, when its canonical authority was rejected by Luther and several other reformers on account of the difference, real or supposed, which was thought to subsist between the writings of St. Paul and those of St. James, in reference to the doctrine of justification by faith. The principal argument in favour of the canonical authority of this Epistle is in its forming part of the Peshito, that is, the Syriac version of the New Testament, which was made at the latter end of the first or the beginning of the second century of the Christian æra.

(The Introductions of Eichhorn, De Wette, Hug, Michaelis, and Horne; Herder, *Briefe zweener Brüder Jesu,* 1775; and the Commentaries of Schulthessius (1828), Gebser (1828), Schneckenburger (1832), and Theile (1833).

JAMES I., King of Scotland, was a younger son of King Robert III., who, hearing of the licentious conduct of his other son, David prince of Scotland, directed Robert duke of Albany, the boy's uncle, to seize him and keep him a prisoner till he promised amendment. This foolish order was readily obeyed by Albany, who wished nothing better than an opportunity to usurp the throne; and in a short time the prince died of dysentery, as it was said, but in truth of hunger in confinement. The king now began to fear Albany; and accordingly had his remaining son James secretly put on board a vessel for France. He did not escape however; for when but a short way on her voyage the vessel was taken by an English ship of war, and the prince carried prisoner to London. His weak old father was so affected by the news that in a few hours after he died of a broken heart. The duke of Albany was thereupon made Regent of the kingdom.

James, now in the 13th year of his age, was on the 14th April, 1405, conducted to the Tower, where he was detained till the 10th June, 1407, when he was removed to the castle of Nottingham. He was carried back to the Tower again on the 1st March, 1414, but a few months afterwards he was taken to Windsor, where he remained till the summer of 1417, when King Henry V. took him with him on his second expedition to France. The Duke of Albany died in 1419, and from that time measures began seriously to be taken for his release. During all this period James was receiving the best education which could be procured. He became familiar with sights of regal pomp and power, and with the manners and customs of the English court, at a time when there was much to interest and captivate the youthful mind: his habits were active, his conduct prompt and resolute, and at his return to his native kingdom he was in the spring and vigour of his life. He was long afterwards remembered in Italy as the inventor of a plaintive sort of melody, which had been admired and imitated in that country: he was one of the best harpers of his time, and excelled all the Irish and Scotch highlanders in their use of that instrument; and in the three pieces of his which have come down to our day—*Christ's Kirk on the Green, the King's Quhair* (or Book), and *Peebles at the Play*—we have no mean specimens of intellectual power and literary skill.

At his accession, in 1424, Scotland was in many respects a perfect contrast to England: it was in fact rather an aggregate of rival powers than a settled and united kingdom. There were still two Justiciars of co-ordinate authority, one on the north and the other on the south of the Forth; and in the former portion of the realm, which alone was properly denominated *Scotland,* and where the seat of authority still principally lay, there were numerous and powerful clans. The regencies, in the absence of James, had contributed to the national disorder—the two Albanies sacrificing to their own ambitious projects the just authority of government and the supremacy of the law.

James entered on the administration of his kingdom with a spirit and energy suitable to the high notions of prerogative which he had imbibed. Immediately on his arrival he proceeded against the family and adherents of the late regents, and eventually had several of them condemned and forfeited. All the customs of the realm, great and small, were annexed to the crown; and every valuable mine of

gold or silver. A new coinage was struck, of like weight and fineness with the money of England; hospitals were to be visited and reformed; idleness and begging were forbidden; the law records of the kingdom (which seem to have been in a state of neglect) were to be inspected and ascertained; and the statutes of parliament were ordered, for the first time, to be regularly enrolled. This was not all however; for in the spirit of King Henry IV.'s time, which had witnessed some detestable examples of religious persecution, an act was passed *anent heretics*, that inquisition be taken by every bishop in his diocese, and, 'gif it misteris,' that secular power be called in support and aid of the church. In his time the chancellor and clergy first got a footing in the administration of the common law. This was in the year 1425, when the chancellor and certain persons of the three estates chosen by the king were empowered, under the name of the Court of Session, to hear and finally determine all complaints, causes, and quarrels competent before the king and his council.

We have already alluded to the king's conduct towards the family and friends of the regent Duke of Albany immediately on his accession to the throne. At a later period of his reign we have another signal instance of the king's energy and promptitude of purpose in his conduct toward the Lord of the Isles. About the year 1427 the Lord of Isla was slain by a person of the name of Campbell, who had, it seems, a commission from the king to apprehend Isla; but, it is added, he exceeded his powers in putting that chieftain to death. The circumstance occasioned great disturbance throughout the highlands and isles. Determined to restore order, and to enforce the laws in those wild districts, the king summoned a parliament at Inverness, to which the Lord of the Isles and the other highland chiefs were cited to appear. On their arrival, to the number of about forty, they were seized by a stratagem of the king, and committed to prison in separate apartments. The Lord of the Isles and some others were at length liberated; but deeply feeling the indignity he had suffered, the Lord of the Isles, immediately on his return home, gathered together his friends and vassals, and at the head of a vast force wasted all the crown lands near Inverness, and made an attempt also to destroy the town. Information of this inroad being communicated to the king, orders were instantly given to repair to the spot; and leading his troops in person, he succeeded by forced marches in coming up with the rebels in Lochaber, at a time when they least expected such a thing. The consequence was that at length the rebels made an unconditional surrender, and the Lord of the Isles was obliged to make his submission on his bended knees at the court of Holyrood House.

The king's vigour and determination were not a little obnoxious to the nobles, who saw in it the speedy ruin of their usurped authority. But it is probable that his devotion to the ecclesiastics wounded them more keenly than all the exercise of his royal power. They felt humbled, not so much before the sovereign as before the clergy. A conspiracy was accordingly formed against him, under the Duke of Athol, the king's uncle, and on the 21st February, 1437, the king was murdered, in the 44th year of his age. A year or two afterwards also his advisor Wardlaw, bishop of St. Andrew's, died; and immediately on this event Bishop Cameron, Wardlaw's favourite, was turned out of the chancellorship which he had held from the institution of the Court of the Session, and Sir William Crichton, a layman, and the first who had held the great seal for a long period, was constituted chancellor; the Court of Session expired, and the course of the old common law was re-established.

JAMES II., King of Scotland, only son of James I., succeeded to the crown when but about seven years old. The rivalry which existed between the nobles and ecclesiastics at his father's death continued; and the one party or the other prevailed according as by violence or stratagem they obtained possession of the king's person. Disorder naturally spread throughout the kingdom, and the power of individuals grew most insolent from neglect to enforce the laws. The Earl of Douglas in particular erected a sort of independent principality in the country, and forbidding his vassals and dependents to acknowledge any authority save his own, he created knights, appointed a privy-council, named officers, civil and military, and appeared in public with a splendour and magnificence more than royal. To add to the calamities which the nation suffered, the country was visited by a plague, and there was also a great famine. The king was immature in mind as in years, and altogether deficient in the vigour necessary in his circumstances and situation: his partialities were also misplaced. During his whole reign the country was disturbed by intestine broils, and though continual executions and forfeitures took place yet no regular or effectual measure was adopted to obtain or secure peace. He was also attacked from England, and at the siege of Roxburgh, which was occupied by the English, he was killed by the bursting of a cannon near him. This was in the year 1460, and in the 29th year of the king's age.

JAMES III., King of Scotland, was, like his father James II., about seven years old at his accession to the throne, 3rd August, 1460. He had scarcely begun his reign when Donald, the Lord of the Isles, seeing the weakness of government and the distracted state of the kingdom, assembled a council of his friends and vassals at his castle of Ardtornish, and in the style of an independent prince granted a commission to ambassadors to confer with deputies from Edward IV., king of England, with a view to the settlement of the realm. The commissioners met at Westminster, and after a negotiation, concluded a treaty, dated at London, 13th February, 1462, the object of which was no less than the conquest of Scotland by the vassals of the chieftain and the auxiliaries to be furnished by Edward, with such assistance as could be given by the banished earl of Douglas. While this rebellion was going on in the north, Robert lord Boyd, one of the lords of the regency, and also lord-justiciar south of the Forth, and lord-chamberlain of the kingdom, was grasping in another part of the country at all the chief honours and places of government, and it would seem that the minor offices of magistrates and common-councilmen in the several burghs were also then objects of tumultuous contest; for it was at this time the act 1469, c. 29, was passed, by which the entire system of burgh election was changed, on the pretence of such confusion. This act was the foundation of the *close system*, which was only remedied by the late Burgh Reform Act for Scotland. The same year the act 1469, c. 30, was passed, subjecting all notaries to the examination and authority of the Ordinary. This act was passed to please the clergy, who had the ear of the king. The latter indeed appears to have been the known slave of his ecclesiastics; and Sir James Balfour (*Annals of Scotland*, an. 1481), records a trick played off upon him by King Edward IV. of England, who trimmed up a person in the habit of a papal legate, and sent him to James with injunctions and excommunications in the name of his Holiness. The imposition succeeded completely. The king took up also with low favourites, and on their account involved himself in a quarrel with his nobles, which ended in the encounter at Bannockburn. The king fled in fright from the field, and falling from his horse was *harled* into a miller's cottage, where, on being discovered, he was secretly killed and carried off, nobody knew where (Pitscottie, 220). The king's death took place in June, 1488, in the 35th year of his age.

JAMES IV., King of Scotland, son of James III., was about fifteen years old at his accession to the throne, which took place on the 11th June, 1488. He was of an active disposition, full of life and vigour; and in his time the commerce and literature of the country flourished under his encouragement. But though he possessed not a few of the elements of a great mind, he unfortunately became the slave of superstition, and thence in his public conduct a meer tool in the hands of his clergy.

In 1494, having fallen into a state of melancholy on the reflection that he had countenanced the rebellion in which his father perished, he received a legate from the pope, and, in obedience to him, bound about his waist an *iron belt*, to be worn in penance, day and night, for the remainder of his life. Sometime after this his queen fell sick, and immediately thereupon he made a pilgrimage to St. Ninian's in Galloway, on foot, for her recovery, and she having afterwards recovered, they both went thither in pilgrimage the same year. That year also he went to St. Duthin's in Ross —which was to the extreme north of the kingdom, as the other shrine was at the extreme south; and we cannot hesitate to think it was at the desire of the ecclesiastics that he made those repeated progresses to the highlands and isles in which we find him engaged, with the ostensible purpose of quieting that part of the realm, but in fact to remove him from the seat of authority and government. In the meantime the clergy were not idle. In the above year, 1494, the

university of Aberdeen (the third of the Scottish universities) was founded; and in the same year an act was passed in parliament, enjoining all barons and freeholders of substance to put their eldest sons to grammar learning, and thereafter for three years to the universities to study the canon and civil laws. In 1503, while the archbishop of St. Andrew's was lord chancellor, the court of *Daily Council* was instituted—a court of the same nature and extensive jurisdiction as the previous Court of the Session, composed of the chancellor and others appointed by the crown; and the same year an act was passed subjecting all notaries to the examination of the Ordinary. In 1512 a great council of the clergy was held at Edinburgh, where the famous *Valor beneficiorum*, called 'Bagimont's Roll,' was made up. The following year the king, taking up the French cause, entered, with the flower of the kingdom, on the fatal field of Flodden, where he perished. [HENRY VIII., p. 132.]

JAMES V., King of Scotland, son of James IV., was little more than a year old when the crown devolved upon him. But so equally poised was the balance of power in Europe at this time, that as the favour of Henry VIII. of England was anxiously sought by the rival monarchs of Germany and France, so all three courted the favour of James's government. The state of the papal see was also peculiar at this time; for besides the risks which it ran from the collision of temporal interests, it was now raising up for itself determined enemies within its own dominions. The reforming spirit of Martin Luther and his followers spread into Scotland, and introduced new elements of discord into a country then in a singularly distracted state. The regency of the young king was long an object of ambition; and in the struggle every thing was forgotten by the contending parties but success. The king was besieged, captured, and re-taken; and personal rencountres between nobles and their vassals in the streets of the metropolis were of frequent occurrence. The loss of laymen however at Flodden had given a decided advantage to the clergy, and the ecclesiastical interest at last bore undisputed sway. Gavin Dunbar, who had been the king's preceptor, was made archbishop of Glasgow in 1524; in 1528 he was appointed lord chancellor; and in four years afterwards the Court of Session was erected—a court of general and supreme jurisdiction under the chancellor. The latter was now at the head both of the church and common law; and when Cardinal Beaton became chancellor, his vast powers were exercised with such force and rapidity as threatened and well nigh accomplished the extermination of every power in the kingdom but his own and the papal. It was a matter of course that all attempts at an alliance with the king by King Henry VIII., who had become embroiled with the papacy, should be rejected. A war was thus provoked, and James was obliged to court those nobles whom it had been the policy of his court to humble. They now determined on a disgraceful revenge. In an attack on the Scottish border the English were repelled, and an opportunity offered to the Scots of cutting off their retreat. The king accordingly gave orders to that end, but his barons obstinately refused to advance; and in a subsequent engagement 10,000 of the Scots deliberately surrendered themselves prisoners to the enemy. The spirit of James sunk under his contending passions, and he died of a broken heart, in the 33rd year of his age.

JAMES I. of England, and VI. of Scotland, was the only offspring of Mary queen of Scots by her second husband Henry Stuart, lord Darnley, who, through his father Matthew Stuart, earl of Lennox, being descended from a daughter of James II., had some pretensions to the succession of the Scottish throne in case of Mary dying without issue, and who was the grandson, as Mary was the granddaughter, of Margaret Tudor, through whom the Scottish line claimed and eventually obtained the inheritance of the crown of England after the failure of the descendants of Henry VIII. The son of Mary and Darnley (or king Henry, as he was called after his marriage), was born in the castle of Edinburgh, 19th June, 1566, and was baptized according to the Catholic ritual in Stirling Castle, on the 17th of December following, by the names of Charles James. The murder of Darnley took place on the 18th of February, 1567; and was followed by Mary's marriage with Bothwell, 15th May of the same year; her capture by the insurgent nobles, or lords of the congregation as they called themselves, at Carberry, 14th June; her consignment as a prisoner to the castle of Lochleven, on the 17th; and her forced resignation of the crown, on the 24th of July, in favour of her son, who was crowned at Stirling on the 29th as James VI., being then an infant of little more than a year old.

The circumstances of the time, which was that of the final struggle in Scotland between the two great interests of the old and the new religion, which besides their intrinsic importance were respectively identified with the French and the English alliance, and also with the old and the new distribution of the property of the kingdom, made the minority of James stormy beyond even the ordinary use and wont of Scottish minorities. Before his mother's marriage with Bothwell he had been committed by her to the care of the earl of Mar, a nobleman of the most estimable character, who had retired with his charge to Stirling Castle, and there resolutely withstood all Bothwell's attempts to obtain possession of the infant prince. Here he continued to reside during the regencies of the earl of Murray (22nd August, 1567—23rd January, 1570), of the earl of Lennox (27th January, 1570—4th September, 1570), of the earl of Mar (6th September, 1570—29th October, 1572), and of the earl of Morton (24th November, 1572—10th March, 1578), his education being placed under the general direction of Mar's brother, Alexander Erskine, under whom were employed George Buchanan and three others of the most distinguished among the Scottish scholars. After his brother's death not only the custody of the king's person, but also the command of the castle, were left in the hands of Erskine, and principally by his management, in concert with the earls of Argyle and Athol, a plot was arranged in the beginning of the year 1578, the result of which was that at a council composed of nearly all the nobility of the kingdom, which met at Stirling, James, young as he still was, was requested to take the government into his own hands, and Morton was compelled to resign the regency at Edinburgh on the 10th of March, to the great joy of the nation, with whom the severity and rapacity of his administration had made him universally odious. Affairs were now nominally administered by the king, assisted by a council composed of twelve of the nobility. The new government however soon became unpopular, principally from the presumed or notorious inclination of its leading members in favour of popery; and this state of things in a few weeks opened a way for Morton to the resumption of nearly all his former authority. Into the hands of this man, undoubtedly one of the chief actors in the tragedy of his father's murder, the young prince now fell; and Morton succeeded in retaining his prize, notwithstanding all the efforts of the opposite party, till, partly by force, partly by skilful negotiation, he had apparently re-established his power on a foundation of complete security. It was not long however in being undermined, chiefly by the intrigues of two individuals, who seem to have first made their appearance at the Scottish court in the latter part of the year 1579, and immediately became the objects of the unbounded fondness of the young king. One of these earliest of James's succession of favourites was Esmé Stuart, a son of a younger brother of the earl of Lennox, and therefore a near relation of his own: he was a native of France, and bore in that country the title of Lord D'Aubigny, to which James rapidly added the Scottish honours of Lord Aberbrothock, earl of Lennox, and then duke of Lennox, with the appointments of governor of Dumbarton Castle, captain of the royal guard, first lord of the bedchamber, and lord high chamberlain. The other, a much darker character, was a Captain James Stuart, the second son of Lord Ochiltree. On the 30th of December, 1580, the mind of the king having been previously prepared for what was to be done, Captain Stuart entered the council chamber, and formally accused Morton of having been accessory to the murder of the late king Henry. The earl was immediately committed to prison, and notwithstanding the most strenuous efforts in his behalf by the English queen, he was brought to trial before the court of justiciary, condemned, and executed at Edinburgh, 2nd June, 1581. The two favourites, Lennox, and Stuart, recently created earl of Arran, were now the rulers of the kingdom, and they exercised their uncontrolled power with unmeasurable insolence. At length a party of the nobles, including the earls of Mar, Glencairn, and Gowrie, lords Lindsay, Boyd, and others, concerted a scheme for seizing the king's person, which they carried into effect, 12th August, 1582, at Gowrie's Castle of Ruthven, in Perthshire, whence the enterprise is known in Scottish history by the name of the Raid of Ruthven. On this revolution Arran was thrown into confinement, Lennox was ordered to leave

the kingdom, and soon after died in France, and James himself remained a captive in the hands of the conspirators, whose proceedings immediately received the full approval of a convention of the estates. They had also the active though unavowed support of Queen Elizabeth, who in the overthrow of the government of Morton and the ascendancy of Lennox and Arran had seen her whole policy with regard to the northern kingdom thwarted. On the other hand Henry III. of France interposed his influence, though unsuccessfully, to rescue the Scottish king from the thraldom in which he was now kept.

James remained in a state of restraint amounting almost to actual imprisonment for about ten months. At last, on the 27th of June, 1583, having been permitted to go from Falkland to St. Andrew's, he contrived, with the assistance of some friends, with whom he had arranged his plans, to throw himself into the castle there, and to maintain his position till the faction of his enemies, finding themselves outnumbered by those who flocked from all parts to his assistance, threw down their arms and gave up the contest. One of the king's first acts after he recovered his liberty was to release and recal to court the infamous Arran, and again to commit the management of affairs to that luckless minion, whose government speedily became as harsh and arbitrary as ever. James in the first instance had evinced a disposition to follow a moderate and conciliatory course with the faction lately at the head of affairs; he had even visited the earl of Gowrie at Ruthven Castle and granted him a full pardon; but under the influence of Arran he soon changed his conduct. An act was obtained from the convention of estates declaring all those who had been concerned in the Raid of Ruthven guilty of high treason: most of them made their escape to England; but Gowrie, who relying on his pardon had made his submission, was seized, thrown into prison, tried, condemned, and sent to the block. Seeing the power of that party thus to all appearance broken for ever, Elizabeth now applied herself to form an alliance with Arran, who readily undertook that the government of Scotland should be conducted in conformity with the wishes of the English queen, and by his unbounded influence over his royal master was easily able to perform that engagement. James was induced, among other acts of subserviency, to write to his mother in such undutiful and unfeeling terms as to make Mary, in the bitterness of her resentment, threaten to leave him the load of a parent's curse. Soon after this, 29th July, 1585, a treaty of intimate alliance was concluded between Elizabeth and the Scottish king, and an annual pension of 5000*l.* was settled by the former upon the latter. A chief manager in these transactions had been a new court favourite of James's, the eldest son of the Lord Gray, styled the Master of Gray, an individual formed by nature and education for intrigue and treachery. With the view, it is supposed, of removing a formidable rival, Arran had caused Gray to be sent as ambassador to the English court, where the unprincipled politician appears to have been immediately gained over by Elizabeth, and engaged by her to act his part in forwarding her various schemes of policy with regard to Scottish affairs. One of the first uses which Elizabeth made of this new instrument was to effect the overthrow of Arran, on whose unsteadiness and caprice she felt that she never could place any sure reliance. With her connivance, the lords who had been banished on account of the Raid of Ruthven entered Scotland at the head of a force of 10,000 men, in the end of October, 1585, and advancing to Stirling, where the king and Arran were, invested the castle, on which Arran took to flight, and the king was compelled to negotiate with them upon their own terms. All their past offences were pardoned; the principal forts of the kingdom were put into their hands; and, a parliament having been called, Arran and his late associates were all dismissed from power, he himself being besides stripped of his titles and estates—the latter, chiefly the confiscated property of those whose moment of retaliation was now come. The new settlement of the government was followed by the conclusion, 8th July, 1586, of another treaty with England, by which the two kingdoms bound themselves in a league offensive and defensive against all foreign powers who should invade the territories or attempt to disturb the reformed religious establishment of either.

In October of the same year James's mother, the unfortunate Mary, after her imprisonment of nearly twenty years, was at last brought to trial, and on the 8th of February following she was put to death. Between her condemnation and her execution James had made considerable exertions to save her; in addition to solicitations and remonstrances, he took steps to obtain the aid of France, Spain, and other foreign courts in support of his demands; but his ambassador to the English court, the infamous Master of Gray, is said to have betrayed his trust, so far as actually to be the most urgent instigator of the execution, often reminding Elizabeth and her ministers that the dead cannot bite, and undertaking that no unpleasant consequences should follow from any momentary resentment which James might show. In point of fact, the Scottish king was very soon pacified; he blustered at first under the sting of the insult that had been offered him; but reflecting that by any violent course he should put in hazard both his pension and his chance of the English succession, he prudently allowed himself to be soothed by Elizabeth's hollow excuses, and continued on the same terms of friendship with her as before. Gray was indeed, on the discovery of the part he had acted, disgraced and dismissed from court. The next year James signalized his zeal in the service of his English patroness by firmly rejecting all the overtures of the king of Spain and the other Catholic powers to induce him to join them, and by co-operating zealously with Elizabeth in her preparations for repelling the attack of the Armada.

In 1589, James was married to the princess Anne, the second daughter of Frederick II., king of Denmark. He proceeded in person to Upslo in Norway, to which place his bride, after having put to sea, had been driven back by a storm, and there the marriage was solemnized on the 24th of November. James did not return to Scotland till the 20th of May, 1590. The character of Queen Anne, who survived to 1st March, 1619, is depicted in the scandalous chronicles of the time in not very creditable colours; she is represented as an eager and restless intriguer, both in politics and in gallantry; on the other hand however, Archbishop Abbot, who knew her well, and who was not likely to regard with indulgence some of the faults she is charged with, speaks of her memory with great respect. She seems to have been a person of greater energy and decision than her husband, over whom she exerted considerable influence, notwithstanding his constant doting fondness for one male favourite after another. The first memorable event that occurred in Scotland after the king's return was a daring attempt made by his relation, Francis Stuart, lately created earl of Bothwell, a grandson of James V. by his son John, prior of Coldingham. He had been committed to prison on the absurd charge, made by some unhappy persons apprehended and tortured as witches, that he had employed their art to raise the storms by which the life of the queen had been endangered on her first attempted voyage to Scotland, and the king had afterwards been so long detained in Denmark. Upon effecting his enlargement, he collected a force of his retainers, and on the night of the 27th December, 1591, entered the palace of Holyrood-House, with the design, as he pretended, of expelling the chancellor Maitland from the king's council, but apparently with still more daring intentions. The alarm was given after he had set fire to several of the apartments and had nearly made his way to where the king was; he succeeded however in making his escape, and fled to the north. The earl of Huntly having been sent in pursuit of him, took that opportunity of falling upon his private enemy the young Earl of Murray (son-in-law and heir of the late regent), and slaying him, after burning his house to the ground; an atrocity which excited the deepest popular indignation at the time, and is celebrated in Scottish song. Bothwell and all his adherents were soon after attainted in parliament; but this did not put an end either to his audacious proceedings or to the treasonable attempts of other parties. In the beginning of 1593 a new conspiracy of Huntly and the other heads of the popish faction was detected for bringing a Spanish force into the kingdom, with the object of re-establishing popery and invading England; and a few months later, Bothwell, after having failed in another attempt to seize the royal person at Falkland, having associated himself with the remaining adherents or connexions of the late favourites Lennox and Arran, suddenly returned from England, where he had been protected by Elizabeth, and on the 24th of July, 1593, entered the palace with a band of armed followers, and made the king his prisoner. James was obliged both to grant a full pardon to the traitor and to

dismiss the chancellor Maitland and his other chief ministers; and he remained in durance till a convention of the nobles at last assembled at Stirling in the beginning of September, when his gaolers found it necessary to release him. Disturbances however were again and again excited in the course of this and the two following years by the attempts both of Bothwell and the popish lords; and at length these two factions, which had hitherto professed the most opposite principles, joining their forces, under the conduct of the earls of Huntly and Errol, encountered the royal army commanded by the young Earl of Argyle, at Glenlivat in Aberdeenshire, 3rd October, 1594, and, notwithstanding their inferiority in numbers, put it completely to the rout. This disaster however was immediately repaired by the results of an expedition conducted into the northern districts by James in person, who forced the popish lords first to retreat to the mountains, and eventually to make their submission, when they were allowed to retire beyond seas on giving security that they would engage in no further intrigues against the Protestant religion or the peace of the kingdom. Bothwell fled to France, and afterwards withdrew to Spain and Italy, where he professed himself a convert to popery, and spent the rest of his days in obscurity and indigence.

These commotions had scarcely been quieted when James became involved in new troubles in consequence of a contest into which he was brought with the clergy of the Presbyterian church, which had been legally established as the national form of religion by an act of the Scottish parliament in 1592. Although James had been induced by considerations of policy to give his assent at the moment to this popular act, he was himself an avowed admirer of episcopacy, and was even very generally suspected of a strong inclination towards popery; so that the alliance of Church and State in this case was one of a very frangible nature. To make matters worse, both parties cherished the loftiest notions of their powers and rights, each indeed looking upon itself as entitled to lord it over the other. In December, 1596, in a tumult of the people of Edinburgh, excited by the harangues of their clergy, the life of the king was placed in the greatest danger, and the decided measures that followed on both sides made the contest assume the appearance of the commencement of a civil war. Nearly all the aristocracy and the upper classes however were with the king; the clergy and the people in vain endeavoured to find one of the nobility who would espouse their cause and come forward as their leader; and by an unusual exertion of vigour and firmness James was enabled not only completely to crush the insurrection, but to turn the occasion to account in bringing the Church into full subjection to the civil authority. In the course of the following year, 1598, the substance of episcopacy, in a political sense, was restored by seats in parliament being given to about fifty ecclesiastics on the royal nomination. Even the General Assembly was gained over to acquiesce in this great constitutional change.

The most memorable event in the remainder of James's Scottish reign was the very mysterious affair known in history by the name of the Gowrie conspiracy. On the 5th of August, 1600, James, being then at Falkland, was induced by Alexander Ruthven, a younger son of the earl of Gowrie who was executed in 1584, to accompany him with a few attendants to the house of his brother the earl of Gowrie at Perth. Some time after his arrival he was led by Ruthven into a retired apartment of the house; there a struggle took place between the two, in the presence only of the earl's steward, who was in full armour, but either did not interfere at all, or, according to his own account, only for the king's protection. Meanwhile, what was going on was perceived from the street, on which the people assembled, and the king's attendants rushed to the room: in the end the king remained unhurt, but both Alexander Ruthven and his brother the earl were killed. These are nearly all the undoubted facts of this strange transaction: they seem to establish a design on the part of the Ruthvens to obtain possession of the king's person, and there are some circumstances leading to the conjecture that they were prompted by the English government. That they intended to take his life, as James endeavoured to make it appear, the whole circumstances of the case will scarcely allow us to suppose. The passage however is one of the darkest in history, and, after the expenditure of much ingenuity in the attempt to clear it up, it may be pronounced that no explanation of it which is satisfactory at all points has yet been given, or is likely ever to be attained. Whatever was the nature of the affair, it stands isolated from all the other events of the time, and had as little effect upon anything that came after it as it is known to have had of connection with anything that went before.

In the last years of his residence in Scotland James was much occupied in taking measures for securing his succession to the English throne, an object which, from the capricious temper of Elizabeth, and other circumstances of the case, remained of doubtful attainment up to the very moment of its accomplishment. Although no party to the rash attempt which cost the earl of Essex his life in 1601, he had been previously in correspondence with that nobleman, who seems to have led the Scottish king to believe that zeal for his cause was the motive of his conduct; and after receiving the news of the ill success of his friend, James appears to have been prepared to go all lengths to save him from the block, having even ordered the ambassadors, whom he despatched immediately to the English court, to follow up their entreaties and remonstrances, if necessary, with an open declaration of war. The head of Essex however had fallen before the Scottish ambassadors reached London. Eventually Sir Robert Cecil himself became James's chief confidant; but it is remarkable that even after he had thus secured the important services of the English prime minister, James continued to hold a clandestine correspondence on the same great subject of the succession with other parties, of whose participation in the business Cecil apparently was kept in entire ignorance. (See Lord Hailes's 'Remarks on the History of Scotland,' ch. xiv.) Many of Cecil's letters have been preserved, and were published at Edinburgh by Lord Hailes (Sir David Dalrymple) in 1766, under the title of 'The Secret Correspondence of Sir Robert Cecil with James VI., King of Scotland,' 12mo.

James at length became king of England by the death of Elizabeth, 24th March, 1603, when his accession took place without a murmur of opposition from any quarter. Having set out from Edinburgh on the 5th of April, he entered London on the 7th of May, after a journey which in both countries resembled a triumphal progress. Many of his Scottish courtiers accompanied their sovereign, and the prodigality with which he distributed the wealth and honours of the kingdom among these hungry northern adventurers was one of the first things in his conduct that disgusted his new subjects. In his foreign policy James began by continuing in the same course that had been pursued by Elizabeth, entering into a close alliance with Henry IV. of France for the support of the Dutch and resistance to the aggressions of Spain. The conspiracy of Sir Walter Raleigh, Lord Cobham, and others, to place on the throne the Lady Arabella Stuart, James's cousin, was the first domestic affair of interest. [RALEIGH, WALTER.] The next business that engaged James's attention was the settlement of the disputes between the Church and the Puritans, for which purpose a conference was held at Hampton Court, in January, 1604, and the points of difference discussed in the king's presence, he himself taking a conspicuous part in the debate. [CONFERENCE.] James's first parliament met on the 19th of March, and was opened by a speech which, as Hume remarks, 'proves him to have possessed more knowledge and greater parts than prudence or any just sense of decorum and propriety.' Among other things he zealously urged the union of England and Scotland into one kingdom; but nothing came of this proposal for the present. James however, of his own authority, now assumed on his coins and in his proclamations the title of King of Great Britain. [GREAT BRITAIN.]

Peace with Spain was concluded, much to the gratification of the king's wishes, on the 18th of August this year. The great event of the year 1605 was the Gunpowder Plot. [FAWKES, GUY; GARNET, HENRY.] For some years after this the history of the reign is marked by no memorable events either foreign or domestic; but, although James still continued to govern by parliaments, various causes were contributing gradually to alienate the House of Commons from the crown, and to prepare the elements of that open contest between the two powers which broke out in the next reign. In 1612, the death of James's eldest son, Henry prince of Wales, in the nineteenth year of his age, spread a general grief through the nation, to which the prince had already endeared himself by the promise of a character which may be most shortly described as being in almost all respects—in its defects as well as in its virtues—

the reverse of that of his contemptible father. A rumour arose at the time, and has been preserved by some contemporary writers of a violent party spirit, that the prince had been carried off by poison, and not without the privacy and consent of the king; but this accusation, too monstrous to be admitted without the strongest evidence, rests upon neither proof nor probability of any kind. The death of Prince Henry was followed, 14th February, 1613, by the marriage of James's daughter, the Princess Elizabeth, with Frederick the Elector Palatine, an alliance which was attended with important results both in that age and in the next.

The ruling favourite whom James had brought with him from Scotland was Sir George Hume—whom in 1604 he created Lord Hume in the English peerage, and in 1608 earl of Dunbar in that of Scotland—a man of integrity, as well as of superior talent. The king's silly and mutable fondness however was in course of time transferred to other objects—to Philip Herbert, the second son of the earl of Pembroke, whom he made earl of Montgomery in 1605, and who many years after succeeded his elder brother as earl of Pembroke; and to another Scotchman, Sir James Hay, made a Scottish peer by the title of Lord Hay of Bewlie in 1609, and who afterwards bore successively in the English peerage the titles of Lord Hay of Sawley (1615), Viscount Doncaster (1617), and earl of Carlisle (1622), by which last he is best remembered. It is said to have been Hay who, about the beginning of the year 1610, introduced at court a young countryman of his own, Robert Carr, or more properly Ker, of a good family, but chiefly distinguished by his handsome person, an advantage which never failed to attract the king's attention and regard. Carr was immediately taken into the highest favour, made a knight of the Bath, and the next year a peer by the title of Viscount Rochester. In 1613 the young and beautiful Frances Howard, countess of Essex, having by an infamous process, in urging which the king took a part that alone ought to consign his memory to abhorrence, obtained a divorce from her husband, was married to the favourite, her previous profligate passion for whom is believed to have incited her to the proceedings by which she succeeded in dissolving her first marriage. The king on this occasion raised Rochester to the rank of earl of Somerset (November, 1613). Somerset's fall however was still more rapid than his rise. His chief friend Sir Thomas Overbury, who had strenuously exerted his influence to prevent his marriage with Lady Essex, which he represented as the sure destruction of his fortunes, was first, by the contrivance of the unprincipled woman whom he had thus made his enemy, thrown into the Tower, and soon after taken off by poison administered to him by her means, and with the privity of her husband. The crime, though suspected from the first, was not fully discovered till about two years after its commission; but in 1615 all the parties concerned in it were brought to trial, and their guilt completely established. Four persons who had been accomplices in the murder were left to the executioner; the two principals, the wretched Somerset and his wife, had their better merited punishment commuted into confiscation of their property, and imprisonment, from which they were both after some years released. Their condemnation of course threw down the earl from his place and favour at court, and he was given up with the most easy indifference, not unaccompanied with some touches of gratuitous baseness, by James, whose mind had now been taken possession of by a passion for a new object, another handsome youth, named George Villiers, who had been recently introduced to his notice. Villiers, who, after having been knighted, was created successively Viscount Villiers (1616), earl of Buckingham (1617), marquis of Buckingham (1618), and duke of Buckingham (1623), continued the first favourite and ruling minister during the remainder of the reign. [BUCKINGHAM.]

In the summer of 1617 James paid a visit to Scotland, and, having summoned a parliament, succeeded, though not without great difficulty, in obtaining the assent of that body, and also of the General Assembly, to such regulations as, along with other innovations previously made since his accession to the English throne, brought the Scottish church, in government, in ceremonies, and in its position in relation to the civil power, very nearly to the model of the English. It was now no longer a Presbyterian, but nominally as well as substantially an Episcopal church. But the popular feeling of the country was never for a moment reconciled to these enforced changes.

The year 1618 was disgraced by the execution of Sir Walter Raleigh, on the monstrous pretence of the sentence passed upon him for the conspiracy in which he had been involved in the first year of the king's reign, but in reality as a sacrifice to the court of Spain. [RALEIGH.] But the public indignation at James's subserviency to that Catholic power was roused to a still higher pitch by the great foreign events of the two following years, when, Austria assisted by Spain having attacked the Bohemians, who had chosen the Elector Palatine for their king, James not only refused to take part with his son-in-law and the Protestant interest on the Continent, of which he was thus installed as the champion, but even refused to acknowledge his new regal title. Frederick was soon driven both from his acquired and his hereditary dominions by the arms of the Catholic powers confederated against him, and obliged with his family to take refuge in Holland. Staggered by this sudden catastrophe, and by the vehemence with which the people expressed their rage and grief, James now hastened to take some steps to repair the disasters which his pusillanimity and inaction had mainly occasioned. After endeavouring to raise money in the way of a benevolence, he found himself obliged to call together a parliament, the first that had been allowed to meet for six years. In this parliament, memorable among other things for the impeachment of Bacon [BACON, FRANCIS], the first decided stand was taken by the Commons in their contest with the crown by their famous protest, passed 18th December, 1621, in reply to the king's assertion that their privileges were derived from the grace and concession of his ancestors and himself,—'That the liberties, franchises, and jurisdiction of parliament are the antient and undoubted birthright and inheritance of the subjects of England.' This resolution, which the king tore from the Journals with his own hand, was followed by the immediate prorogation and soon after by the dissolution of the parliament; several of the leading members of the House of Commons being at the same time sent to the Tower or to other prisons.

James had for some time before this set his heart upon the marriage of his son Prince Charles with a Spanish princess: the project of that match had principally influenced him to the course he had taken in the affair of Bohemia, and he now hoped by the same arrangement to be able, without having recourse to arms, to recover the Palatinate for his son-in-law. But in both these expectations he was disappointed. For some time the negotiations seemed to proceed favourably; but they were in 1623 brought to an abrupt termination, apparently by the rash interference of Buckingham, who, after having persuaded Prince Charles to proceed along with him to Spain for the purpose of expediting the matter, disgusted and quarrelled with the leading personages of the Spanish court, and then successfully exerted his influence with James, or perhaps rather with the prince, to prevent the match. As the public clamour for the recovery of the Palatinate still continued, another parliament was assembled in February, 1624, which eagerly granted supplies for the attainment of that object by force of arms; war was in consequence declared against Spain, and an army under Count Mansfeldt was sent into Germany in the latter part of the year. But this expedition turned out an utter failure; the force, reduced to half its numbers by a pestilential disorder before it had crossed the sea, never even entered the Palatinate; and that principality remained in the hands of the Emperor, or rather of the Duke of Bavaria, to whom it had been assigned, along with the electoral dignity, by the Imperial diet.

James's reign of nearly fifty-eight years in Scotland, and rather more than twenty-two in England, was terminated by his death on the 27th of March, 1625, when he was within three months of completing the fifty-ninth year of his age. As happened in the case of the death of almost every person of eminence in that and the preceding age, a rumour sprung up that he had been carried off by poison; and when Buckingham was impeached by the Commons in the beginning of the next reign, one of the charges brought against him was that the late king owed his death to some plasters and drinks which he had administered to him without the knowledge of the physicians. In fact something of this kind does appear to have taken place, although Buckingham's intentions in what he did may possibly have been innocent enough. It was even said, in the violence of party hate, that Charles himself was implicated in the poisoning of his father; and this grossly improbable imputation has re-

ceived the eager sanction of Milton. The statements upon the subject are collected in Harris's 'Life of James I.,' pp. 281-288; and 'Life of Charles I.,' pp. 21-25 (edit. of 1814).

James's children by his queen, Anne of Denmark, born 12th December, 1574, married 24th November, 1589, died 2nd March, 1619, were: 1. Henry Frederick, born at Stirling Castle, 19th February, 1594, died 6th November, 1612; 2. Robert, died in infancy in Scotland; 3. Charles, who succeeded his father as king; 4. Elizabeth, born 19th August, 1596, married to Frederick V. Elector Palatine 14th February, 1613, died 8th February, 1662; 5. Margaret, born 24th December, 1598, died in infancy; 6. Mary, born 1605, died 16th December, 1607: and 7. Sophia, born 21st June, 1606, died two days after. The Electress Sophia, the mother of George I., was the youngest of the thirteen children of the Princess Elizabeth and her husband the Elector Palatine. [George I.]

Besides the well authenticated public acts of James I., many materials may be found for the illustration of his character in the works of various writers who were his contemporaries: especially Sir Anthony Weldon's 'Court and Character of King James,' 12mo., 1651; Arthur Wilson's 'Life and Reign of King James the First, King of Great Britain,' fol. 1653, or as reprinted in the second vol. of Bishop Kennet's 'Complete History;' Sir Edward Peyton's 'Divine Catastrophe of the Kingly Family of the House of Stuarts,' 8vo., 1731; 'The Non-such Charles, his Character,' 12mo, 1651 (supposed by some to be written by Peyton); Sir Ralph Winwood's 'Memorials of Affairs of State in the Reigns of Queen Elizabeth and King James I.' fol. 1725; Francis Osborne's 'Traditional Memoirs on the Reign of King James,' in Works, 8vo., 1673, &c.; and Roger Coke's 'Detection of the Court and State of England,' 2 vols. 8vo., 1697. See also 'Dr. James Welwood's 'Memoirs of the most material Transactions in England for the last Hundred Years preceding the Revolution,' 8vo., Lond. 1700, and Glasg. 1741. Although some of the above-named writers are avowedly very unfavourably disposed to the memory of this king, and relate scarcely anything of him that is not to his discredit, there is too much ground for believing that the most severe of them have scarcely exaggerated the more despicable features of his character. Even his better qualities leaned to the side of vice or weakness; his easiness of temper was but an indolent sensuality, and his pacific disposition and aversion to war mere pusillanimity and cowardice. Of dignity or elevation of mind he had no conception; his tastes, opinions, passions, and habits were all alike low and vulgar, if indeed for some of them these be not far too gentle epithets. With such a moral nature it was impossible that his intellect could be other than a stinted one; yet his education had given him a good deal of learning, at least for a king, and although he was far from being either the profound scholar, philosopher, or divine that he supposed himself, and that he was flattered with being by his contemporaries, who called him Solomon the Second, he was certainly not destitute of some literary talent, however dashed most of the exhibitions of it were with occasional grotesqueness and absurdity. He was a voluminous author, and any account of him would be very incomplete which did not notice his various printed works in prose and verse. They have been partially enumerated by Harris, in his 'Historical and Critical Life,' and by Horace Walpole, in his 'Royal and Noble Authors;' but the fullest account that we have met with is that given by Dr. David Irving, in his 'Lives of the Scottish Poets,' 2nd edition, 2 vols., Edinb. 1810, vol. ii., pp. 207-291. His first publication, a collection of poems, under the title of 'The Essays of a Prentice in the Divine Art of Poesy,' 4to, appeared so early as 1584. About the same time also he appears to have composed his 'Fruitful Meditation,' upon part of the Revelation of St. John, which however was not printed till 1588. Of his subsequent works the following are the chief:—'His Majesty's Poetical Exercises at Vacant Hours,' 1591; his 'Dæmonologie' (a dialogue, in three books, in defence of the belief in witches), 4to., 1597; 'The True Law of Free Monarchies, or the Reciprocity and Mutual Duty betwixt a free King and his Natural Subjects' (Anonymous), 1598; 'Βασιλικὸν Δῶρον, or his Majesty's Instructions to his dearest Son Henry the Prince,' 1599 (a treatise which, on account of the doctrines it contained on church government, was censured as libellous by the synod of St. Andrew's); 'A Discourse of the Unnatural and Vile (Gowrie) Conspiracy against his Majesty's Person,' 1600 (reprinted, with notes, by Lord Hailes, 1757, and along with his 'Annals,' 1819); 'Triplici Nodo Triplex Cuneus, or an Apology for the Oath of Allegiance,' 1605 (which was answered by Cardinal Bellarmin, and produced a long controversy, and many other publications on both sides, for an account of which see a note by Dr. Birch in the Appendix to Harris's Life); 'A Premonition to all Most Mighty Monarchies, &c.' 1608 (on the same subject); 'A Declaration (in French) concerning the Proceedings with the States-General of the United Provinces of the Low Countries, in the Cause of D Conradus Vorstius' (appointed Professor of Divinity at Leyden), 1612; and 'A Remonstrance for the Right of Kings (in French), in answer to Cardinal Perron,' 1615. A collected edition of all the preceding prose works, except the Discourse on the Gowrie Conspiracy, was published, in folio, in 1616, under the title of 'The Works of the Most High and Mighty Prince James, &c., by James (Mountague), Bishop of Winton.' The volume also contained some treatises that had not before appeared, particulary 'A Counterblast to Tobacco' (this however, according to Harris, was first printed in quarto, without name or date), and 'A Discourse of the Manner of the Discovery of the Powder Treason.' A Latin translation of this collection was published under the care of Bishop Mountague, in 1619. To the works already enumerated are to be added a number of speeches to parliament, some of which are not the least curious or characteristic of the royal author's compositions; various sonnets and other short pieces of verse, in English and Latin, scattered in different collections, printed and manuscript; and a metrical version of the Psalms, published at Oxford, 12mo., 1631, in which however, according to his funeral sermon, preached by Bishop Williams, he had only proceeded as far as the thirty-first Psalm at his death. It ought also not to be forgotten, that the authorized translation of the Bible was commenced and completed under his auspices. [Bible.]

Of the changes in the law introduced in this reign the most important were effected by certain acts of the parliament which met in February, 1623. By one of these (the statute 21 Jac. I., c. 2), entitled 'An Act for the General Quiet of the Subjects against all Pretences of Concealment (of Lands belonging to the Crown) whatever,' it was enacted that no person could in future be sued or impeached by the king for any manors, lands, revenues, &c., unless it might be proved that he or his progenitors had a title to them within sixty years before the meeting of that parliament. This was a very valuable modification of the old law maxim, *Nullum tempus occurrit regi*. By another of these acts (the statute 21 Jac. I., c. 3), entitled 'An Act concerning Monopolies and Dispensations with Penal Laws,' it was declared that all charters, licences, and letters patent granted to any person by the crown to dispense with any law or statute should be void, and that all licences and privileges for the sole buying, selling, or working of anything should be void, except patents for a term not exceeding fourteen years to the authors of new inventions, and a few other existing patents, which were specially enumerated. [Monopoly.] This abolition of the dispensing power, and of the power of granting unlimited monopolies, both of which had hitherto been considered to be vested in and had been extensively exercised by the crown, was the extinction of two great practical evils. Blackstone enumerates as the chief improvements made in the administration of private justice in this reign, the abolition of sanctuaries and the extension of the bankrupt laws, the limitation of suits and actions, and the regulating of informations upon penal statutes. To this short list, it has been observed, may be added 'the statutes for extending the benefit of clergy to women in certain offences, the restriction upon costs in certain frivolous actions, and the salutary assistance afforded to magistrates in their defence to actions brought against them for things done in the execution of their office.'—*Note by Mr. Justice Coleridge to Com. IV.*, 436.

JAMES II. of England, and VII. of Scotland, was the second surviving son of Charles I. by his queen Henrietta Maria of France, and was born at St. James's, 15th October, 1633. He was immediately declared duke of York, but not formally created to that dignity till 27th January, 1643. After the surrender of Oxford to Fairfax in June, 1646, the duke, with his younger brother Henry, afterwards created duke of Gloucester, and his sister Elizabeth, was committed by the parliament to the care of the earl of Northumberland, and he continued in the custody of that

nobleman till the 21st of April, 1648, when he made his escape from St. James's Palace, disguised in female attire, and took refuge in Holland with his sister Mary, princess of Orange. Here he immediately joined a part of the English fleet which had revolted from the parliament, and was then lying at Helvoetsluys; but although at first received on board as admiral, he soon after resigned that post to his brother, the prince of Wales, on the arrival of the latter from Paris, and returned to the Hague. When Charles, now styled king by his adherents, came to Jersey, in September, 1649, he was accompanied by the duke, who remained with him during his stay of three or four months. He then returned to the Continent, and resided for some time with his mother at Paris. 'Never little family,' says Clarendon, who had an interview with him at Breda in 1650, 'was torn into so many pieces and factions. The duke was very young, yet loved intrigues so well that he was too much inclined to hearken to any men who had the confidence to make bold propositions to him. The king had appointed him to remain with the queen, and to obey her in all things, religion only excepted. The Lord Byron was his governor, ordained to be so by his father, and very fit for that province, being a very fine gentleman, well bred both in France and Italy, and perfectly versed in both languages, of great courage and fidelity, and in all respects qualified for the trust; but his being absent in the king's service when the duke made his escape out of England, and Sir John Berkley being then put about him, all pains had been taken to lessen his esteem of the Lord Byron; and Sir John Berkley, knowing that he could no longer remain governor when the Lord Byron came thither, and hearing that he was on his journey, infused into the duke's mind that it was a great lessening of his dignity at that age (when he was not above fourteen years of age, and backward enough for that age) to be under a governor; and so, partly by disesteeming the person, and partly by reproaching the office, he grew less inclined to the person of that good lord than he should have been.' (*Life*, i. 284, edit. of 1827.) Shortly before his meeting with Clarendon it had been reported that Charles, then in Scotland, was dead; upon which the duke, looking upon himself as almost already king, had set his mother's authority at defiance, and left Paris for Brussels, with the view of taking counsel, as to what he ought to do, with the duke of Lorraine. When the falsehood of the intelligence about Charles was discovered, he and the advisers by whom he was attended resolved upon going to the Hague; 'and when they had wearied all people there,' says Clarendon, 'they came to Breda, where the chancellor had met them. The duke himself was so young that he was rather delighted with the journeys he had made than sensible that he had not entered upon them with reason enough; *and they had fortified him with a firm resolution never to acknowledge that he had committed any error.*' (*Ibid*, p. 290.) In the end he found himself obliged to return to his mother at Paris; and here he chiefly resided till he attained his twentieth year, when he received a command in the French army, and served for some time under Marshal Turenne. The peace concluded with Cromwell however in October, 1655, compelled him, with his elder brother, to quit France; upon which, on the invitation of Don John of Austria, the governor of the Low Countries, he retired thither, and entered the Spanish service. Both he and his brother the duke of Gloucester fought on the Spanish side at the siege of Dunkirk, which surrendered to the French in June, 1658.

At the Restoration (May, 1660) the duke of York returned to England with the king, and was immediately made lord-high-admiral and lord-warden of the Cinque Ports. The course of his conduct for the next twenty-five years forms an important part of the public history of his brother's reign, and only the leading incidents can be shortly noticed here. In September, 1660, he married Anne, the eldest daughter of the Chancellor Hyde (afterwards earl of Clarendon), to whom it was affirmed that he had been married, or at least contracted, at Breda about a year before. The lady was at any rate far gone with child when the present marriage took place, and produced a son in about six weeks, a circumstance which makes her father's professed ignorance and want of suspicion as to the whole affair the more extraordinary. For some curious details touching his behaviour when the matter was first communicated to him by the king, his 'Life,' written by himself, may be consulted. It is asserted by Burnet that the duke endeavoured to avoid the marriage, and that 'he thought to have shaken her from claiming it by great promises and as great threatenings; but she was a woman of great spirit, and would have it known that she was so, let him use her afterwards as he pleased.' This is altogether opposed to her father's account, according to whom the duke petitioned the king to give his consent to the marriage with a 'passion which was expressed in a very wonderful manner, and with many tears, protesting that if his majesty would not give his consent he would immediately leave the kingdom, and must spend his life in foreign parts.' But the delay of the step till so near the last moment does not look much like impatience on the duke's side, and rather gives ground for suspecting that there was some reluctance which it required great exertions to overcome.

The duke of York took an eager part in promoting the war with Holland, which broke out in the close of 1664, and as lord-high-admiral he assumed the command of the fleet which was fitted out, and which put to sea even before any declaration of hostilities. The motive that has been sometimes assigned for the conduct of both the brothers on this occasion is their wish to crush the Dutch as a Protestant people, and to disable them from interfering to prevent the re-establishment of popery in England. On the 3rd of June, 1665, the duke gained a great victory off Harwich over the Dutch fleet commanded by Admiral Opdam, who was killed, and nineteen of whose ships were taken or sunk, with the loss of only one on the part of the English. The death of the duchess of York took place in the thirty-fourth year of her age, on the 31st of March, 1671, hastened, as is supposed, by the neglect, if not the positive ill-usage, of her husband, who, notwithstanding his professions of zeal for religion, indulged himself in a fair share of the reigning licentiousness, and kept a mistress almost from the date of his marriage. A few months before her death the duchess had signed a declaration of her reconciliation to the antient religion; and immediately after that event the duke also publicly avowed his conversion to popery, an act which, although his concealed inclinations had been long suspected, did not fail to create a great sensation, especially as, from his brother's want of issue, he was now looked upon as Charles's probable successor on the throne.

When war was anew declared against Holland, in March, 1672, the Duke of York again took the chief command at sea. The most remarkable event of this contest was the action fought 28th May, 1672, in Solebay, off the coast of Suffolk, between the combined English and French fleets under the duke and Count D'Estrées, and the Dutch fleet commanded by De Ruyter, who attacked the allies with a very inferior force, and was not driven off till the engagement had lasted the whole day, and the English fleet had been so shattered as to be disabled from pursuing him. The French are accused of having taken little part in the affair; the object of their government, it is conjectured, having been to allow the English and Dutch to destroy each other. On the passing, in the beginning of the following year, of the Test Act, which required all officers, civil and military, to receive the sacrament according to the usage of the Established Church, the duke necessarily resigned both the command of the fleet, in which he was succeeded by Prince Rupert, and the office of lord-high-admiral, which however was assigned to a board of commissioners consisting of his friends and dependants, so that he still remained substantially at the head of the naval affairs of the country. On the 21st of November, 1673, he married Mary Beatrix Eleanora, daughter of Alphonso IV., duke of Modena, a lady then only in her fifteenth year. Before concluding this union he had paid his addresses to Susan, Lady Belasye, daughter of Sir William Armine, Bart, and widow of Sir William Belasye, the son of Lord Belasye; but that affair was broken off, partly by the obstinate Protestantism of the lady, partly by the interference of her father, who gave the king information of what was projected, when Charles sent for his brother and told him that having played the fool in making an unequal marriage once already, he ought to be satisfied without repeating the same thing in his advanced age. The lady was induced, partly by promises, partly by threats, to relinquish the claim she had, founded upon a written promise of marriage, and by way of compensation was, 25th March, 1674, created Baroness Belasye for life. She survived till 1713. On the 4th of November, 1677, the Duke's daughter Mary, then in her sixteenth year, was, greatly to the public satisfaction, mar-

ried to her cousin William, prince of Orange, the consent of her father having been obtained to this Protestant alliance by the persuasions of the king, his brother, who represented to him how much he might soften the popular hostility to him on account of his religion by so apparently strong an evidence of his liberality.

During the excitement produced by Titus Oates's Popish Plot, in 1678-9, the Duke of York by the advice of his brother retired to the Continent, and he resided at Brussels with his wife and his youngest daughter for five or six months. While he was absent the famous bill for his exclusion from the throne was twice read in the Commons, and ordered to be committed, by large majorities, and was only prevented from being passed in that house by the prorogation of the parliament, 27th May, 1679. To this date may be assigned the commencement of the open rivalry between the Duke of York and Charles's natural son the Duke of Monmouth, whose popularity with the nation, still more than the presumed partiality of his father, undoubtedly made him a somewhat formidable competitor for the succession, in the actual circumstances of the legitimate heir. For the present however the latter succeeded in maintaining the ascendency. Returning home in the beginning of September he had the satisfaction of seeing Monmouth removed from his post of captain-general and exiled, while he obtained from the king for himself the government of Scotland. Before he set out for that country however he became involved with other persons of his religion in the discredit of giving countenance to the story of the Meal Tub Plot, which the Catholics got up with the hope, in which they were grieviously disappointed, of counteracting the effects of Oates's pretended discoveries. The share which the Duke had in this business only added to the dislike in which he was held by the great body of the nation, and which was still further increased by the bigoted severity of his administration of affairs in Scotland. In November, 1780, a new exclusion bill was brought into the House of Commons, but although it was carried through all its stages in that House by great majorities, it was thrown out in the lords. The bill was again introduced in the Lower House in the following January; but the prorogation of the parliament on the 10th of that month, and its dissolution a few days after, prevented the business being proceeded with. A new parliament having met at Oxford in March, the bill was again brought forward there, and again defeated by the same expedient, this the last parliament held by Charles II. having been dissolved after it had sat only seven days.

A visit which the Duke of York paid to London in March, 1682, is memorable on account of a disaster which happened to the ship in which he sailed on his return to the north in May; it struck upon a sand-bank near the mouth of the Humber, when the Duke and a few of his attendants, among whom was Mr. Churchill, afterwards the great Duke of Marlborough, were the only persons saved. The solicitude the Duke was said to have shown on this occasion for the safety of his priests and his dogs contributed considerably to deepen the popular odium of which he was the object. Very soon after this he finally left Scotland, his government of which country had been throughout an oppressive and cruel tyranny, and again taking up his residence at the English court, became his brother's chief counsellor, and, much more than Charles himself, whose increased indolence and infirmities now more than ever indisposed him for exertion, the mainspring and director of the conduct of public affairs. To his instigation are chiefly attributed the general attack upon corporations, the executions of Russell and Sidney, and the other violent and despotic acts which crowd the two closing years of Charles's reign.

On the death of his brother, 6th February, 1685, no opposition was made to the accession of James. In his address to the privy council, he said, 'I have been reported to be a man for arbitrary power; but that is not the only story that has been made of me; and I shall make it my endeavour to preserve this government, both in church and state, as it is now by law established.' In his very first measures however the new king showed, to borrow the expressions of Hume, 'that either he was not sincere in his professions of attachment to the laws, or that he had entertained so lofty an idea of his own legal power, that even his utmost sincerity would tend very little to secure the liberties of the people.' He began by issuing a proclamation ordering the customs and excise duties to be paid as usual, although the parliamentary grant of them had expired with the termination of the late reign; and this step, it appears, he took after a secret consultation with the French minister, Barillon, with whom arrangements were soon completed for the continuance of the pension that Charles had received from King Louis, and the general dependence of the government upon that of France. (Sir John Dalrymple's *Memoirs of Great Britain*, Appendix, part i., pp. 100-113, and Fox's *History of the Early Part of the Reign of James II.*) In another direction James made an equally offensive display of his principles, by going openly and in great state to the illegal celebration of the mass; he even lost no time in sending an agent to Rome to make his submissions to the pope and to prepare the way for the re-admission of England into the bosom of the Catholic church.

He determined however to call a parliament, for reasons which he explained to Barillon partly in person, partly through the earl of Rochester, lord treasurer. 'Hereafter,' said he, 'it will be much more easy for me to put off the assembling of parliament, or to maintain myself by other means which may appear more convenient for me. . . . I know the English; you must not show them any fear in the beginning. . . . I will take good care to hinder parliament from meddling in foreign affairs, and will put an end to the session as soon as I see the members show any ill will.' By the mouth of Rochester, he observed in addition that he would be too chargeable to Louis if he should be obliged to come to him for all the supplies he at present wanted; what he was doing did not however exempt him from also having recourse to the French king for some assistance; he hoped that in the difficult beginning of his reign Louis would help him to support the weight of it; that this fresh obligation would engage him still more not to depart from the road which he used to think the deceased king his brother should have kept with regard to the French monarch; and would be the means of making him independent of parliament, and putting him in a condition to support himself without the assistance of that body, if they should refuse him the continuation of the revenues which the late king enjoyed. (Barillon's *Dispatch* of the 19th February.) When, a few days after, in compliance with these broad hints, or rather importunate solicitations, Louis transmitted bills for 500,000 livres, James expressed his gratitude in the most rapturous terms, even shedding tears as he spoke; and Rochester, Sunderland, and Godolphin hastened to Barillon to tell him he had given life to the king their master. It was readily agreed, in requital of Louis's bounty, that the chief obstacle which stood in the way of the seizure by the French king of the Spanish Netherlands should be immediately removed, by the existing treaty between Spain and England being held to have terminated with the death of Charles.

These curious details of its commencement supply the key-note to the whole course of James's disgraceful reign. All that followed flowed naturally from such a beginning. The parliament met according to proclamation on the 19th of May, and, in the usual temper of the nation at the accession of a new sovereign, was found abundantly compliant. The revenue which the king demanded was granted to him for life by the Commons, with little or no debate, and by a unanimous vote; and on almost every other subject that came before it that assembly manifested the same complete subserviency to the wishes of the court; a strong attachment to the Established church, and a still lingering horror of the popish plot, being the only dispositions on the part of the generality of the members that gave James any trouble in managing them. The influence of the court indeed had been unscrupulously employed in their election, and with so much success that James declared there were not forty of them whom he would not himself have named. A Scottish parliament, which had assembled a few weeks before that of England, responded to all the royal demands in a spirit still more slavish. Scotland indeed, by the unheard-of atrocities of the late king's government, had been now humbled for the moment almost to the point of utter despair. While the two parliaments were still sitting, both England and Scotland were invaded, the former by the duke of Monmouth, the latter by the earl of Argyle, both of whom had for some years been exiles in Holland. The disastrous issue of each of these attempts is well known. Argyle, after the dispersion of his few followers, was apprehended and executed at Edinburgh, on the 30th of June.

Monmouth, whose landing did not take place till the 11th of that month, by which time Argyle was all but an unattended fugitive, was, after having met in the first instance with a much greater promise of success than his confederate in the north had experienced, defeated, 5th July, in the decisive battle of Sedgemoor, and being two days after found concealed in a ditch, was brought to London, and delivered to the executioner on the 15th of the same month. His uncle obdurately refused to grant him either his life or even the briefest respite. The suppression of Monmouth's insurrection was followed by the savage military vengeance of Colonel Kirke, and the more revolting enormities of the western 'campaign,' as it was jocularly called by the king, of chief-justice Jeffreys. Between the two the south-western counties were strewed with the carcasses and the dismembered limbs of human beings, women as well as men, butchered by the sword or the axe.

When the parliament re-assembled in November, the king told them that in the late crisis he had employed a great many Catholic officers, and that he had, in their favour, by his own authority dispensed with the legal test of conformity to the Established Church to be taken by every person appointed to any public office. This was too much to be borne without some expressions of dissatisfaction and alarm; but the resistance of the House of Commons was exceedingly timid and feeble. A very respectful and submissive address having been answered by the king with great arrogance and violence, nothing further was done in the matter; the supplies were at once voted; and one of the members, who had ventured to observe, when the king's answer was read, that he hoped they were all Englishmen and not to be frightened by a few hard words, was even sent by a vote to the Tower for his audacity. In the Lords a more formidable opposition seemed to be threatened, to get rid of which the parliament was prorogued after it had sat for little more than a week. One of the acts of this parliament was to extinguish completely the liberty of the press by the revival of an act originally passed for two years in 1662 (the 13 and 14 Car. II., c. 33), and afterwards extended for seven in 1664 (by the 16 Car. II., c. 8); a most important piece of legislation, which yet, as Mr. Fox remarks, has been scarcely noticed by any historian.

James's persevering attempts however to establish the dispensing power, which in the particular instance he chose to begin with was an attack upon the established religion as well as upon the law, eventually involved him in a dispute with the Church, which was productive of the most important consequences. In the beginning of April, 1687, he published a declaration at once suspending and dispensing with all the penal laws against Dissenters, and all tests, including even the oaths of allegiance and supremacy, directed to be taken by persons appointed to offices civil or military. In Ireland all places of power under the crown were immediately put into the hands of Catholics. The earl of Castlemaine was at the same time publicly sent as ambassador extraordinary to Rome, to express the king's obeisance to the pope, and to effect the reconcilement of the kingdom with the holy see. In return the pope sent a nuncio to England, who resided openly in London during the remainder of the reign, and was solemnly received at court, in face of the act of parliament declaring any communication with the pope to be high treason. Four Catholic bishops were consecrated in the king's chapel, and sent to exercise the episcopal function each in his particular diocese. Even in Scotland and England, as well as in Ireland, offices of all kinds, both in the army and in the state, were now filled with Catholics; even those of the ministers and others who had shown themselves disposed to go farthest along with the king were dismissed, or visibly lost his favour, if they refused to conform to the antient religion. An attempt had already been made to compel the university of Cambridge to confer a degree of Master of Arts on a Benedictine monk. This was not persevered in; but soon after a vacancy having happened in the presidency of Magdalen College, Oxford the vice-president and fellows were ordered by royal mandate to fill it up by the election of a person named Farmer, a late convert to popery (for whom was afterwards substituted Parker, bishop of Oxford, who avowed himself a Catholic at heart), and on their refusal were cited before an ecclesiastical commission, and expelled. On the 27th of April, 1688, the king published a second declaration of indulgence to dissenters from the Established church, and commanded it to be read by the clergy immediately after divine service in all the churches. On this Sancroft, archbishop of Canterbury, and six bishops, Lloyd of St. Asaph, Ken of Bath and Wells, Turner of Ely, Lake of Chichester, White of Peterborough, and Trelawny of Bristol, met in the archbishop's palace at Lambeth, 18th May, and drew up a petition to the king, representing their aversion to obey the order, for many reasons, and especially because the declaration was founded upon such a dispensing power as parliament had often declared illegal. For this they were all, on the 8th of June, sent to the Tower, and afterwards, on the 29th, brought to trial before the Court of King's Bench, on the charge of publishing a false, fictitious, malicious, pernicious, and seditious libel, when a verdict of Not Guilty was pronounced by the jury, which was received with acclamations by the whole kingdom as a great national deliverance. This defeat however in no degree checked at the moment the infatuated king. To quote the summary of Hume, 'He struck out two of the judges, Powel and Holloway, who had appeared to favour the bishops; he issued orders to prosecute all those clergymen who had not read his declaration, that is, the whole Church of England, two hundred excepted; he sent a mandate to the new Fellows whom he had obtruded on Magdalen College to elect for president, in the room of Parker lately deceased, one Gifford, a Doctor of the Sorbonne, and titular bishop of Madaura: and he is even said to have nominated the same person to the see of Oxford.' It was in the midst of this great contest with the Church and the nation that, on the 10th of June, a son was announced to have been born to James, a piece of intelligence which was very generally received with a strong suspicion that the child was supposititious, and that the queen had never been delivered or pregnant at all. For this notion however it is now generally admitted that there was no good ground.

James's son-in-law, the Prince of Orange, had not been an unobservant spectator of what was passing in England; and to him the hopes of the English people were now very generally turned The heads of the several parties in the state, though probably with no great definiteness or complete union of views, joined in applying to him for his assistance to save the public liberties; and he at last made up his mind to comply with their solicitations. Having set sail with a fleet of about fifty men-of-war and 300 transports, having on board a land force of about 14,000 men, he landed, on the 5th of November, at Torbay in Devonshire. Before the end of that month James found himself nearly deserted by every body; all were gone over to the prince, the people, the gentry, the nobility, the army, his immediate servants and friends, even his children. In the night of the 12th December, having previously sent over the queen and the young prince to France, he embarked with a single attendant in a boat at Whitehall Stairs, with the intention of proceeding to the same country, but was driven back by contrary winds, and forced the next day to land at Feversham, from which he returned on the 16th to Whitehall. The next day the prince, having arrived with his army in London, desired James to leave the palace, on which he proceeded to Rochester, and on the 23rd embarked from that port on board a frigate, in which he was conveyed to Ambleteuse in Britanny. Hence he repaired to St. Germain's, where Louis XIV. received him with great kindness, gave him the castle of St. Germain's for his residence, and settled on him a revenue sufficient to support the expenses of his small court.

Meanwhile the English crown was settled upon the prince and princess of Orange as King William III. and Queen Mary. [WILLIAM III. and MARY.] In the beginning of March in the following year James, having sailed from Brest, landed at Kinsale, and thence immediately marched to Dublin, with a small force with which he had been supplied by the French king. A few weeks after he laid siege to Londonderry, which however he was not able to reduce, although his forces continued to encompass it for three months before it was relieved. He himself, returning to Dublin, held a parliament, and for some time continued to exercise the rights of sovereignty in that capital; but after various military operations, the detail of which belongs properly to the history of the next reign, his cause was finally ruined by the signal defeat which he received from King William in person at the battle of the Boyne, fought 1st July, 1690. [BOYNE.] He soon after returned to France, and continued to reside at St. Germain's till his death, 6th September, 1701, in the 68th year of his age.

By his first wife, Anne Hyde, James II. had the following children:—1. Charles, duke of Cambridge, born at Worcester House in the Strand, 22nd October, 1660, died 5th May, 1661; 2. Mary, afterwards queen of England; 3. James, duke of Cambridge, born 12th July, 1663, died 20th June, 1667; 4. Charles, duke of Cambridge, born 4th July, 1664, died 22nd May, 1667; 5. Anne, afterwards queen of England; 6. Edgar, duke of Cambridge, born 14th September, 1667, died 8th June, 1671; 7. Henrietta, born 13th January, died 15th November, 1669; and 8. Catherine, born 9th February, died 5th December, 1671. By his second wife, Mary of Modena, who survived till 8th May, 1718, he had, 9. Charles, duke of Cambridge, born 7th November, died 12th December, 1677; 10. Catherine Laura, born 10th January, died 4th October, 1675; 11. Isabella, born 28th August, 1676, died 2nd March, 1681; 12. Charlotte Maria, born 15th August, died 6th October, 1682; 13. James Francis Edward, prince of Wales, styled the elder Pretender, born 10th June, 1688, died at Rome, 30th December, 1765; and 14. Maria Louisa Teresia, born at St. Germain's, 28th June, 1692, died 8th April, 1712. He had also the following illegitimate issue: 1. By Arabella, sister of John Churchill, afterwards duke of Marlborough, Henrietta, born 1670, married Sir Henry Waldegrave, afterwards created Baron Waldegrave, died 3rd April, 1730; 2. By the same, James, surnamed Fitzjames, born in 1671, created duke of Berwick 1687, died 12th June, 1734; 3. By the same, Henry Fitz James, styled the Grand Prior, born 1673, died 7th December, 1702; 4. By the same, a daughter, who became a nun in France; 5. By Catherine, daughter of Sir Charles Sedley, created in 1686 countess of Dorchester for life, Catherine, born 1681, married 1699 to James Annesley, earl of Anglesey; secondly, after having obtained a divorce from him, to John Sheffield, duke of Buckingham; died 1735.

James II. employed part of the leisure of his retirement in writing an account of his own life, the original manuscript of which, extending to nine folio volumes, was preserved in the Scotch College at Paris till the Revolution, when it was forwarded to St. Omer for the purpose of being transmitted to England, but was there destroyed, having, it is said, been committed to the flames by the wife of the person to whose charge it was consigned, in her fears for the safety of her husband if it should be found in his possession. A digest or compendium however of the matter of the royal autobiography had been long before drawn up by an unknown hand, apparently under the direction either of James or his son; and this performance (of which there was also at least one other complete copy in existence), having formed the principal portion of the papers formerly belonging to the Stuart family, which were obtained by George IV. when regent, has been printed under the title of 'The Life of James the Second, King of England, &c., collected out of Memoirs writ of his own hand. Together with the King's Advice to his Son, and his Majesty's Will. Published from the Original Stuart Manuscripts in Carlton House, by the Rev. J. S. Clarke, LL.B., F.R.S., Historiographer to the King, Chaplain of the Household, and Librarian to the Prince Regent,' 2 vols. 4to., Lond. 1816.

JAMES RIVER. [VIRGINIA.]

JAMESONITE, a mineral, which occurs crystallized and massive. It consists of—sulphur 0·225, lead 0·387, antimony 0·349, iron 0·026. Its specific gravity is 5·564.

JANEIRO, RIO DE, commonly called Rio, but whose full name is S. Sebastião de Rio de Janeiro, the capital of the empire of Brazil in South America, is situated in 22° 54′ S. lat. and 43° 15′ W. long., on the western shores of a large and safe bay, called Bahia do Rio de Janeiro.

This bay is only inferior in extent to Bahia de Todos os Santos, being nearly 24 miles in length, almost north and south, 15 miles in its greatest width, and about 120 miles in circuit. Its entrance at the southern extremity is rather narrow, being formed by two rocky and projecting tongues of land, whose extremities are hardly a mile distant from one another. On the extreme point of the eastern tongue is built the fortress of S. Cruz, and on that of the western the batteries of S. Jose and S. Theodosio. At no great distance from, and opposite to, the entrance, but within the bay, is a low rocky island, Ilha da Lagem, on which also a fortress is built, so that the entrance of the bay is very well defended. The average depth of the entrance is 14 fathoms: good anchoring ground is found everywhere within the bay. As the tide rises within the bay 16 feet at full and change, some precaution is necessary to avoid anchoring in too shallow water at high tide. The bay, being at a short distance from its shores enclosed by high hills and mountains, is not exposed to any kind of wind, and in every respect is one of the best harbours on the globe. It is diversified by numerous islands and rocks, but only one of them is of considerable extent, the Ilha do Governador, situated in the northern and wider portion of the bay. Numerous rivers fall into the bay. Though all of them have a short course, most of them are navigable for a few miles from their mouth, and facilitate the transport of the produce to Rio de Janeiro.

Near the entrance of the bay, and where it is only from four to eight miles wide, the town is built on its western shore, as already observed. It extends along the shore about three miles on an undulating plain, which contains a high hill with the church of Nossa Senhora da Gloria on it. To the west of the plain rises a range of high hills called Corcovado, containing many picturesque valleys, among which that of Laranjeiras, or 'of the oranges,' is distinguished by its beauty. The substance of which the mass of the hills round the town is composed is gneiss, in which numerous quarries are opened near the city. The gneiss is intersected by granite veins varying in thickness from two or three feet to as many inches. That part of the town which is south of the hill Da Gloria is very narrow, consisting only of one or two streets which extend south as far as the small bay of Botafogo. The city or principal town is built a little north of the hill Da Gloria, and on a rocky shore of some elevation opposite the small island called Ilha das Cobras. A fine pier of stone projects a short distance into the bay, and is ascended by a flight of steps. It leads immediately to the Palace Square, which is 150 yards long and 80 wide. Two sides of this square are occupied by the Imperial Palace, which was formed by uniting the Palace of the Viceroys, which stands on the southern side of the square, with the Convent of the Carmelites and the Senate-house by passages; the two latter buildings occupy the western side of the square. The palace has more the appearance of a manufactory than of the residence of an emperor. The northern side of the square is occupied by a row of houses two stories high, which are private property. The city itself stands on a level plain, and extends in the form of a rectangular oblong from north-west to south-east; on its northern border are five low hills. It consists of eight straight and parallel but narrow streets, intersected by many still narrower streets at right angles. A large square, called Campo de S. Anna, which joins it on the north west, divides the city from the Cidade Nova, or New Town, which extends westwards to the neighbourhood of the royal villa of S. Christovão.

The streets are paved, and they also have foot-pavements, which however are so narrow as scarcely to admit of two people passing one another. The houses are generally built of stone, and have two stories: the upper one is sometimes of wood: the roofs are of tiles. The latticed windows, which formerly were general, have disappeared. The town is lighted but sparingly, and only for a part of the night. The most distinguished buildings are the cathedral, and the churches De Candelaria and S. Francisco de Paula. The college, which once belonged to the Jesuits, is also a fine building; and a magnificent theatre and an Exchange in a good style have lately been erected. The most remarkable of the public buildings is the aqueduct, which brings down the water from the mountains of Corcovado (2400 feet, according to others 2100 feet, above the sea) to the town. It consists of two walls built of hewn stone, a yard from each other, the space between being arched over with bricks. The water thus brought to the town is distributed into several fountains, but not conducted to the houses, as is the case in many other towns in South America.

Rio de Janeiro contains a population of more than 200,000. The number of whites and of black slaves seems to be nearly equal; the people of colour are comparatively few in number. Most of the inhabitants are engaged in the different branches of commerce. There are some manufactures, as sugar-houses, tanneries, cotton manufactures, rum distilleries, and houses for the extraction of train oil. Several persons are occupied with cutting diamonds and other precious stones. Charitable institutions are not wanting, though they are scanty in proportion to the great population. There is a large library, an academy of arts, a military academy, an observatory, a botanical garden, and a grammar-school, and steps have lately been taken to in-

crease the number of such and similar institutions. As to the commerce of Rio, see **Brazil**, vol. v., p 268.

(Cazal, *Corografia Brasilica;* Henderson's *History of Brazil ; Travels in Brazil of* Spix *and* Martius; Caldcleugh; *On the Geology of Rio de Janeiro,* in *Geolog. Trans.*, 2nd series, vol. ii.)

JANI'RA. [**Isopoda**, p. 55.] The word is also employed by Oken to designate a genus of *Acalephans* apparently nearly allied to the *Callianiræ*.

JANIZARIES is the name of a Turkish militia once formidable but now extinct. The origin of this body dates from the reign of Amurath, or Murad I, who, after having overrun Albania, Bosnia, Servia, and Bulgaria, claimed the fifth part of the captives, from among whom he chose the young and able-bodied, and had them educated in the Mohammedan religion, and for the military profession. These recruits, being duly disciplined, were formed into a distinct body of infantry, divided into ortas, or battalions, and they were consecrated and blessed by a celebrated dervish called Hadji Bektash, who gave them the name of Yeni Cheri, or 'New Soldiers.' They soon became the terror of the enemies of the Ottomans: being completely weaned from their friends and homes, they were enthusiastically devoted to the sultan as their common father; and a strict discipline, regular pay, and constant service gave them habits of order and obedience far superior to the irregular bodies which formed at the time the armies of the princes of Christendom. After the death of Solyman the Magnificent, and the general though gradual decay of the Ottoman warlike spirit, when the sultans no longer took the field in person, the Janizary body was no longer recruited exclusively from choice and young captives, but by enrolments of Osmanlees, who, being born and bred in the faith of Islam, had not the zeal of proselytes, and were besides connected by ties of consanguinity and friendship with the body of the people around them, and not exclusively devoted to the will of the sultan. In 1680 Mohammed IV. abolished the law by which the Christian rayahs, or subjects of the Porte, were obliged to give a portion of their children to the sultan to be educated in the Mohammedan faith and enrolled into the militia. By the original laws of their body the Janizaries could not marry, but by degrees the prohibition was evaded, and at last totally disregarded. Their children's names were then inscribed on the rolls of their respective ortas; and their relations and friends, men often unfit for any warlike service, obtained a similar honour, which gave them certain privileges and protection from the capricious oppression of their rulers. In this manner a crowd of menials, low artisans, and vagabonds, came to be included in the body of Janizaries; even rayahs and Jews purchased for money the same privilege; but all this motley crew lived out of the barracks, where only a few in time of peace were present at the appointed hours for receiving their soups or rations. Military exercises were abandoned; the Janizaries merely furnished a few guards and patroles for the city, many of them being only armed with sticks; and they never assembled as a body except on pay-day, when they defiled two by two before their nazirs, or inspectors. Still they were formidable to the government from their numbers, which were scattered all over the empire, and their influence and connexions with the mob of the capital. They repeatedly mutinied against the sultans, and obliged them to change their ministers, or even deposed them. In our own days they dethroned Selim; and in the beginning of the reign of the present Sultan Mahmood they broke out into a dreadful insurrection which lasted three days, and in which the Vizir Mustapha Bairactar lost his life. In both instances they were impelled by their hatred of the Nizam Djedid, or new troops, disciplined after the European fashion. At last Mahmood resolved to put down the Janizaries; and having for several years matured his plan with the advice of his favorite Halet Effendi, and gained over their aga and others of their principal officers, he issued an order that every orta or division should furnish 150 men to be drilled according to the European tactics. This, as he had foreseen, led to a revolt; the Janizaries assembled in the square of the Etmaidan, reversed their soup-kettles according to their custom in such cases, and, invoking the name of their tutelar saint Hadji Bektash, they began by attacking and plundering the houses of their enemies. But the body of topjis, or cannoniers, the bostandjis, or guards of the seraglio, and the galiondjis, or marines, were prepared; the sultan, mufti, and the ulemas, assembled in the mosque of Achmet, pronounced a curse and a sentence of eternal dissolution on the body of the Janizaries; the sandjak shereef, or sacred standard, was unfurled, and a general attack on the Janizaries began, who, cooped up in the narrow streets, were mowed down by grape-shot, and the rest were despatched by the muskets and the yataghans of their enemies, or burned in their barracks. About 25,000 Janizaries are said to have been engaged in the actual revolt, and most of them perished: the others concealed themselves or were exiled into Asia. This carnage took place in June, 1825, and from that time the Janizaries as a body have ceased to exist. Macfarlane, in his 'Constantinople in 1828,' gives a vivid account of that catastrophe.

JANSENISTS, a sect which appeared in the Roman Catholic church about the middle of the seventeenth century. They professed not to attack the dogmas but only the discipline of that church, which however stigmatized them as heretical in some of their tenets. They took their name from Janssen, or Jansenius, bishop of Ypres in the Netherlands, who published a book entitled 'Augustinus,' in which he supported, by means of passages from the writings of St. Augustine, certain principles concerning the nature and efficacy of divine grace which appear to partake greatly of Calvin's doctrine of predestination. This question of grace and predestination had already been discussed in the church at various times, and had proved a stumbling-block to many theologians. Michael Baius, professor at Louvain, had been condemned in 1567 by a Papal bull, and obliged to disown seventy-six propositions taken from his writings, chiefly concerning that abstruse subject. Jansenius however died quietly at Ypres in 1638, and it was not till several years after his death that some Jesuit theologians, on examining his book, discovered in it the following five propositions, which they denounced as heretical:—1. That there are certain commandments of God which even righteous men, however desirous, find it impossible to obey, because they have not yet received a sufficient measure of grace to render obedience possible. 2. That nobody can resist the influence of inward grace. 3. In our fallen state of nature it is not required, in order that we be accounted responsible beings, that we should be free from the internal necessity of acting, provided we are free from external constraint. 4. The Semi-Pelagians were heretical in maintaining that the human will has the choice of resisting or obeying the internal grace. 5. That to maintain that Christ died for all men, and not solely for those who are predestinated, is Semi-Pelagianism.

After much controversy, these five propositions were condemned by a bull of Pope Innocent X., in the year 1653, as impious and blasphemous, and the bull was received by the French prelates, and promulgated throughout France with the king's consent. Several learned men, who disliked the Jesuits and their latitudinarian system of ethics, wrote not to defend the five propositions, but to prove that these propositions did not exist in the book of Jansenius, at least not in the sense for which they were condemned. The Jesuits again appealed to the pope, and a curious question arose for the pope, which was, to determine the exact meaning of an author who was dead. Alexander VII. however, by a new bull, in 1656, again condemned Jansenius's book as containing the five propositions in the sense ascribed to them by the former bull. Arnauld and other learned men of Port-Royal persisted in denying this assumed meaning; and thus they, and all those who thought like them, received the appellation of Jansenists. A formulary was now drawn out conformable to the Papal bull, which all ecclesiastical persons in France were required to sign, on pain of being suspended from their functions and offices. A great many refused, and this occasioned a schism in the French church, which lasted many years. Arnauld, Pascal, Nicole, and other reputed Jansenists attacked vehemently the corruption, discipline, and morality of the church, and the Jesuits as supporters of that relaxation. They also inculcated the necessity of mental rather than outward or ceremonial devotion; they promoted the knowledge of the Scriptures among the people, and they encouraged general education by numerous good works which came from the press of Port-Royal. Meantime the controversy with Rome continued, although Clement IX., in 1668, entered into a sort of compromise with the French non-subscribing clergy, and Innocent XI. behaved with still greater moderation towards them. But Father Ques-

nel's 'Moral Observations on the New Testament,' published in 1698, added fuel to the flame. Quesnel, being now considered at the head of the Jansenist party, was driven into exile; Louis XIV., urged by his Jesuit confessor, suppressed the monastery of Port-Royal in 1709; and Pope Clement XI., in 1713, fulminated the bull 'Unigenitus' against 101 propositions of Father Quesnel's work. [CLEMENT XI.] A fresh contention now arose; a great part of the French clergy, many of whom were not Jansenists, including Cardinal de Noailles, appealed from the bull of the pope to a general council. The Regent d'Orléans however insisted on unconditional submission to the bull, and the recusants, or 'appellants,' were persecuted and driven into exile. This persecution made many fanatics, and Jansenism became a name for a set of visionaries and impostors. A certain Abbé Paris, who had been one of the appellants, and had died in 1727, was said to perform miracles from his tomb. For an investigation of these pretended miracles see Bishop Douglas's *Criterion, or Miracles Examined.* Next came a set of men called Convulsionnaires, who were seized with spasms and ecstasies; and others who were styled Flagellants, who whipped themselves in honour of the Saint Abbé Paris. This frenzy lasted for years, and the government by harsh measures only increased it; in fact it became mixed up with political discontent, and the parliament of Paris took the part of the appellants. [DAMIENS.] At last the paroxysm subsided, having had the effect of discrediting the name of Jansenism, which, as a sect, never afterwards revived, though its opinions are still held by many. As the original Jansenists maintained the absolute independence of the civil power on ecclesiastical authority, and as even in ecclesiastical matters they were not favourable to the supremacy of the Roman see, their principles had the effect of inducing many of the French clergy to take the oath to the constitution of 1791; these were called 'prêtres insermentés,' and were considered as schismatics by the see of Rome. The Jansenist principles extended to Italy, especially to Tuscany, where bishop Ricci and his partisans also effected a temporary schism.

JANSSEN, CORNELIUS, was born at Amsterdam, and lived several years in England. He was employed by King James I., and painted several fine portraits of that sovereign and of his children, as well as of the principal nobility. His colouring is very clear and natural; the carnations are remarkably soft, and except in freedom of hand and in grace he was esteemed equal to Vandyck, and in finishing superior to him. He generally painted on pannel, and his draperies are commonly black, which he probably chose because that colour gives greater brightness to the flesh tints. His pictures still retain their original lustre, which is supposed to be in consequence of his having used ultramarine in his black colours, as well as in the carnations. He left England soon after the arrival of Vandyck, about the beginning of the civil wars, and returned to his own country, where he died in 1665.

JANSSENS, ABRAHAM, born at Antwerp in 1569, was a competitor of Rubens, and was considered to be equal to him in many of the most important parts of the art. In colouring he was certainly inferior to Rubens alone. His compositions are spirited, his drawing correct, his pencil decided, and his draperies natural and free from stiffness. He painted subjects illuminated by torchlight, and delighted in the contrast of the most brilliant light with the deepest shade. Most of the Flemish churches possess fine pictures by this master.

JANSSENS, VICTOR HONORIUS, born at Brussels in 1664, after having been for four years painter to the duke of Holstein was sent by his highness, at his own request, to Italy, where he diligently studied Raphael and the antique, and sketched the beautiful scenery in the environs of Rome. His paintings were soon so highly esteemed that he was employed by the chief nobility of Rome. He composed historical subjects both on a large and small scale, but the latter being most sought after, he in general painted in that size. He took Albano for his model, and was superior in his own style to all his contemporaries. On his return to Brussels his pictures were as much admired there as they had been in Italy; but having a large family to support, he found it most profitable to paint large pictures; and most of the palaces and churches of his own country are adorned with his compositions. His invention was fruitful, and his execution rapid, as appears from the vast number of his works. He died in 1739.

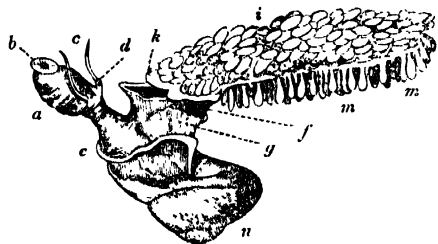
P. C., No. 799.

JA'NTHINA, or IANTHINA, Lamarck's name for a genus of turbinated testaceous mollusks of remarkable habits.

Linnæus placed the form among the *Helices*, under the name of *Helix Janthina*, between *Helix perversa* and *Helix vivipara;* and he was aware of its Pelagic distribution.

Lamarck arranges it next to *Natica*, the last genus of his *Neritaceans*, between which family and the *Macrostomes* it appears in his list of *Phytiphagous* (plant-eating) *Trachelipods.*

Cuvier assigns to the *Janthinæ* a place among his *Pectinibranchiate Gastropods*, between the *Pyramidellæ* and the *Neritæ*.



M. De Blainville elevates the group into a family, under the name of *Oxystomes*, being the fifth and last of his order *Asiphonobranchiata*. This family comes next to the *Hemicyclostomes*, which comprise the *Nerits*, &c.

M. Rang makes *Janthina* a genus of the *Trochoïds* of Cuvier, giving it a position between *Ampullaria*, Lam., and *Litiopa*, Rang.

Generic Character.—Animal with a very large *head* and a proboscidiform muzzle, at the extremity whereof is the *mouth* furnished with two vertical subcartilaginous lips (which are armed with long and very sharp points curved inwards), and with a lingual enlargement (renflement); *tentacles* two, conical, pointed, not very contractile, and very distant, each bearing at its base a rather long peduncle, which is oculated beneath its extremity; *foot* oval, divided into two parts, the anterior being concave and in the form of a cupping-glass (ventouse), the latter flattened, thick, and fleshy; *natatory appendages* lateral, rather large and fringed; *respiratory cavity* very open, and containing two pectinated *branchiæ;* orifice of the *ovary* at the bottom of this cavity; exciting *male organ* very small, and on the right side.

Shell ventricose, globular or conoid, very fragile, with a low spire, and the last whorl larger than all the rest together; *aperture* large, subtriangular, with disunited borders; the *columella* straight and long, forming the whole of the left border or lip; right border or lip trenchant, and often notched in the middle; *colour* of all the species hitherto discovered violet, more or less intense.

Operculum modified into a vesicular appendage, which serves to suspend the animal at the surface of the water, and which adheres to the posterior and fleshy part of the foot.

Janthina Fragilis (Common Oceanic Snail) Shell with the animal, the float expanded *a*, head; *b*, mouth; *c*, tentacles; *d*, eyes; *e*, border of the mantle at the entrance of the branchial cavity; *f*, foot, the posterior part, which is flat, *g*, lateral expansion of the mantle, provided for swimming, *k*, foot, anterior part forming a sort of pouch; *i*, bunch of aerated vesicles, serving to suspend the mollusk at the surface of the water, *m*, eggs suspended under the vesicular bunch; *n*, shell. (Rang)

Geographical Distribution very extensive, the form having been met with in the four quarters of the world floating on the ocean or driven on the shores by tempests. It has occurred on the coasts of our islands, but there is reason for thinking that it is not to be found in very cold latitudes. In warm climates it is very plentiful.

Habits, Reproduction, Food, &c.—Sir Everard Home published in the 'Phil. Trans.' for 1817, a paper which is appended (Appendix, No. III.) to Captain Tuckey's 'Narrative of the Expedition sent to explore the River Zaire, usually called the Congo,' wherein he describes and figures among other ova of mollusks, or *Vermes Testacea*, as he denominates them, the camerated nidus of *Helix Janthina* (pl. xiii., figs. 1, 2, 3, 4, 5, 6). 'This animal,' observes Sir Everard, 'not living at the bottom of the sea, like the Vermes testacea in general, deposits its ova upon its own shell, if nothing else comes in its way; one of the specimens of the shell of the Janthina caught in the voyage to the Congo fortunately has the ova so deposited.' And he then

refers to the drawings of Mr. Bauer, engraved as above quoted.

In the 4th vol. of the 'Journal of the Philadelphia Academy' will be found 'Remarks on the floating apparatus and other peculiarities of the genus Janthina,' by Reynell Coates, M.D. This highly interesting paper, the result of the author's personal observations during a voyage to the East Indies, establishes the correctness of Cuvier's remark, that no anatomical connexion exists between the animals and the air-cells of their float; but does not corroborate the views of Sir Everard as to the camerated nidus on the shell which he saw with so much satisfaction. Dr. Coates placed some *Janthinæ* in a tumbler of brine, and having removed a portion of the float of one with scissors, the animal soon set to work to supply the deficiency after the following manner:—The foot was advanced upon the remaining vesicles, until about two-thirds of that part rose above the surface of the water; it was then expanded to the uttermost, and thrown back upon the water, like the foot of a *Lymnæa* when it begins to swim; it was then contracted at the edges, and formed into the shape of a hood, enclosing a globule of air, which was slowly applied to the extremity of the float. There was now a vibratory movement throughout the foot, and when it was again thrown back to renew the process, the globule was found enclosed in its newly-made envelope. From this it results that the membrane enclosing the cells is secreted by the foot, and that there is no attachment between the float and the animal, other than that arising from the nice adaptation and adjustment of proximate surfaces. Dr. Coates states that the float varies in different species. In *Janthina fragilis* he describes it as convex, subcarinate above and concave beneath, straight, and composed of large vesicles: in *J. globosa* he found the vesicles smaller, and the float flat both above and beneath, added to which it is formed by the reunion of one of the edges into a spiral and nearly circular disk. In *J. exigua* it was straight, narrow, and flattened, and the vesicles were small. Along the under surface of the float a little line of pearly fibres was remarked, to which are attached the eggs of the animal.

Although Dr. Coates had no opportunity of observing the eggs of *J. fragilis*, he is strongly inclined to believe that the eggs figured and described in 'Phil. Trans.,' as above alluded to, belong to some other marine animal; and he grounds his belief on the dissimilarity between those figures and the eggs of *J. globosa* and *J. exigua*. In these two species the eggs are contained in little membranous bags of some consistence, which are attached in rows to the pearly fibres of the under surface of the float by small filamentous pedicles similar in appearance to the fibres. These bags are covered with minute, gelatinous, conical eminences, and are partially divided by incomplete septa, as may be seen by the aid of a powerful lens. In *J. exigua*, the division is very partial; but in *J. globosa* it gives to the whole sac a chambered appearance. It would seem that the animal consumed considerable time in depositing its eggs, for the bags nearest to the extremity of the float were constantly found empty, while the central bags contained young shells fully formed: those towards the animal were filled with eggs. The probability is, that the young animals when hatched ascend the float of the mother, and thus gaining access to the surface, construct the elements of their future support.

M. Rang, who also notices Sir Everard's statement, mentions it as certain that *Janthina* deposits its eggs sometimes in considerable number, as he has had occasion to remark, under the float, where they are attached by means of small pedicles; and he goes on to say, that the animal abandons them, together with the float, which is then charged with their preservation. M. Rang adds, that it is possible that, at this epoch, the natatory appendages of the mantle, being sufficiently developed, permit the animal to use them for swimming, and thus supply the loss; or one must suppose that these animals have the faculty of replacing the float. That they have that faculty we have, above, seen.

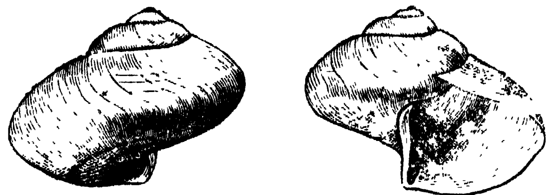
Browne, in his 'Natural History of Jamaica,' gives by no means a bad account of the floats of these animals, many of which he encountered between the Bermudas and the Western Islands, in his voyage from Jamaica. He says, 'I have observed many of the vesiculæ themselves swimming upon the surface of the water, which induced me to think that they were thrown off as the creatures retired.' Sloane also saw these oceanic snails, and figures them.

In January, 1833, Dr. Grant exhibited to a meeting of the Zoological Society of London numerous specimens of *Janthina vulgaris*, Lam., and of *Velella limbosa*, Lam., both animals of rare occurrence on the English coast, and chiefly met with floating in tropical or warmer seas. They were obtained by him at the beginning of September, 1832, in Whitsand Bay, close to the point of the Land's End, Cornwall, where they were thrown in great numbers on the sands, after a storm of three days' continuance from the north-west: they must, he observed, consequently have been floating before they were directed to the coast by the storm, in latitudes at least as high as that in which they were found. Dr. Grant regards it as probable that neither of these animals is capable of discharging at will the gaseous fluid by which they are supported on the surface of the sea; otherwise, in such a violent and continued tempest as that which stranded them, they would have emptied their vesicles and have sunk to the stiller bottom. (*Zool. Proc.*) Browne on the other hand says, speaking of the float, 'This raises and sustains it while it pleases to continue on the surface; but when it wants to return, it throws off its bladder and sinks.'

Lamarck placed *Janthina* among the plant-eaters; but in the communication by Dr. Grant above noticed, it is suggested that *Janthina*, a predaceous *Gastropod* accompanying *Velella*, as there described, may prey upon it, and acquire from it the blue colouring matter of its shell.

Several authors speak of the beautiful purple liquor which the living animal diffuses when it is touched.

We select as an example *Janthina fragilis*.



Description.—Shell pale; body whorl angulated; the base flattened, striated, and deep violet; aperture broader than long; outer lip deeply emarginate. (Swainson.)

Locality.—Oceanic in warm and temperate climates; several instances are recorded of its capture near the British Islands, and on them.

Janthina exigua has also occurred on the English and Irish coasts. (*Zool. Proc.*, 1835.)

Mr. Swainson, who in his 'Zoological Illustrations' has given beautifully correct figures of *J. fragilis* and *J. globosa*, justly remarks that the shells are so brittle that it is rare to find them perfect.

M. de Blainville is inclined to think that those shells which are notched belong to females.

Shell of Janthina fragilis.

FOSSIL JANTHINÆ?

Mr. G. B. Sowerby (*Genera*) states that he has never seen any fossil species of this genus, nor is he aware that any exist, but he refers to a fossil engraved in *Min. Con.* pl. 10, which bears a very near resemblance to it. The fossil is named, in the valuable work alluded to, *Helix carinata*, and the solid grey limetone near Settle in Yorkshire is said to be the locality. *Janthina* does not appear in the tables of M. Deshayes.

JANUARY, the first month in our present Calendar, was also the first month in the Roman Calendar. It was not the first month of the year in this country till 1752, when the legislature, by an act passed in the preceding year, altered the mode of reckoning time from the Julian to the Gregorian style. At this time it was directed that the legal year, which then commenced in some parts of this country in March, and in others in January, should universally be deemed to begin on the first of January. January derives its name from Janus. Macrobius expressly says it was dedicated to him because, from its situation, it might be considered to be retrospective to the past, and prospective to the opening year. It consists of thirty-one days, though originally of only thirty days. The Anglo-Saxons called January *Wolf-monath*. (Brady, *Clavis Calendar.*, i. 55, 56; Macrobii *Saturn.*, i. 13.)

JANUS, in mythological history, is the earliest of the Italian kings, and reigned in Latium, being contemporary with Saturn. He was succeeded by Picus and Faunus,

who, as well as himself, were worshipped by the Etruscans and Romans. Janus, by some accounts, was the son of the sun, and his attributes appear to connect him with sun-worship. He is the porter of heaven; he opens the year, the first month being named after him; he presides over the seasons, whence he is sometimes represented with four heads (Janus Quadrifrons), and his temples in that capacity were built with four equal sides, but only one entrance. He presides over production. He is the keeper of earth, sea, and sky; the guardian deity of gates, on which account he is commonly represented with two heads, because every door looks two ways; and thus he, the heavenly porter, can watch the east and west at once without turning. (Ovid, *Fast.*, i. 140.) He usually carries a key in his left hand and a staff in the other. (*Ib.*, 99.) His temples at Rome were numerous. In war time the gates of the principal one, that of Janus Quirinus, were always open; in peace they were closed to retain the wars within (*Ib.*, 124); but they were shut once only between the reign of Numa and that of Augustus. In reference to this attribute he has the epithets of Clusius and Patuleius, the shutter and opener. All his attributes, numerous and complicated as they are, appear to have reference to this notion of opening and shutting, and are explained, by those who see in Janus a modification of the sun, in reference to the phenomena of day and night, and the pervading vivifying influence of the solar rays. As to the probable origin of the word Janus, see the article DIANA.

JAPAN is an empire in Asia, which consists of an unknown number of islands of different dimensions. These islands may be considered as constituting the western boundary of the Pacific between 31° and 45° N. lat.; but the Japanese settlements on the island Tshoka, or Tarakai, better known by the name of Sakhalia, seem to extend as far north as 47° or 48° N. lat. Between these islands and the continent of Asia is a closed sea, called the Sea of Japan, which at its southern extremity is united to the Tong-Hai, or Eastern Sea of the Chinese, by the Strait of Corea, and at its northern with the Sea of Okhotzk, or Tarakai, by the still unexplored strait which divides the island of Tarakai from Manchuria. The Sea of Japan is united to the Pacific by several straits, which divide the Japanese islands from one another. The most remarkable is the Strait of Sangar between the large islands of Nipon and Yeso. Japan is situated between 129° and 150° E. long. from Greenwich. It is divided into Proper Japan and the dependent islands.

Proper Japan consists of three large islands, Kioosioo, Sitkokf, and Nipon or Nifon, which are surrounded by a great number of smaller islands. Kioosioo, the most western, may be about 200 miles long, with an average breadth of 80 miles, which would give it a surface of 16,000 miles, nearly equal to that of the island of Sardinia. On its western coast are two deep bays, that of Simabara, in the middle, which is by far the largest, and that of Omoora, north of it: at its southern extremity is the Bay of Kangosima. Kioosioo is separated from Sitkokf by the Boongo Channel, and from Nipon by the Suwo Sound and the Strait of Simonoseki. Sitkokf may be 150 miles long, with an average breadth of 70 miles; it probably contains more than 10,000 square miles, and is much larger than the island of Corsica. The long strait which divides it from Nipon on the north is in some places hardly more than a mile wide; but about the middle a large bay enters deeply into the island of Sitkokf. The eastern extremity of this island is separated from Nipon by the Bay of Osacca, which contains the island of Avasi. Nipon, the largest and the principal of the Japanese islands, has the form of a curve, or, as Kämpfer says, of a jawbone. Its length, measured along the middle of the island, exceeds 900 miles, and its average width may be estimated at more than 100 miles: its surface may therefore cover an area of about 100,000 square miles, or considerably more than that of Great Britain. Its largest bays are along the southern coast, as Osacca Bay, Mia Bay, and Yedo Bay.

The dependent countries are the large island of Yeso, with some of the Kurile Islands and the southern districts of Tarakai. Yeso has a very irregular form. Its length, from west-south-west to east-north-east, is more than 250 miles, and its average width perhaps does not fall short of 100 miles. This gives a surface of 25,000 square miles, or somewhat less than that of Ireland. Only the two southernmost of the larger Kurile Islands, Kunashir and Uturup, are occupied by the Japanese: the others belong to the Russian empire. The island of Tarakai, whose southern portion is called Tshoka, is divided from Yeso by the Strait of Perouse. It is certain that the Japanese have formed some settlements here, but it is not known how far they extend northward. According to this rough estimate, and excluding the settlements on the island of Tarakai, the Japanese empire contains about 160,000 square miles.

All these islands are very imperfectly known: not even the coasts are laid down with any degree of correctness. This arises partly from natural and partly from political causes. Nearly all the coasts are very difficult of access, being surrounded by numerous rocks and islands, and by a very shallow sea. This shallowness is most remarkable in the numerous inlets and bays with which the southern coast is indented. The harbour of Yedo, for instance, is so shallow that even small boats cannot approach the beach the larger Japanese vessels keep far out to sea, and a European ship would be obliged to anchor at five leagues' distance. The harbour of Osacca is not much better. This circumstance accounts for the smallness of all Japanese vessels, and their unfitness to keep the sea in a gale. They can only be employed in the coasting trade. The sea, besides containing numerous rocks, has some very dangerous whirlpools, two of which especially have been noticed by navigators, one near the island of Amakoosa, at the entrance of the Bay of Simabara, and the other near the southern extremity of Nipon, between the bays of Osacca and of Mia. To this must be added, that no part of the ocean is subject to heavier gales than the sea which surrounds Japan: they frequently blow with the fury of hurricanes. The government also and the laws of the Japanese are less favourable to intercourse with foreigners than those of any other country on the globe, China not excepted. If foreigners who arrive at the ports, after a delay of many days and even weeks, are at last permitted to set foot on shore, a small spot of ground is assigned to them, which has previously been enclosed with strong palisadoes. Under such circumstances our knowledge of the country must be very scanty, and we owe such as we have nearly exclusively to the circumstance that the Dutch, who are permitted to trade in the harbour of Nagasaki, are obliged to send annually an embassy to Yedo, which gives them an opportunity of examining, though very imperfectly, the southern coast of Nipon between Simonoseki and Yedo.

Some of these travellers, Thunberg for instance, assert that the whole surface of these islands is only a succession of mountains, hills, and valleys; but Kämpfer expressly says that he passed through several plains of considerable extent, as that which runs from the town of Osacca to Meaco, a distance of about twenty miles, and a similar plain west of Yedo, and extending to that town. A large plain occurs also along the northern shores of the bay of Mia, and numerous smaller plains are noticed by Kämpfer. But generally the hills run down close to the sea, or leave only a narrow strip of level ground between them and the sea-shore. Though Japan is doubtless a very hilly country, it can hardly be said to be mountainous, as by far the greatest number of the eminences are cultivated to the very top, and those few which are not cultivated are left in their natural state on account of the sterility of the soil. The Dutch have observed only one single peak of great elevation, the Fudsi Jamma, not far from the bay of Tomina, west of the bay of Yedo. They compare it in shape with the Peak of Teneriffe, and observe that the snow seldom melts on its top. According to the accounts of navigators however, it would seem that the northern part of Nipon is traversed by a continuous chain of mountains with several peaks. Volcanoes, either in an active state or extinct, are numerous, to the latter class the Fudsi Jamma seems to belong. Some active volcanoes occur on the islands scattered in the strait of Corea, as the Sulphur Island, noticed by Captain B. Hall.

From the peculiar form of these islands it may be presumed that they have no large rivers; and the rapidity with which they run down shows that the country in the interior rises to a considerable height. Many of them are so rapid that no bridges can be built over them, and they are not passed without danger. Several others are less rapid, and though they cannot be navigated, timber and wood are floated down them. A considerable number however seem to be navigable for small river-boats to a distance of some miles from the sea. The most considerable and important of those which are known is the river Yedogawa,

in Nipon, which rises in the lake of Oitz, a sheet of water sixty miles in length but of inconsiderable width. After leaving this lake it traverses the fine plain which extends from its shores to the harbour of Osacca, and in all this course it is navigated by river-barges.

We are of course very imperfectly acquainted with the climate of Japan, the meteorological observation made by Thunberg at Nagasaki only extending over one year. The southern part seems to resemble in many points the climate of England. In winter it does not freeze and snow every year, though this is generally the case: the frost and snow, when there is any, last only a few days. In January, 1776, the thermometer descended at Nagasaki to 35° Fahr., but it was considered a very mild winter; in August it rose to 98°, and that was considered as the average heat of the season. The heat would consequently be very great but for the refreshing breeze which blows during the day from the south, and during the night from the east. The weather is extremely changeable, and rains are abundant all the year round; but they are more heavy and frequent during the *satkasi*, or rainy season, which occurs in June and July. Storms and hurricanes seem to occur frequently, and the descriptions of them in Kämpfer and Langsdorf are truly terrific. Thunder-storms are also common, and earthquakes have successively destroyed a great part of the most populous towns. Only a few spots appear to be exempt from these terrible phenomena. It is observed by Kämpfer that water-spouts are nowhere of such frequent occurrence as in the seas enclosing Japan.

In no part of the world is agriculture carried to a higher degree of perfection than in Japan. All the declivities of the hills to the top, except those which are too steep, are formed into terraces or beds of different width, according to the slope, and these terraces are cultivated with the utmost care. Here, as in China, the greatest attention is paid to the collection of manure. The raising of rice is the principal object, but wheat, barley, and rye are also cultivated, though to a much smaller extent. Indian corn is not enumerated by Thunberg among the grain-crops of Japan. As the Japanese use no butter nor tallow, they cultivate *Rhus succedaneum*, *Sesamum*, and *Brassica orientalis*; the oil from the two last serves for dressing victuals, and that of the first is used for their lamps. The seeds of *Panicum verticillatum*, *Holcus sorghum*, or millet, *Panicum Corvi*, and *Cynosurus Coracanus*, are much used as food for man and beast, and cultivated extensively in some districts. Of esculent roots chiefly batatas and potatoes are raised. Other vegetables are turnips, cabbages, carrots, radishes, lettuces, melons, pumpkins, cucumbers, and gourds. Different kinds of beans and peas are raised in astonishing abundance, and several provinces have obtained a name from producing them in superior quality. Among the beans are the dadsu beans (*Dolichos Soja*), from which the Japanese make that liquid which is known in England under the name of soy. The plantations of the tea shrub are extensive in some districts, but their produce is inferior to that of China, and does not make an article for exportation. Ginger is cultivated, and the pepper shrub is planted for the consumption of the country. Their orchards are stocked with the fruit-trees of southern Europe, as oranges, lemons, medlars, figs, grapes, pomegranates; and they produce also chesnuts, walnuts, pears, peaches, and cherries; apples are not mentioned by Thunberg. The raising of cotton and silk are objects of great importance, and the *Broussonetia papyrifera* is planted extensively, its bark being used for making cloth and paper. Hemp is also much cultivated, but only employed in making cloth; the cordage is made from different kinds of nettles. Besides these different plants they plant the varnish-tree (*Rhus vernix*), from which they make the excellent varnish for their furniture, the cedar (*Cupressus Japonica*), the bamboo-cane, and the camphor-tree (*Laurus camphora*), though all these trees are also found in a wild state. They extract a blue dye-stuff from three kinds of *Polygonum*, *chinense*, *barbatum*, and *aviculare*. The authority for this account of the botany of Japan is Thunberg, from whom we have also taken the technical botanical names.

The horses are of a middling size, but strong. The number is small, as horses are only used for the saddle and by the princes. Thunberg is of opinion that there are not as many horses kept in the whole empire as in one single town in Sweden. Horned cattle are still less numerous. The Japanese do not use either their flesh or their milk, and they are only kept for drawing carts or for ploughing such fields as lie almost constantly under water. Buffaloes are found only in some districts. Neither asses nor mules are mentioned by Thunberg, but he expressly observes that sheep and goats are not kept. Swine are only found at Nagasaki, where they have probably been introduced by the Chinese, as the Japanese do not eat them. Fowls, ducks, and geese are plentiful, but principally valued for their eggs, of which the Japanese are very fond. Of wild animals only hares are mentioned by Thunberg, but he states, on the information obtained from the natives, that deer, bears, and other animals occur in the eastern and northern part of Nipon. Though the Japanese do not make much use of the flesh of domestic animals as food, they derive abundant provisions from the sea. Fish is extremely plentiful, and numerous villages are only inhabited by fishermen. Their rocky coasts are covered with oysters and several other kinds of shell-fish, and many families live exclusively on them. Even the flesh of the whale, of which some kinds are rather numerous along these coasts, is eaten.

Japan abounds in mineral wealth. Gold seems to be very plentiful in several provinces, but is not worked everywhere. The government seems to use corrective means to prevent such undertakings. Silver is not abundant; but copper, which contains a good deal of gold, is extensively worked, and supplies the most important article of export. Iron is said not to be common, but still there is enough for the consumption of the country. Some tin-mines are also stated to be worked. Salt in great quantity is made in several districts along the southern coast, where there exist salt-lagunes. Of other minerals only fine clay is mentioned, which is used in the manufacture of china; the porcelain is equal, if not superior, to that of China. The sea gives pearls and ambergris.

All travellers speak of the populousness of the country and the extent of the villages, which frequently occupy two English miles and more in length. In some more fertile districts they are so close to one another as to form nearly one contiguous street; as, for instance, in the plain which extends from the harbour of Osacca to Meaco. The smaller towns commonly contain five hundred houses, and the larger two thousand and upwards, and though they have generally only two stories they are occupied by a comparatively large number of persons.

1. The island of Kioosioo is extremely well cultivated, and generally fertile, with the exception of its eastern coast bordering on the Boongo Channel, which is mountainous, barren, and comparatively thinly inhabited. In several places there are considerable manufactures of cotton cloth, silk goods, and paper. The best known towns of importance are Nagasaki, Sanga, and Kokoora.

Nagasaki, sometimes pronounced Nangasaki, the only place open to foreigners, lies on a peninsula formed by the deep bay of Omoora, in 32° 45′ N. lat. and 129° 15′ E. long. Its harbour is spacious and deep, extending in length about 4 miles, with an average width of more than a mile. At its entrance is the small island of Papenberg, where the water is 22 fathoms deep, but it grows shallower as it proceeds inward, so that opposite to the town it has only a depth of 4 fathoms; so far it runs north-east, it then turns north, and has less depth. The town is built on its eastern shores, in a narrow valley which runs eastward. It is three-quarters of a mile long and almost as broad, and enclosed by steep though not high hills. There are some good buildings in the town, as the palaces of the two governors, and those of some princes and noblemen of the empire, but especially the temples, which were 62 in number, within and without the town, in the time of Kämpfer (1692). There are some manufactures of gold and silver. The population may amount to 15,000 or 18,000 souls. It is one of the five imperial towns of the empire.

Sanga, situated on a fine and well watered plain at the northern extremity of the large bay of Simabarra, the capital of the fertile province of Fisen, is a very large and populous town, with canals and rivers running through its wide and regular streets. It has considerable manufactures.

Kokoora, built near the entrance of the Strait of Simonoseki, has a shallow harbour, but carries on a considerable trade. The town, which in the time of Kämpfer had much decreased, was found in a thriving state in 1775, by Thunberg.

II. The island of Sitkokf has not been visited by Europeans. According to a Japanese geographer, cited by Kämpfer, it contains many mountainous and barren districts, and less fertile tracts than the other large islands.

III. Nipon, or Nifon, which constitutes the main body and strength of the empire, is, as far as it has been seen by Europeans, well cultivated and fertile, with the exception of a few barren tracts of moderate extent. It contains the largest towns, and the manufactured articles produced in this island are considered the best. The most important towns visited by Europeans, along its southern side, are—

Simonoseki, built at the foot of a mountain, on the shore of the narrow strait which bears its name, and which is only one mile and a half wide. It is not very large, but it carries on a very active coasting trade with all the districts to the east of it.

Muru, opposite to the north-eastern coast of Sitkokf, is not large, consisting only of about 600 houses; but its harbour is very safe, being well defended by a mountain running out westward from the mainland, for which reason it is resorted to by the coasting vessels, of which frequently more than 100 are anchored there. It is noted for its tanneries, where horse-hides are tanned in the manner of the Russian leather.

Osacca, one of the five imperial towns, and the most commercial place in the empire, is situated in the northern angle of the Gulf of Osacca, on the banks of the river Yedogawa, which, near the town, divides into three branches, and, before it falls into the sea, into several more. The middle or principal branch of the river, though narrow, is deep and navigable. From its mouths, as far up as the town and higher, there are seldom less than a thousand barges going up and down. Several navigable canals, which derive their water from the river, traverse the principal streets of the town, and serve as means for conveyance of goods. The banks of the river and of the canals are of freestone, coarsely hewn, and formed into ten or more steps, so as to resemble one continued staircase. Numerous bridges, built of cedar-wood, are laid over the river and canals; some of them are of large dimensions, and beautifully ornamented. The streets are narrow but regular, and cut each other at right angles; though not paved, they are very clean. A narrow pavement of flat stones runs along the houses for the convenience of foot-passengers. The houses are not above two stories high, and built of wood, lime, and clay. At the north-eastern extremity of the city is a large castle. The population is very great. According to the exaggerated accounts of the Japanese an army of 80,000 men may be raised from among its inhabitants. Many of the residents are very wealthy men, especially the merchants, artists, and manufacturers. The Japanese themselves call Osacca the universal theatre of pleasure and diversion; and plays are daily exhibited in public and private houses. In its neighbourhood the best saki, a kind of strong beer obtained from rice, is made, and exported into the other provinces.

South of Osacca, on the shores of the same gulf, is the town of Sakai, an imperial town, which however has never been visited by Europeans.

Meaco, or Kio, the residence of the ecclesiastical emperor, or Daïri, is about 20 miles from Osacca, and contained, in the time of Kämpfer, according to a census, more than 500,000 inhabitants, besides the numerous court of the Daïri. It is nearly four miles long and three wide. The Daïri resides on the northern side of the city, in a particular ward, consisting of 12 or 13 streets, and separated from the city by walls and ditches. On the western part of the town is a strong castle, built of freestone, where the Kubo, or secular emperor, resides when he comes to visit the Daïri. The streets are narrow, but regular, and always greatly crowded. The houses are like those at Osacca. Meaco is the principal manufacturing town of the empire, where every kind of manufacture is carried to the greatest perfection. Nearly every house has a shop, and the quantity of goods which they contain is astonishing; at the same time it is the centre of science and literature, and the principal place where books are printed; it is also the residence of the lord-chief-justice of the empire, who is invested by the emperor with supreme authority over all officers of government. The town is united by a wide canal to the river Yedogawa, which flows not far from its walls.

Kwano and Mia are two very considerable and thriving towns on the Gulf of Mia, each containing 2000 or 3000 houses, and carrying on a considerable trade with the neighbouring districts.

Yedo, the capital of the empire, is situated at the northern extremity of the gulf of the same name, in an extensive plain. According to the Japanese it is about ten miles long, seven wide, and is nearly 30 miles in circuit. All travellers agree that it is the largest and most populous town in the empire, but no one of them ventures to state the probable number of its inhabitants. A large river runs through the town and sends off a considerable arm, which encloses the imperial palace, or that of the Kubo, or secular emperor. There are several good bridges over the river. The principal is called Niponbas, or the Bridge of Japan, and from it the mile-stones are counted, which are erected along the principal roads that traverse the empire. Yedo is not so regularly built as Meaco, and the private houses do not differ from those of Osacca; but as the families of all the hereditary princes, lords, and noblemen are obliged to reside at the court the whole year round, the town contains a great number of fine palaces, though they are not above one story high. Rows of trees are planted along the numerous canals which traverse the town, to prevent the fires from spreading, which are very common. Yedo is not less famous for its manufactured goods than Meaco. The palace of the Kubo is built in the middle of the town. It consists of five palaces or castles, and some large gardens behind it, and is more than eight miles in circumference.

IV. The island of Yeso is very imperfectly known. On its western coast are high mountains. Its eastern and southern coast seem to be very thickly inhabited. Near the Strait of Sangar are two considerable towns, Kokodade and Matsmaï. The latter is the capital, and the residence of the governor.

The Japanese are not so strong as Europeans; but they are well made and have stout limbs. Their eyes show their Mongol origin, not being round, but oblong, small, and deeply sunk in the head. Their hair is black, thick, and shining, and their noses, although not flat, are rather thick and short. Their complexion is yellowish. They seem to resemble most the inhabitants of Corea, and the Aïnos on the island of Tarakai; but, according to appearances, they have derived their civilization from China. In manufacturing industry and in scientific knowledge they seem to be nearly equal to the Chinese, and in some articles the Japanese are superior. The Chinese themselves value the real Japan ware above their own inferior manufactures in lacker. Their manufactures in metals, silk, cotton, china, glass, and paper, and their cabinet-work, are highly esteemed. They also make excellent watches and clocks, and a late traveller (Meylan) mentions telescopes and thermometers. The fine arts are much admired, but the Japanese taste differs from ours, and is like that of the Chinese. The most antient religion is that of the Sinto, who was the offspring of the sun, the founder of the antient royal family and of the empire. But the greater part of the inhabitants have embraced Buddhism, which seems to have been introduced from Corea at a very remote epoch. Besides these two religions, a considerable number adhere to the doctrines of Confucius, the Chinese philosopher, and are called Syooto. In the seventeenth century the Roman Catholic religion was introduced by the Portuguese, and made great progress, but it was eradicated by a civil war and great persecutions, and entirely forbidden. All travellers who have been acquainted with both nations prefer the Japanese to the Chinese. They find them less cowardly, proud, cunning, and deceitful, and of a more manly and open character. In cleanliness and industry both nations are equal. The Japanese show a great desire for knowledge, and their institutions for instructing the lower classes seem not to be inferior to any on the globe. Indigence and pauperism are said to be almost unknown.

The government is despotic, but the emperor himself is considered as subject to the laws, which are of long standing and cannot easily be changed. Formerly, the Daïri Soma, the head of the Sinto religion, was the only sovereign of the empire; but as the public offices are hereditary, the chief general acquired gradually such an authority, that in 1585 he deprived the Daïri of his influence, leaving him only the supreme administration of ecclesiastical affairs; still however no enactment has legal force without having been previously sanctioned by the signature of the Daïri. The descendants of the chief general now govern the empire

under the title of Kubo Soma. The constitution of the Japanese empire is materially different from that of the Chinese in its hereditary nobility, dignitaries, and officers. The government of the provinces resembles in some respect the antient feudal system of Europe. The nobility, or hereditary governors of the provinces and districts, are called *Daimio*, or High-named, and *Siomio*, or Well-named. The first-mentioned govern the provinces, and the Siomio govern the districts. Six months of the year these noblemen are in their provinces to watch over their government, and six others they must pass at Yedo, but their families must remain in that town the whole year round as a security for the loyal conduct of the governors. According to Meylan, the population of the country is divided into eight classes—the princes or governors, the nobility, priests, military, civil officers, merchants, artisans, and labourers, by which we suppose agriculturists are meant. All these dignities, offices, and employments are hereditary; a circumstance which tends to keep society quiet, though it may also prevent some improvement.

The Japanese females have almost as much liberty as European females; most of them can play on a musical instrument which is like a guitar.

The inland trade is very considerable. The coasting trade is much favoured by the great number of small harbours, and the interior communication by well-planned and well-maintained roads, which are always thronged with carriages and people. Most of the roads are wide, and ornamented with lines of trees. The foreign commerce is limited to the Dutch and Chinese. The Dutch have a factory on the island of Desima, which is connected with the town of Nagasaki by a bridge. To prevent all communication with the inhabitants, it is planked on all sides, and has only two gates, one towards the town and the other towards the harbour. These gates are strictly guarded during the day, and locked at night In this inclosure are the storehouses, the hospital, and some houses built of wood and clay and covered with tiles. Only one ship is at present annually sent from the island of Java; it arrives in June and returns toward the end of the year. The Japanese export principally copper, camphor, and lacquered wood-work; with some china, silk-stuffs, rice, saki, and soy. The principal articles of importation are sugar, elephants' tusks, tin and lead, bar-iron, fine chintzes, Dutch cloths, shalloons, silks, cloves, and tortoiseshell; with some saffron, Venice treacle, Spanish liquorice, watches, spectacles, and looking-glasses. The Japanese copper does not reach the European market, being disposed of on the coast of Coromandel to great advantage.

The Chinese, like the Dutch, are shut up in a small island, but they are permitted to visit a temple in the town of Nagasaki; their trade is much more extensive. About seventy junks arrive annually from the ports of Amoy, Ningpo, and Shanghae, but as the Chinese have no factory they cannot remain during the winter in the harbour of Nagasaki. The Chinese junks arrive at three different times in summer

In the time of Kämpfer there was still some trade carried on with Corea and the Lew-Chew Islands, but this trade had ceased at the time of Thunberg (1775), and Siebold (1830) confirms this fact.

(*Ambassades Memorables*, &c., by Jacob van Meurs; Kämpfer's *History of Japan*: Charlevoix, *Histoire et Description générale du Japan*; Thunberg's *Travels in Europe, Africa, and Asia*; *Adventures of Captain Golownin*; Siebold's *Japan*; Extracts from Fischer and Meylan; *Journal of Education*, vols. vi., p. 370, x., p. 184.)

JAPANNING. Japanning is the art of producing a highly varnished surface on wood, metal, or other hard substance, sometimes of one colour only, but more commonly figured and ornamented. The process has received its name from that of the island of Japan, whence articles so varnished were first brought to Europe; though the manufacture is also extensively practised by the Chinese, Siamese, Burmese, and other nations of the extreme east of Asia, among whom it was suggested most probably by the possession of a tree, which affords with little preparation a beautiful varnish, exceedingly well adapted for the purpose, and which hardens better than those prepared in Europe.

The appearance of japanned work is as various as the taste and fancy of the artists employed in it. Sometimes it is a plain black or red, with a gilded or painted border; or it is an imitation of marble, of fine grained or rare wood, or of tortoiseshell; sometimes a drawing, in which high finish, brilliant colour, and showy patterns are more sought than good design; and occasionally fine copperplate engravings are applied to a japanned surface with good effect. In all cases the work is highly polished and varnished.

Japanning is applied to ladies' work-boxes and work-tables, to toilet-boxes, cabinets, tea-caddies, fire-screens, tea-trays, bread-baskets, snuffers and trays, candlesticks, and a variety of other articles. A good deal of common wood-painting is also called japanning, which differs from the more ordinary painter's work chiefly by using turpentine instead of oil to mix the colours with. Bedsteads, dressing-tables, wash-hand-stands, bed-room chairs, and similar articles of furniture are done in this way.

Three processes are usually required in japanning; laying the ground, painting, and finishing. In addition to these processes, whenever the matter to be japanned is not sufficiently smooth to receive the varnish, or when it is too soft or coarse, it is sometimes prepared or primed before any of the proper japanning processes are applied. It must here be observed, that almost every workman has his own peculiar modes of working, and his own receipts for making and mixing his varnishes; and that consequently only a very general idea can be given of the way in which the various operations are performed.

The preparatory mixture or priming is composed of size and chalk; the size is usually made of the ordinary carpenter's glue, which is well mixed up with as much chalk or whiting as will serve to give it a body sufficient to cover the colour and grain of the wood on which it is laid; it is put on with a brush like paint, and when perfectly dry, which will require a day or two, according to the state of the atmosphere, it must be brought to an even surface by rubbing with rushes, and then be smoothed by a wet rag. The best japanners disapprove of the use of priming, because its brittleness is very detrimental to the firmness of the varnishes laid over it; they use no substances which are of themselves unfit for receiving a varnish, or which they are unable to bring to a sufficiently smooth surface. For wood hard and fine enough to receive a varnish without priming, and for metals, paper, and leather, the only preparation necessary is a coat or two of varnish. In all these processes it is a rule to allow a day or two to intervene after every operation, that the work may be thoroughly dry.

When the work is prepared, the ground must be laid on; this is either all of one colour, or marbled, or done in imitation of tortoiseshell. The grounds are the ordinary pigments mixed with varnish, which are laid on smoothly with a brush: when thoroughly dry they are varnished, and afterwards polished by rubbing with a rag and tripoli or rotten stone; and, if the ground be white, with putty or starch and oil. The varnish used is either copal, or else it is composed of seed lac, or of gums animi and mastic; the lac varnish is considered by many workmen the best and hardest, but it is unfortunately too highly coloured for some of the more delicate grounds, to which it communicates a yellowish tinge; from this defect the gum varnish is free, but it is deficient in hardness; occasionally a mixture of the two is used, and some workmen prefer copal varnish to either gum or lac.

The mode of laying the grounds varies greatly; the old works on japanning are tediously minute in describing the various processes to be followed, detailing the number of times each coat should be laid on, and how long an interval should be allowed to elapse after each; and different proportions of colour and varnish are fixed as necessary to be used in each different operation. The mode now generally followed is to lay on one or two thick coats of colour mixed with varnish, then to varnish three or four times, and afterwards to dry the work thoroughly in a stove. The colours are flake-white or white-lead, Prussian-blue, vermillion, Indian-red, king's-yellow, verdigris, and lamp-black; intermediate tints are made by mixtures of these: an imitation of tortoiseshell is produced by vermillion, and a varnish of linseed-oil and umber. When a particularly gorgeous appearance is desired, the ground may be laid entirely in gold. This is produced by going over the work with japanner's gold size, which, when dry enough to bear touching with the finger, but still soft and clammy, is covered with gold-dust, applied on a piece of soft wash-leather. Any other metallic dust may be laid on in the same way. Many receipts are given for preparing the japanner's gold size, but nearly all agree in making linseed-oil and gum animi the

basis of the composition. A curious and very striking mode of laying the ground, called the dip, was formerly much practised; it was done by dropping small quantities of coloured varnish in a trough of water, over the surface of which it immediately spread in curious and often beautiful ramifications; into these the article was dipped; the colour was thus transferred to the work, and when dried was varnished and polished in the usual manner.

The work when thoroughly dry will now be ready for painting. The performer of this part of the process is rather an artist than a workman, though, as before stated, showyness and brilliancy are chiefly required in japanning, and bright colours with gold and bronze dust are largely employed. The colours are tempered with oil or varnish, and the metallic powders laid on with gold size. Copper-plate engravings or wood-cuts may also be executed in japan work; in this process the engraving is first printed off upon fine paper which has been previously prepared by a thick coat of isinglass or gum-water: when the print is perfectly dry, it is applied with its face downwards upon the japan ground covered with a thin coat of copal varnish; the paper is then moistened on the back with a sponge dipped in warm water, which in a few minutes dissolves the isinglass or gum, and the paper which is thus loosened is gently taken away, leaving the print on the work. Indian ink or other drawings upon paper may be transferred to the japanned ground in the same way. A more expeditious and very effectual mode of transferring an engraving is to print upon a smooth thick layer of a composition of glue, treacle, and whiting, which will receive an impression as perfectly as a sheet of paper: the composition, which is elastic and very flexible, may be immediately laid down upon the japanned surface, which will thus receive as goon an impression as if it could have been itself applied to the engraving.

In whatever manner the work has been painted or printed, or if all addition to the plain colour of the ground has been dispensed with, nothing now remains but the finishing. This is a very simple process: the workman chooses one of the before-named varnishes, and passes it over the work with a brush several times, until he judges the coating to be thick enough to bear the polish. It is an important precaution not to begin the varnishing until the preceding work is thoroughly dry, and to dry perfectly each coat before laying on a succeeding one. A hot stove is used in the best establishments to aid in drying the work. When thick enough, the varnish is polished by rubbing it with a rag dipped in finely-powdered tripoli or rotten-stone; towards the end of the operation a little oil is also applied to the rag, and the work is completed by rubbing with oil alone, to clear off the powder or any other impurity.

JAROSLAW. [YAROSLAW.]

JASHER, BOOK OF (ספר הישר), or 'the book of the upright,' is twice referred to in the Old Testament as a work of authority. (*Josh.* x. 13; 2 *Sam.* i. 18.) Many conjectures have been formed concerning the author and contents of this book; but we have no means of arriving at any satisfactory determination on the subject, since the work appears to have been lost before the time of the Babylonish captivity. Some critics have imagined it to be the same work as the book of Judges, which is evidently incorrect from the quotation in the book of Samuel; others, such as Bishop Lowth and Gesenius, have maintained that it was a collection of national songs.

In the year 1751, a printer of the name of Ilive published a pretended translation of the book of Jasher, which was said to have been translated from the original Hebrew by Alcuin of Britain. This work was republished at Bristol in 1829. An interesting account of this literary forgery is given in Horne's 'Introduction to the Scriptures,' vol. ii., part ii., pp. 132-138.

JASMINA'CEÆ, a natural order of Monopetalous exogens, deriving its name from the Jasminum, which forms one of its genera. It is one of the very few orders of that class with regular diandrous flowers, and is only to be mistaken for Oleaceæ, which have a valvate corolla, and which otherwise are scarcely different. Only four genera of this order have yet been discovered, the principal being Jasminum itself, which consists of a larger number of species, sometimes fragrant, sometimes scentless, erect or twining, inhabiting the hot or temperate regions of Europe, Africa, and Asia, including New Holland, but hardly known in America. The order is characterized by having opposite or alternate, simple or compound, exstipulate leaves; monopetalous flowers, the segments of whose corolla are imbricated, and seldom correspond with those of the calyx: 2 stamens, and a superior 2-celled few-seeded ovary. The species are chiefly valued for their fragrance; a few species have been regarded as bitter and astringent.

Jasminum officinale

1 a longitudinal section of the corolla, 2, a longitudinal section of the ovary and calyx.

JASON. [ARGONAUTS.]

JASON. [THESSALY.]

JASPER. [SILICIUM.]

JASSA, a genus of Amphipodous Crustaceans, established by Dr. Leach.

The general characters resemble those of *Corophium*, Latr.; but differ from them as well as from those of *Podocerus*, Leach, in the considerable size of the *hands* of the four first feet, which are oval; those of the second pair being the greatest, and armed with teeth more or less numerous on the internal border. *Eyes* not projecting.

Dr. Leach records two species, one, *Jassa pulchella*, from the south coast of Cornwall, where it was found in the middle of sea-weed; the other, *Jassa pelagica*, found near the Bell Rock, Scotland.

JASSY. [MOLDAVIA.]

JATROPHA, a genus of plants inhabiting the tropical parts of the world and belonging to the natural order Euphorbiaceæ. It contains among its numerous species the Jatropha or Jampha Manihot, a Brazilian and Guayana plant, whose fæcula forms a well known nutritious substance, called *Cassava*, when prepared in one manner, and *Tapioca* in another state. This secretion is analogous to the meal in the Potato, the Yam, and the Batatas, but it is mixed naturally with a highly dangerous juice, which it is necessary to remove by washing and evaporating before the fæcula is fit for food. When properly prepared, this substance is extremely nutritious, and forms the principal part of the vegetable diet of the poorer classes in South America.

JAUM GHAUT. [HINDUSTAN, p. 212.]

JAUNDICE (from *jaune*, yellow) is the name given to those diseases in which the excretion of the bile being prevented, it is retained in the blood, or reabsorbed, and being diffused throughout the system, gives a yellow colour to the skin, and all the other tissues and secretions.

The name is however very indefinite, because the cases in which the separation of the bile is prevented are various. Everything, for example, which obstructs the main trunk of the bile-ducts, as gall-stones [CALCULUS, BILIARY] or other foreign bodies filling its canal, certain morbid alterations of the liver or duodenum [INTESTINES], or of the duct itself, tumours and enlargements of adjacent organs, will alike mechanically produce jaundice, though their other symptoms differ widely. Again, it is often a symptom of inflammation of the liver, as especially in yellow fever, and of inflammation of the duodenum. But the most frequent cases are those which do not appear to be the consequence of any organic disease, but are accompanied by the

symptoms of general disorder of the digestive organs, as nausea or vomiting, thirst, and loss of appetite, confined or irregular condition of the bowels, headache, and general uneasiness. These cases generally come on suddenly, as a sequel of common diarrhœa, or in the dyspeptic and those of a sedentary habit, or whose bowels have been long inactive. It is often difficult to say what prevents the excretion of the bile; sometimes it is separated from the blood in too viscid a form; sometimes mucus appears to obstruct the duct; in many cases there is probably spasm of the duct, as in those which occur after violent fits of anger or other mental affection; and in some a larger quantity of bile appears to be formed than can be conveyed away with proportionate rapidity.

It is impossible that any one mode of treatment should be adopted for a symptom depending on such varied causes. Where the obstruction is mechanical, the jaundice is of course curable only by the removal of its evident cause; and in inflammation of the liver it is but a symptom of a more important disease, to which the treatment must be directed. In the more common cases, which, as distinguished from these, are sometimes called functional, the treatment should consist chiefly of small doses of mercury, and active purgatives containing calomel or neutral salts. Warm baths and opium should be used, if there be any spasmodic pain of the right side: and leeches or bleeding, if any inflammatory pain or tenderness be felt. A mild diet and the avoidance of all stimulant drinks or food should be carefully enjoined.

JAVA, one of the Greater Sunda Islands, the third in extent, but the first in importance, is situated between 5° 52′ and 8° 4′ S. lat., and between 105° 11′ and 114° 13′ E. long. On the south and west it is bounded by the Indian Ocean. The north-western corner of the island forms with the most southern extremity of the island of Sumatra the Straits of Sunda, which at one place are only fourteen miles across, and unite the Indian Ocean with the Java Sea. The last-mentioned part of the Indian Ocean washes the northern shores of Java, and at the south-eastern extremity of the island it is again united with the ocean by the Strait of Bali, which in the narrowest part is only two miles wide. The length of Java from Java Head on the west to East Point (Oost Hoek) is 666 miles; its breadth varies from 56 to 135 miles. The area is estimated at 50,000 square miles, or about that of England.

The island of Madura is commonly included in Java, from the north-eastern part of which it is divided by the Strait of Madura, which in one part is only one mile broad. Madura is 91 miles long, and 31 miles wide in the widest part.

Surface and Soil.—The southern coast in its whole extent is high and steep, rising in many places perpendicularly to an elevation of 80 or 100 feet, and in some places much higher. It runs in a continuous line, with few indentations, and those not deep. Consequently there are few places which have good anchorage, and as it is exposed to the open ocean, and to a high swell or surf, it is not much visited by shipping. Still a few good harbours occur; the best are Chelachap, about 109° E. long., and Pachitan, about 111° E. long.

The hilly country which is contiguous to the southern coast rises rapidly as we advance inland, and probably attains towards the middle of the island a mean elevation of more than 1000 feet, where it extends in elevated plains with an uneven or hilly surface. This hilly country does not extend over the whole breadth of the island, except at the western extremity as far east as Bantam, and in the peninsula, which comprehends the most eastern districts east of 112° 30′. This elevated region is traversed by numerous ridges of hills, probably rising to 2000 or 2500 feet above the sea-level, and running mostly in the direction of the island's length. On these ridges a considerable number of peaks rise to a great elevation. It is stated by Raffles that there are thirty-eight of such peaks. They have all a broad base, and gradually diminish in size to the summit, which has always the form of a cone. They are all volcanic. Indications and products of their former eruptions are numerous and unequivocal. The craters of several are completely obliterated; those of others contain small apertures which continually discharge vapours and smoke. Many of them have had eruptions during the present century, which have caused great loss of property and life.

The highest and most remarkable of these volcanic peaks are the Pangerango, south of Buitenzorg, more than 8000 feet high; Mount Gede, south-east of the former, rising to 9888 feet; the Dshirmai, south-south-west of Cheribon, more than 8000 feet high; the Gede Tegal, near 109° long., which probably attains between 11,000 and 12,000 feet; and Mounts Sindoro and Sumbing, called the Two Brothers, near 110° long. Three large volcanoes, called Ung'árang, Merbidu, and Merápá, lie in a direction almost south and north across the hilly region near 110° 30′ E. long. Near the eastern peninsula is the Arjúna, 10,614 feet high, and south-east of it, not far from the Indian Ocean, the Smeero, or Semiru, probably the most elevated of these peaks. At the north-eastern extremity of the island near Cape Sedano is the elevated volcano of Telágawurung.

The hilly region contains some extensive plains and valleys of great fertility, enclosed by the ridges of hills which connect the peaks. The largest of these elevated plains is that of Bandung, which seems to occupy nearly the whole tract from Mount Gede on the west to Mount Gede Tegal on the east. It is of great fertility, though somewhat inferior to the two valleys which lie contiguous to it on the east—the Vale of Banyumas, traversed by the beautiful river of Serayu, and the Vale of Kedù, on the banks of the river Elo. East of the last-mentioned vale is the elevated plain of Solo, which extends round the town of Sura-kerta, and exhibits a great degree of fertility. The elevated plain of Kediri, traversed by 112° long., is equally extensive and fertile. The eastern peninsula, whose surface is mostly occupied by peaks and high ridges connecting them, has only narrow and close valleys.

The elevated and hilly region terminates to the north in rather a steep slope, and between it and the Java Sea extends a flat country which descends imperceptibly from the foot of the hills to the very shores, where it terminates in some places in swamps. This low tract, which is mostly alluvial, is widest towards the west, and occupies nearly one-fourth of the width of the island, or about 40 miles, between Bantam on the west and Cheribon on the east. Between Cheribon and Samárang it is hardly more than 10 miles wide. This portion of the low lands is not equal in fertility to the inland districts. In Samárang are the flats of Demák, which extend between the elevated region and the mountains of Japára; they were once an extensive swamp, and are hardly inferior in fertility to any part of the island. East of these flats and between the same mountains are the low lands of Jipang and Surabáya, which terminate on the strait and gulf of Madura with the delta of the Surabaya river; the delta is also distinguished by its fertility. The low lands of Demak, Jipang, and Surabaya divide the mountains of Japara and some lower ridges from the elevated regions. The mountains of Japara, which contain a peak of considerable elevation, occupy the peninsula of Japara, on which the low coast-tract is very narrow. This isolated mountain system is separated by a deep valley, covered with alluvial soil, from a low ridge which occupies the whole tract of the coast between Cape Lerang and Cape Panha, and perhaps 10 or 15 miles inland.

The northern coast is lined by numerous small islands, and is marked by many projecting points and headlands. Accordingly the harbours are numerous. But the whole coastline affords anchorage at nearly all seasons of the year, and vessels of any burden can approach all the principal stations at a convenient distance for the exchange of their merchandise. The sea being generally smooth and the weather moderate, the native vessels and small craft always find sufficient shelter at the change of the monsoon by running under some island, or passing up the rivers, which though in general difficult of entrance on account of their bars, are for the most part navigable for such vessels as far up as the maritime towns.

The soil of Java is generally deep and rich. The best soils are the alluvial soils along the beds of the rivers, and on the slopes of the largest mountains; the worst are on the declivities of the lower ranges. But though there are these varieties, the general character of the soil is that of extraordinary fertility. The eastern districts however are superior to the western. The neighbouring countries, especially Sumatra and the Malayan peninsula, cannot be compared with Java in this respect. The best soils annually produce two crops without manure, and even the poorest remunerate the labour of the husbandman.

Rivers.—Java is watered by numerous rivers, but few of them have a considerable course on account of the compa-

rative narrowness of the island. There may probably be fifty streams, which in the wet season bear down rafts loaded with timber and other rough produce of the country. Five or six are navigable at all times to a distance of some miles from the coast. The rest, in number many hundreds, if not thousands, are used to irrigate the fields.

The Solo River rises with many branches near the southern coast in the mountains of Damong, and runs northward to Sura-kerta, where it is a stream of considerable depth and breadth; it afterwards turns to the east, and at Awi it is joined by the Madion. From this point to its mouth its course is calm, regular, and steady. It enters the Strait of Madura by two mouths at Gresek and Sidayu. From Sura-kerta to Gresek it is stated to run 356 miles, measured along the windings of the river, though in a straight line the distance is only 140 miles. In this part of its course there is no impediment to navigation. During the rainy season it is navigated by boats of considerable size, and except in August, September, and October, and in seasons uncommonly dry, it floats down boats of middling or small size during the whole year, from a considerable distance above Sura-kerta.

The Kediri or Surabaya River forms nearly a circle, and its source and mouth are situated almost in the same latitude. It rises at the base of the volcano Arjúna, winds round Mount Kawi, and is a large river at Kediri. From this place its course is no longer interrupted by any impediment, and it bears boats of a very considerable size to its outlets in the Strait of Madura. Its mouths are five in number, and they include a pretty extensive and very fertile delta.

There are no lakes in Java, but some low lands are converted into temporary swamps during the rains. Two of these swamps are of considerable extent; one called the Binnen See, at the foot of the Japára Mountains, and another not far from Samárang.

Climate.—In Java, as in other countries between the tropics, the year is divided into a wet and a dry season, and these seasons depend on the periodical winds. The setting-in of these winds is not determined within a few weeks; but generally the westerly winds, which are always attended with rain, commence in October, become more steady in November and December, and gradually abate, till in March or April they are succeeded by the easterly winds and fair weather, which continue for the remaining half year. The heaviest rains fall in December and January, and the driest weather is in July and August. Yet even during the rainy season there are many days without showers; and although the rains sometimes continue for several days, and frequently fall in torrents, they are not marked by that decided character, either of permanence or violence, which distinguishes the periodical rains on the continent of India. The same may be said of the dry season. Even in July and August the atmosphere is refreshed by occasional showers. The degree of heat varies considerably in the low lands and the hilly region. On the low northern shores at Batavia, Samárang, and Surabaya, the mean annual heat is 78°; but in the dry season the thermometer rises as high as 90°, and even higher about three o'clock in the afternoon. Usually however it ranges between 70° and 74° in the evenings and mornings, and attains 83° or 85° in the afternoon. The elevation of the interior offers the rare advantage that, from the sea-shore to the top of the mountains, there is almost, from one end of the island to the other, a regular diminution of temperature, at the rate of two or three degrees of Fahrenheit for every ten miles. The mean heat on the elevated plains probably does not exceed 66° or 68°, and the thermometer rarely rises there to 72°. On the summits of the peaks it sinks below the freezing-point: ice as thick as a Spanish dollar has been found, and hoar-frost, called by the natives 'the poisonous dew,' has been observed on the trees and vegetation of the higher regions. Hurricanes are unknown. With the exception of a few days at the change of the monsoons, or when the westerly winds are at their height, vessels of any description may ride in safety in most of the bays along the northern coast; and on shore the wind is never so violent as to do damage. Thunder-storms are frequent and destructive. Earthquakes are common in the vicinity of the volcanoes, but the European towns have not suffered from them. Java was formerly considered one of the most unhealthy countries of the globe, and this character is certainly due to the greatest portion of the low coast along the Java Sea; but on examination it has been found that by far the greatest part of the island, in point of salubrity, is equal, if not superior, to any other tropical country.

Productions; Vegetables.—Though not equal to the Hindus in agriculture, the Javanese are far superior to their immediate neighbours of the other islands. They are well acquainted with the cultivation of rice and other grains on the slopes of the mountains and hills, which are formed into terraces. They know likewise the advantages of a careful irrigation, and in some parts they grow, in the wet part of the year, a crop of rice, and in the dry part some species of pulse, farinaceous root, or cotton. In the richer lands however it is usual to take from them without interruption a double harvest during every twelve months. Rice is here, as in India, the principal object of the husbandman, and its produce determines the value of the land. Maize, or Indian corn, is not very extensively grown, but of late years its cultivation has much increased. In rich lands it returns four or five hundred-fold; and even in poor lands it yields sixty or seventy fold. Wheat has been introduced by the Dutch, and is cultivated on the more elevated lands, but its produce is in small quantity and of inferior quality. Millet is grown in some places on a limited scale. Among the many esculent roots cultivated the principal are the yam, the sweet potato, the Java potato, arrowroot, and the common potato. The last is only grown in the more elevated and colder districts, where also artichokes, cabbages, and peas succeed, but carrots not so well. The Javanese also cultivate cucumbers, onions, and capsicums. As they do not use butter, they consume a great quantity of different kinds of oil, made from the fruit of the cocoa-nut tree, the ground-nut (*Arachis hypogæa*), the Palma Christi, and the Sesamum, all of which are cultivated with considerable care. They also plant the Areca palm, on account of its nuts, and the Gomuto palm, partly on account of the toddy, or palm-wine, obtained from it, and partly on account of a substance resembling black horse-hair, which forms between the trunk and branches, and is used for every kind of cordage, domestic and naval: of late years it has been much used in European vessels. From its pith a kind of flour may be made, not unlike sago, but of inferior quality. There are also extensive plantations of the betel and of tobacco: and of fruit trees especially the following are cultivated: the plantain or banana (*Musa Paradisiaca*), the bread-fruit tree (*Artocarpus incisa*), the jack-tree (*Artocarpus integrifolia*), the mangustin (*Garcinia mangostana*), the durian (*Durio Zibethinus*), the mango (*Mangifera Indica*), different kinds of the orange and lemon tribe, especially the shaddock (*Citrus decumana*), the pine apple (*Bromelia ananas*), the Jamba (*Eugenia*), the Guava (*Psidium pomiferum*), the papaya (*Carica papaja*), the custard-apple (*Anona squamosa* and *reticulata*), and the cashew-nut (*Anacardium occidentale*). Besides these the pomegranate (*Punica granatum*) and the tamarind (*Tamarindus Indica*) are grown. European fruit-trees have not succeeded: the grape is cultivated in several places; but it is seldom of a good quality. The culture of the pear, the apple, and the peach has been still more unsuccessful.

The plants which afford articles for foreign exportation are the coffee-tree, the sugar-cane, the pepper-vine (*Piper nigrum*), the cardamom (*Amomum cardamomum*), ginger, the sandal-tree (*Santalum*), and the cotton-plant. The forests, which cover a part of the elevated region, especially in the eastern districts, contain a great number of teak-trees, whose timber is considered inferior to that of Malabar, but superior to that of the Birman empire. Ebony-wood is also found, and among their creeping plants are the rattan (*Calamus Rotang*, L.), and two species of caoutchouc trees.

As dye-stuffs there are cultivated indigo (*Indigofera tinctoria*), safflower (*Carthamus tinctorius*), arnotto (*Bixa orellana*), and turmeric (*Curcuma longa*, L.). Several fruit-trees produce dye-woods, as the sappan (*Cæsalpinia sappan*), the mangkuda (*Morinda*), and the ubar, similar to the logwood of Honduras.

There are two trees in this island from which poison is extracted, the *antjar* and the *chetik*. The antjar, also called the *Bopon upas* (or the poisonous tree), is a high forest-tree, from whose outer bark poison is extracted in the form of a milk-white sap. But its exhalations are not poisonous, nor is it, as was formerly supposed, hurtful to plants around it, creepers and parasitical plants being found winding in abundance about its trunks and branches. (Crawfurd.)

Animals.—There are no elephants, camels, or asses. The horses are of a small breed, but strong, fleet, and well made. Buffaloes are numerous, and of greater use in agriculture than any other animal. Black cattle are common, but much more so in the central and eastern districts than in the western. Goats are abundant, but sheep are scarce; both are of small size. The hog is reared chiefly by the Chinese.

Of beasts of prey there are the tiger, the leopard, the tiger-cat, and the jackal. Other wild animals are the rhinoceros, the wild Java ox, the wild hog, and the stag, as Raffles calls it, which is perhaps the axis deer.

Of domestic birds there are turkeys, geese near the settlements of the Europeans, ducks, fowls, and pigeons. Among the wild birds the most remarkable is the *hirundo esculenta*, whose nests are eaten, and exported in large quantities to the Chinese market. They are called Salanganests.

The cayman is abundant in the rivers of Java, but, according to Raffles, the animal much more resembles the crocodile of Egypt than the alligator of America. This crocodile is mentioned by Thunberg and by Mandelslo, the latter of whom says that it was eaten by the natives. Of serpents there are said to be several poisonous varieties. Turtle and fish are abundant. Honey and wax are also obtained. Silkworms were once introduced by the Dutch, but this branch of industry did not extend among the natives.

Minerals.—Few minerals are known to exist in Java Iron is said to be found in small quantity, and indications of gold have been observed at several places. Salt is made of sea-water in some parts of the northern coast. Saltpetre is extracted from the earth of some caves, and sulphur is found near the volcanoes.

Political Divisions, Towns, &c.—The greatest part of the island is in possession of the Dutch. The districts situated on both extremities of the island, as well as the whole of the northern coast, are immediately subject to them. But the southern coast and the adjacent countries, between 108° 30′ and 112° 20′ E. long, with the exception of the small district of Pachitan, which has been recently ceded to the European government, is subject to two native princes, the Susuhúnan, or emperor, and the sultan. Their dominions extend more than 250 miles along the southern coast, and form about one-fourth of the whole island.

1. The Dutch possessions are divided into 17 provinces. The country west of 108° 30′ comprehends five of them, Bantam, Batavia, Buitenzorg, the Preanger districts, and Cheribon. The low and alluvial parts along the coast are of considerable fertility, but large tracts in the mountain-ranges still remain in a state of nature, and where the ground has been cleared of forests they are now overgrown with long and rank grass. The elevated plain of Bandung however is well cultivated and peopled. The Preanger districts are governed by native hereditary princes, who pay a tribute to the Dutch. The most considerable and remarkable towns in this country are on or near the northern shores Sirang, or Ceram, where the governor of Bantam resides, is a thriving place some miles inland, and distant from the antient town of Bantam, which has been abandoned. Batavia, which once had a population of 160,000 souls, contained in 1834 not more than 53,861 inhabitants, having been partly abandoned on account of its unhealthiness. [BATAVIA.] But its suburbs, situated at some distance and on a higher level, have received a great part of the population. Of these suburbs Molenvliet is built in the Dutch fashion along a wide canal, and is mostly inhabited by Europeans; Ryswick, the seat of the general governor, contains a fine palace and beautiful square, called the Royal Place; Weltefreden, is the central point of the military force, with extensive barracks; and Noordwyck is inhabited by the merchants and people in trade. Cheribon is a thriving town, with a good roadstead and 10,000 inhabitants; it contains a beautiful mosque. In the interior of the country is Buitenzorg, a thriving and well-built village, 40 miles from Batavia and at the foot of the volcano of Pangerango. It contains the summer palace of the governor-general and many fine country-houses. A navigable canal unites it to the harbour of Batavia. The most considerable town in the Preanger districts is Chanjur.

The Dutch possessions east of 108° 30′ to the Strait of Madura contain the nine provinces of Tegal and Brebes, Pakalongan, Kedú, Samárang, Japara, Rembang, Gresek, and Surabaya. They constitute the most fertile part of the Dutch dominions, and contain the Vale of Kedú, the flats of Demák, and the Plain of Surabaya. The chief towns from west to east are the following:—Samárang, with more than 30,000 inhabitants, has an extensive commerce. Foreign vessels are permitted to trade to it. There is a military academy. Rembang has 8000 inhabitants and some trade. Surabaya is situated on the Straits of Madura, which form an excellent and spacious harbour with good anchorage, and secure against the violence of the sea and wind. It is the most populous and thriving town of Java, and its population exceeded 80,000 souls in 1815. Its harbour is open to foreign vessels. In the interior, in the Vale of Kedú, are the extensive and admired ruins of the temples of Boro Bodor.

The eastern peninsula, which extends to the Strait of Bali, is less fertile than any part of the island, being almost entirely occupied by mountains. It contains three provinces, Passaruan, Besuki, and Banyuwangi, of which the last is noted for its coffee, which is stated to be superior to that of Mocha, and for the great quantity of sulphur which abounds here. Passaruan is a small town on the sea-coast.

2. The dominions of the Susuhúnan, which contain a population of nearly one million, consist of two separate tracts. The largest lies between 108° 30′ and 110° E. long., and contains the fertile vale of Banyumas, with the town of the same name, which has 8000 inhabitants. From this the smaller portion is separated by the Vale of Kedú and some territories of the Sultan. It lies in the interior of the island, between 110° 30′ and 111° 20′ E. long., and contains the residence of the Susuhúnan, called Sura-kerta, on the Solo River, which has a population of 105,000 souls.

3. The territories of the Sultan extend between 110° and 112° 20′ E long., and contain nearly 700,000 inhabitants. In their eastern districts is the fertile plain of Kediri. The capital is Yugya-kerta, a town with 90,000 inhabitants. In its vicinity are the ruins of Brambanan, called Chandi Sewu, or the Thousand Temples. [BRAMBANAN.]

Inhabitants.—The natives of Java belong to the widely spread race of the Malays. They are short, thick-set, and robust. Crawfurd thinks that their medium height is about four inches less than the average stature of Europeans. Their lower limbs are rather large and heavy, but not ill formed; their arms are rather fleshy than muscular. The face is of a round form, the mouth wide, the teeth remarkably fine, the chin rather of a square form, the cheek-bones are high and the cheek consequently rather hollow. The nose is short and small, never prominent, but never flat; the eyes are small and always black. The complexion is generally brown, and darker than in the neighbouring islands. The hair is long, lank, harsh, and always black. They have very little beard. The Javanese are Mohammedans, but the creed of the Arabian prophet, which was introduced among them in the fourteenth century, has been much modified by the doctrines and ceremonies of Buddhism. Three different dialects of the Malay language are spoken on the island, but they have also an antient sacred language called Kawi, which contains a great number of Sanscrit words. The Javanese have a native literature, which however is not rich. They have also translations from the Sanscrit and Arabic; the latter are small in number and solely on subjects of religion and jurisprudence. In civilization the Javanese are much superior to all other nations who inhabit the Indian Archipelago. This is evidently shown by the state of their agriculture, though it cannot be compared with that of the Hindus or Chinese. In the art of fishing they are very expert, like all the other nations of this part of Asia. They do not eat their fish in a fresh state; it is almost always salted or dried. A peculiar preparation, called by the Malays *blachang*, and by the Javanese *trasi*, is a mass composed of small fish, chiefly prawns, which is fermented and dried in the sun. It is used as a universal sauce, more generally than soy with the Japanese; and as soon as Europeans have overcome their repugnance to it, they become as partial to it as the natives. In no kind of manufacture are the Javanese distinguished, except in working gold. Their cotton-cloth is coarse, but of a substantial and durable texture; a small quantity is exported. The raw silk, imported from China, is manufactured into a rich thick tissue, more distinguished how ever by the quantity of material which it contains, than by the beauty of the workmanship. The Javanese show also considerable skill in the construction of their vessels and boats, of which there is a great variety.

The whole population of Java in 1815 consisted of 4,520,829 natives, and about 100,000 foreigners settled on the island. The foreigners are Chinese, Malays, Hindus, Arabian merchants, and slaves brought by the Europeans and Chinese from Bali and Celebes.

Commerce.—Java is extremely well adapted for an extensive commerce. The island itself is rich in productions, and its northern coasts, which are accessible to vessels all the year round, lie opposite the richest countries of Asia Besides this, the Dutch government has made it the centre of all the trade which Holland carries on with its extensive settlements in the Indian Archipelago. All the goods destined for consumption in the Moluccas, Celebes, Borneo, and the eastern coast of Sumatra, are sent to Batavia, and forwarded thence to the places of consumption. The exports of these countries, intended for the European and American market, are likewise sent to Java and thence to Europe. The trade of the island was always open to the independent Asiatic nations, and since its re-occupation by the Dutch the vessels of all European nations are admitted into the ports of Batavia, Samárang, and Surabáya.

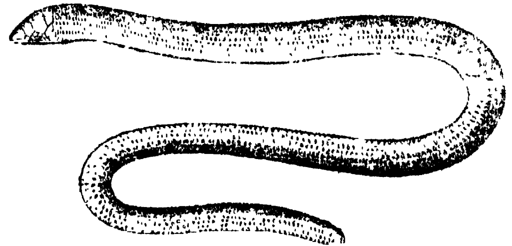
The Dutch and other Europeans and the North Americans export from Java chiefly coffee, sugar, rice, pepper, and arrack; minor articles are, long pepper, cubeb pepper, ginger, turmeric, cajeput oil, tamarinds from Madura, sapan, rattans, and some hides and horns of buffaloes and oxen; also vessels built of teak, and teak timber. The imports are cotton fabrics, especially chintzes, white cottons, handkerchiefs, and velvets; woollen broad-cloth; iron, unwrought, Swedish and British; Swedish steel; some cutlery, nails, and small anchors; wrought copper, the unwrought copper being imported from Japan; some fire-arms and ammunition; glassware and earthenware; opium from Malwa and Turkey.

The Chinese chiefly visit the harbours of Batavia and Samárang, and their junks depart from the harbours of the provinces of Quantun, or Canton, Fokian, and Chekiang especially Canton, Amoy, Changhu, Tyanchu, Ningpo and Shanghae. Their importations, in the order of value, are black tea, coarse porcelain, wrought iron, principally in the form of pans for the sugar-houses, and other culinary vessels, cotton-cloth, raw and wrought silk, especially satins of various colours, with a few velvets and brocades, brass ware, paper, books, paint, shoes, fans, umbrellas, and toys. They take in return black pepper, long pepper, sandal wood, mostly imported from the island of Timor, betel-nut, bees'-wax, cotton, edible birds' nests, sharks' fins, rhinoceros horns and hides, ox and buffalo hides and horns, European woollens and cottons.

The inhabitants of the other islands of the Indian Archipelago carry on an active commerce with Java by means of the Bugis, or inhabitants of Boni, in Celebes. These active navigators and adventurers leave their country in the beginning of the eastern monsoon, and carry on a trading voyage as they proceed westward, until they reach the limit of their navigation at Malacca, Penang, and Achin, and prepare to return with the change of the monsoon. The commodities which they export from their own country and the islands which they visit before they arrive at Java are, the excellent and durable cotton-cloth of their native country, gold-dust, nutmegs, Spanish dollars, camphor, frankincense, and tortoiseshell. They take in return birds' nests, European and Indian cotton goods, unwrought iron, salt, rice, different kinds of pulse, and tobacco.

The inhabitants of Coromandel and Malabar bring to Java blue cotton-cloth, cotton chintzes, and tobacco; and take in return betel-nut, bees'-wax, black pepper, nutmegs, and mace, brought from the Moluccas, ivory and damar from Borneo and Sumatra, and tin from Banca.

A few vessels from Mocha in Arabia annually visit Java. They first go to Malabar and import cotton-cloths, fruits, and bullion: and take in return cloves and nutmeg, black pepper, betel-nut, rice, and sugar.



It is stated, that in 1825 the imports into Java amounted to about 1,140,000*l.*, and the exports to about 1,430,000*l.* The Dutch imported to the amount of about 200,000*l.*, and exported to the amount of about 688,000*l.* The British imported, partly from Bengal, to the amount of 155,000*l.*, and exported to the amount of 36,000*l.* Hamburg imported to the amount of 11,000*l.* The French imported to the amount of 14,000*l.*, and exported to the amount of 16,000*l.* Sweden imported to the amount of 1000*l.*, and exported to the amount of 9000*l.* The North Americans imported to the amount of 190,000*l.*, and exported to the amount of 34,400*l.* Merchandise to the amount of 4000*l.* was sent to Mocha in Arabia. The exports to China were estimated at 113,600*l.*, and the imports at a similar sum. From Java were sent to the other islands of the Indian Archipelago goods amounting to 379,000*l.*, and from these islands were imported others amounting to 344,000*l.*

History.—The Portuguese reached Java in 1511, and soon after began to form small settlements. The Dutch established themselves at Bantam in 1595, and in 1602 the English erected a factory at the same place, which was the first possession of the English in the East Indies. But the English as well as the Portuguese were soon obliged to give way to the Dutch, who built the town of Batavia, and by degrees enlarged their dominion, until they succeeded, about the middle of the last century, in dividing the empire of the Susuhúnan into two parts, and appropriating the greater portion of it to themselves. The two sovereigns became at the same time dependent on the Dutch government, and have since been obliged to sell to them, at fixed and low prices, considerable quantities of rice, pepper, sugar, and coffee. The Dutch also claim the right of confirming the successors of the sultans. When Holland was united to the empire of Bonaparte, the British took possession of the island in 1811, but restored it to the Dutch after the fall of Bonaparte in 1816.

(Stavorinus, *Voyages to the East Indies*: Raffles's *History of Java*: Crawfurd's *History of the Indian Archipelago*; Count Hogendorp's *Coup d'Œil sur Java, &c.*: *Description Géogr., Histor. et Commerciale, de Java et des autres Isles de l'Archipel Indien.*; *Ueber die Kawi Sprache auf der Insel Java, &c.*, von W. von Humboldt, Berlin, 1836.)

JAVELIN SNAKE. [ACONTIAS; BLIND-WORM, vol. iv., p. 529.]

The cut which illustrates *Acontias* appears to have been taken from Cuvier's reference (*Règne Animal*) to Seba, ii., xxi., 1, which is erroneous. In the plate of Seba quoted, No. 4 may pass for an *Acontias*, but No. 1 represents a totally different form.

Acontias Meleagris.

JAXT (now often written Jagst), one of the four circles into which the kingdom of Würtemberg is divided. It borders on the north-west on Baden, and on the north and east on Bavaria. It has an area of 2104 square miles, and a population of 355,691 inhabitants It is divided into 14 high bailiwicks. The chief town is Ellwangen. The principal rivers are the Jaxt, from which it has its name, the Kocher, and the Rems. The greater part of the possessions of the princes of the House of Hohenlohe is situated in this circle. This ancient House is descended from Eberhard, duke of Franconia, who died in 918, and was brother to King Conrad, and is named from the castle of Hohenlohe (Hollach, Hollo), the ruins of which are still to be seen at the village of Hollach near Uffenheim in Bavaria. The princes of Hohenlohe lost their sovereign rights on the dissolution of the German Empire and the formation of the Rhenish Confederation, and were declared vassals of the kings of Würtemberg and Bavaria. The House now consists of two principal lines, Hohenlohe Neuenstein and Hohenlohe Waldenburg. The first, which is Protestant, is divided into three branches: H. Langenburg, with a territory of 95 square miles and 16,800 inhabitants; 2. H. Oeringen (formerly Ingelfingen), with a territory of 130 square miles and 24,870 inh.; 3. H. Langenburg-Kirchberg, with a territory of 84 square miles and 15,400 inh. The second main line, which is of the Roman Catholic religion is likewise divided into three branches: Hohenlohe Waldenburg and Bartenstein, with a territory of 148 square miles and 23,000 inh.; 2. H. Bartenstein-Jaxtberg, with a territory of 135 square miles and 10,800 inh.: 3. H. Waldenburg-Schillingsfurst, with a territory of 125 square miles and 17,500 inhabitants

JAY. [CORVIDÆ, vol. viii., p. 69.]

JAYADE'VA, a celebrated Hindu poet. We possess hardly any particulars respecting the circumstances of his life. It appears from a passage in his poems that he was born at Kenduli; but the position of this town is very doubtful. Some commentators place it in Kalinga, others in Burdwan; but according to the popular tradition of the Vaishnavas, it was situate near the Ganges. (Wilson, in *As. Res.* xvi. 52.) If the verse at the end of the 'Gîta Govinda' is genuine, the name of Jayadeva's father was Bhojadeva, and that of his mother Râmâdevî. According to Sir William Jones, Jayadeva lived before Câlidâsâ (*As. Res.* iii. 183); but this is exceedingly improbable, both from the artificial construction of the verse and the whole tenor of the poem. Professor Wilson places Jayadeva in the 15th century of the Christian æra (*As. Res.* xvi. 37); but Lassen, with greater probability, supposes that he lived in the middle of the 12th century. (*Prolegomena* to the 'Gîta Govinda,' pp. iv. v.)

The only poem by Jayadeva which is extant is entitled 'Gîta Govinda;' that is, 'the poem in honour of Govinda,' one of the names of Krishna, the eighth *avatar*, or incarnation, of Vishnu. The poem is a kind of pastoral drama, in which the loves of Krishna and Râdha are described in a glowing and voluptuous manner. This poem has always been greatly admired among the Hindus; and the majority of Hindu commentators contend that it is not to be understood in a literal, but in a figurative and allegorical sense, and that the loves of Krishna and Râdha describe the 'reciprocal attraction between the divine goodness and the human soul.' Among the Europeans, Sir William Jones and Colebrooke admit this allegorical mode of interpretation (*As. Res.* iii. 183; x. 419); but we are inclined to believe that the 'Gîta Govinda,' like the poems of Hafiz, is in reality what it professes to be, merely an amatory poem; and that the allegorical mode of interpretation is the invention of commentators and scholiasts. The question has been very ably discussed by Lassen in his Prolegomena.

An English translation of the 'Gîta Govinda' was published by Sir William Jones in the third volume of the *As. Res.* The original text was printed very inaccurately at Calcutta in 1808; a new and very accurate edition, with notes, and a Latin translation, edited by Lassen, was published at Bonn, 1836.

JEAN I., a posthumous son of Louis X. *Hutin*, was born in 1316, and lived only eight days, but is numbered in the chronological order of kings. At his death his uncle and regent Philippe le Long assumed the title of Philippe V.

JEAN II., son of Philippe de Valois and of Jeanne of Burgundy, ascended the throne upon his father's death in 1350. At the beginning of his reign he caused Raoul, high constable of France, to be beheaded without trial, on a suspicion of treason, and he afterwards invited King Charles of Navarre, with whom he had some differences, to an interview at Rouen, and there arrested him and put to death several lords of his suite. The brother of the King of Navarre and the relatives of the murdered lords applied to Edward III. of England for assistance. In 1355, Edward sent his son the Black Prince into France at the head of an army. After ravaging several provinces the Black Prince was met by King Jean near Poitiers, who with 80,000 men attacked the English, 10,000 in number, on the 19th September, 1356: the French were completely defeated, and Jean, after displaying much personal bravery and being wounded, was taken prisoner and conducted to London, where he was received by King Edward with great honour. Negotiations followed: Edward offered to renounce his assumed claim to the French crown on condition of being acknowledged as absolute sovereign of Normandy, Guienne, Calais, and other lands which had been held in fief by the former kings of England. Jean wanted to gain time, but meanwhile his own country fell into a state of horrible anarchy. The citizens of Paris revolted against the Dauphin Charles, and drove him out of Paris, and soon after the peasants or serfs, so long oppressed and brutalized by the feudal nobility, broke out into insurrection, plundered and burnt the castles of the nobles, and massacred all within them, men, women and children, with circumstances of frightful atrocity. This servile war, called La Jacquerie, from Jacques Bon-homme, the nickname given in derision to the French peasantry, lasted during the years 1357 and 1358, until the Dauphin and other great lords, having collected their forces, fell upon the peasants and massacred them by thousands, without giving any quarter. In May, 1360, peace was concluded at Bretigny between France and England, Edward giving up his claims to Normandy and France, and assuming the title of sovereign Lord of Aquitaine, with the consent of the Dauphin, who promised to pay a large ransom for his father. Jean was then restored to liberty, but he found so great an opposition among his nobles to the fulfilment of the conditions of the treaty, and was perhaps also made so uncomfortable by the confusion and wretchedness which prevailed in France, that he resolved, to the great astonishment of his courtiers, to return to England, to confer with Edward upon what was to be done. On arriving in London he took up his old quarters in the Savoy, and was received in the most friendly manner by Edward. He soon after fell dangerously ill, and died in London, in April, 1364. He was succeeded in France by his son Charles V.

JEAN SANS PEUR. [BOURGOGNE.]

JEAN DE MONTFORT. [BRETAGNE.]

JEAN D'ANGELY, ST., a town in the west of France, capital of an arrondissement in the department of Charente Inférieure, in 45° 57′ N. lat. and 0° 31′ W. long.; 240 miles in a straight line south-west of Paris, or 288 miles by the road through Orléans, Tours, Poitiers and Niort.

This town is on the right bank of the Boutonne, an affluent of the Charente, which here becomes navigable. In the dark ages succeeding the downfal of the Western Empire, St. Jean d'Angély, called in the barbarous Latin of the time Angeriacum, was the residence of the Dukes of Aquitaine, who had a castle here. In the place of this castle, Pepin le Bref built a Benedictine monastery. In the religious wars of the sixteenth century, the town, then of considerable importance, was besieged by the Huguenots under Count La Rouchefoucauld, A.D. 1562; but though the majority of the inhabitants were of the Reformed faith, the siege was not successful. It fell however into the hands of the Huguenots some time after; and though retaken, A.D. 1570, by the Catholic army under the Duke of Anjou (afterwards Henri III.), came again into the hands of the Huguenots. In A.D. 1621 it was taken from them by Louis XIII., who demolished the walls, and deprived the townsmen of their municipal privileges.

This town appears to be declining. At the commencement of the present century the commune had 8000 inhabitants: in 1831 it had 6031 (of whom 5326 were in the town), and in 1836, 5915. The chief trade is in timber and brandy. There are a college, or high school, a seminary for the priesthood, an agricultural society, a theatre, and baths.

JEDBURGH. [ROXBURGHSHIRE.]

JEDO, or JEDDO. [JAPAN.]

JEFFERSON, THOMAS. From the American Revolution of 1776 we may date the commencement of that struggle which has agitated and still agitates Europe and the two Americas. By whatever words the character of this struggle may be expressed,—whether under the name of popular rights against exclusive privileges, or self-government or the government of the people, against absolute government or the government of a few, or by any other terms more or less appropriate,—the contest is still going on, openly and actively in those called free governments, silently and languidly in those where the sovereign power is opposed to the extension or introduction of the new doctrines. The contest is between progress (not here considered whether as right or wrong) and standing still; between change, without which there cannot be improvement, and a desire to resist all change, which can hardly end in keeping things stationary, but almost necessarily leads to a backward movement. The contest is not only for the practical application of principles in government, which are vigorously maintained by the one party, and either not denied or faintly opposed by the arguments of the other; but also for the free expression and publication of all opinions on all subjects affecting the moral and political condition of society.

There is no individual, either in America or in Europe, who by his actions and opinions has had a greater influence on this contest than Thomas Jefferson. During a long and laborious life, both in official situations, which gave him opportunities that his activity never let slip, and in private life, in his extensive correspondence and intercourse with persons of all countries, he constantly, perseveringly, and honestly maintained what he conceived to be the principles

of pure republican institutions. In the ardour of youth, his zeal and energy mainly contributed to animate his countrymen to declare their independence on a foreign power. In his maturer age, when a member of the General Administration, he struggled, and he struggled at one time almost alone, against a monarchical and aristocratical faction, to maintain the great principles of the Revolution, and develop the doctrines of a pure unmixed popular government. His influence gave to these doctrines a consistency, and a form, and a distinctness, which the mass of the nation could easily seize and retain. He thus became the head of a party in the United States, which, whether always rightly appealing to his doctrines or not for the vindication of their acts, still regards him as the father of their school and the expounder of their principles. By his plain and unaffected manners, and the freedom with which he expressed his opinions on all subjects, he gave a practical example of that republican simplicity which he cultivated, and of that free inquiry which he urged upon all. Such a man must always have many friends and many enemies. From his friends and admirers he has received, perhaps, not more praise than those who believe in the truth of his doctrines and the purity of his conduct are bound to bestow; by his enemies, both at home and abroad, he has been blackened by every term of abuse that bigotry, malice, and falsehood can invent.

Thomas Jefferson was born April 2, 1743, at Shadwell, now in the county of Albemarle, in Virginia. He was educated at the College of William and Mary, at Williamsburg, then the capital of the colony, where, under Dr. Small, a native of Scotland, who was professor of mathematics in the college, he studied mathematics, ethics, and other branches of knowledge. His education, owing to the care of this excellent instructor and his own industry, must have been of a superior kind. In addition to his general acquirements, he made himself well acquainted with the best Greek and Latin writers, and to the end of his long life retained his ability to read them. Mr. Jefferson studied law under Mr. Wythe, then a lawyer of eminence. He made his first appearance at the bar of the General Court in 1767, at the age of twenty-four, about two years after the misunderstanding between Great Britain and the Colonies had commenced. He practised for seven or eight years in the General Court, and was gradually rising to the first rank as an accurate and able lawyer, when he was called away to more important duties by the political events that preceded the American Revolution. In 1769 he was elected a member of the House of Burgesses for the county of Albemarle. In the session of this spring the House unanimously came to resolutions in opposition to those which had been lately passed in England by both houses of parliament on the affairs of Massachusetts. This measure, which was accompanied with the declaration that the right of laying taxes in Virginia was exclusively vested in its own legislature, and others of a like tendency, induced the governor, Lord Botetourt, abruptly to dissolve the Assembly. The next day the members met at the Raleigh Tavern, and entered into articles of agreement, by which they bound themselves not to import or purchase certain specified kinds of British merchandise, till the act of parliament for raising a revenue in America was repealed; and they recommended this agreement to be adopted by their constituents. Eighty-eight members signed the agreement, among whom were George Washington, Thomas Jefferson, and others, who afterwards took a distinguished part in public affairs.

In 1773, on the meeting of the Virginia Assembly in the spring, Mr. Jefferson was an active member in organizing the Standing Committee of Correspondence and Inquiry, the main objects of which were to procure early intelligence of the proceedings of the British parliament, and to maintain a constant communication among all the Colonies. On the dissolution of the Assembly, in May, 1774, by the governor, Lord Dunmore, eighty-nine members met at the Raleigh Tavern, and, among other things, recommended the Committee of Correspondence to communicate with the Committees in the other colonies 'on the expediency of appointing deputies for the several colonies of British America, to meet in General Congress, at such place annually as should be thought most convenient,' to consult on their common interests. It was also forthwith agreed that the members who might be elected under the writs at that time issuing in the colony of Virginia should meet in Convention at Williamsburg on the 1st of August following, in order to appoint delegates to the Congress, if such General Congress should be approved by the other colonies. The Convention did meet, and thus formed the first popular assembly in Virginia uncontrolled by governor or council. Mr. Jefferson, who was one of the deputies, prepared instructions for the delegates who might be sent to the Congress. Being prevented by illness from attending on this occasion, his instructions were laid on the table for perusal, and were generally approved, but thought too bold in the existing state of affairs. Still the Convention printed them, in the form of a pamphlet, under the title of 'A Summary View of the Rights of British America.' The Convention drew up another set of instructions, which, though not so strong as Mr. Jefferson's, expressed with great clearness the points at issue between the colonies and the mother-country, and the grievances of which the colonies had to complain. The General Congress, consisting of fifty-five members, met at Philadelphia, September 4, 1774. The disputes which had broken out between Lord Dunmore and the Assembly of Virginia were continually increased by fresh causes of mutual irritation; and the governor at last thought it prudent to remove himself and his family into a British ship of war which was lying at York in York River. His whole conduct during this period was feeble and contemptible. His last acts from his head-quarters at Norfolk were to annoy the inhabitants on the rivers and bays by a predatory kind of warfare, to proclaim martial law in the colony, and to give freedom to such of the slaves as would bear arms against their masters. At last, after setting fire to Norfolk, he was obliged to take refuge in his ships, and soon after to leave the country. Thus ended the colonial government in Virginia.

On the 21st June, 1775, Mr. Jefferson took his seat in the General Congress, as one of the delegates from Virginia, and was appointed one of a committee for preparing a declaration of the cause of taking up arms. A part of the address which he drew up was finally adopted, and no doubt greatly contributed to bring about the more decisive declaration of the following year. In 1776, Mr. Jefferson was again a delegate to Congress, and one of a committee appointed to draw up a declaration of independence. The committee was chosen in the usual way, by ballot, and as Mr. Jefferson had received the greatest number of votes, he was deputed by the other members to make the draught. Before it was shown to the committee, a few verbal alterations were made in it by Dr. Franklin and Mr. (afterwards President) Adams. After being curtailed about one-third, and receiving some slight alterations in the part retained, it was agreed to by the House, July 4, and signed by all the members present, except one. This instrument is too well known to require any remarks. It has both merits and defects; but it served the purpose for which it was intended, and its author had the satisfaction of seeing the mighty question between the mother-country and the colonies referred to the decision of the sword, the only alternative then left except unconditional submission.

Before their adjournment the Virginia Convention, July 5, had elected Mr. Jefferson a delegate to Congress for another year; but he declined the honour on various grounds, among which was his desire to assist in reforming the laws of Virginia, under the new constitution, which had just been adopted. Congress also marked their sense of his services by appointing him joint envoy to France, with Dr Franklin and Silas Deane; but domestic considerations induced him to decline this honour also.

From this time Mr. Jefferson's public life is interwoven with the history of his native State, and with that of the United States. During the war he took no part in military movements. He was governor of Virginia in part of 1779, 1780, and part of 1781, in which year the state suffered considerably from the incursions of Lord Cornwallis; and at the close of his period of office he narrowly escaped being taken prisoner by Colonel Tarleton in his own house at Monticello.

In May, 1784, Mr. Jefferson was appointed by Congress minister to France, where he remained five years, during which he was actively employed in promoting the general interests of his country, and in keeping up an extensive correspondence. His industry and methodical habits enabled him to devote a great deal of his time to the examination of everything that could in any way prove beneficial to his countrymen. His correspondence during this period shows the variety of his pursuits, his unwearied industry, and his unbounded zeal for every improvement

that could benefit the social condition of man. His remarks on the political troubles of France, of which he witnessed the beginning, are characterized by his usual closeness of observation, and by his sanguine anticipations of the benefit that would result from the people being called to participate in the exercise of the sovereign power. After all that has been written on the subject, they will still be read with interest.

He returned to America at the close of 1789, and early in the next year he was appointed secretary of state by the president, General Washington. He held this office till the end of 1793, when he resigned. From 1793 to 1797 he lived in retirement. In 1797 he was elected vice-president of the United States; and in 1801 was chosen president in place of Mr. Adams, by the House of Representatives, on whom the election devolved in consequence of the equal division of the electors' votes between Mr. Jefferson and Colonel Burr. He was elected a second time, and after fulfilling his term of eight years retired to his favourite residence at Monticello, near the centre of the state of Virginia.

On Mr. Jefferson's retirement from the presidency of the United States he received, in the form of a farewell address, the thanks of the General Assembly of his native State, February 9th, 1809. After briefly recapitulating the leading measures of his administration, most of which faction itself must allow were eminently calculated to promote the happiness of the nation and secure those republican principles on which the constitution was founded, the General Assembly conclude with bearing testimony to his unvarying singleness of purpose, from the days of his youth, when he resisted the governor Dunmore, to his retirement from the highest honours which the united nation could bestow. This address, which, in point of style, is more free from objection than most American productions of the same class, is such as few men on retiring from power have received, and it was offered for services which few have performed.

In this document, among the advantages for which the nation was indebted to Mr. Jefferson's administration, the acquisition of Louisiana, and with it the free navigation of the Mississippi, are not forgotten. Mr. Jefferson early saw the importance of the United States possessing this great outlet for the commerce of the Western states, and strongly urged it while he was secretary of state under General Washington. The object was accomplished in 1803, when Louisiana was purchased from the French for 15,000,000 dollars.

Mr. Jefferson himself thought that the most important service which he ever rendered to his country was his opposition to the federal party during the presidency of Mr. Adams, while he was himself vice-president of the United States. Himself in the Senate and Mr. Gallatin in the House of Representatives had alone to sustain the brunt of the battle, and to keep the republican party together. The re-action that ensued drove Mr. Adams from his office, and placed Mr. Jefferson there. Mr. Jefferson's administration was characterized by a zealous and unwearied activity in the promotion of all those measures which he believed to be for the general welfare. He never allowed considerations of relationship or friendship to bias him in the selection of proper persons for offices; he always found, as he says, that there were better men for every place than any of his own connexions.

The last years of his life, though spent in retirement, were not wasted in inactivity. He continued his habits of early rising and constant occupation: he maintained a very extensive correspondence with all parts of the world; received at his table a great number of visitors, and was actively engaged in the foundation and direction of the University of Virginia, which was established by the state of Virginia near the village of Charlottesville, a few miles from Monticello.

No person but Mr. Jefferson could have had influence enough to induce the legislature of Virginia to grant the necessary funds for the endowment of this university. Though often baffled, he finally succeeded, by the help of his friends in that body, in obtaining ample grants for the buildings, library, and the salaries of the professors. He planned the buildings himself, and superintended their erection; drew up with his own hand a well digested and copious catalogue of books for a library, a large part of which were purchased in Europe and ready for use when the university opened in 1825; and he went so far as to prevail with the visitors of the institution to send an agent to Europe to select four of the professors. This last circumstance would show that Mr. Jefferson did not cherish such an unreasonable hostility to Great Britain as his enemies have charged him with.

The last letter in Mr. Jefferson's published correspondence, and it is probably the last that he wrote, is in reply to Mr. Weightman of Washington on behalf of the citizens of Washington, who had invited Mr. Jefferson to the celebration of the fiftieth anniversary of American independence. His health would not permit him to accept the invitation. His reply is characteristic. The zeal for republican institutions which had animated him during a long life still glows warm and fresh in the letter of a man of the age of fourscore and three, suffering under a painful malady. His firm conviction in the truth of those principles which he had maintained through life appears stronger as he approaches the termination of his career. He died July 4th, 1826, the day of the celebration, just half a century after that on which the Declaration of Independence was signed. Mr. Adams died on the same day. Mr. Jefferson is buried in the grounds near his own house. A simple inscription, which was found among his papers after his death, recording him as the author of the Declaration of American Independence, of the Statute of Virginia for Religious Freedom, and Father of the University of Virginia, is placed on his tomb. The fact of his having been president of the United States is not mentioned.

The latter days of Mr. Jefferson were embittered by pecuniary difficulties, which were owing in some measure to the neglect of his estates during his long absence on the public service; and in a great degree to an obligation which he incurred to pay a friend's debts (see an excellent letter to Mr. Madison, February 17th, 1826).

In the 4th vol. of his Memoirs, &c., p. 439, are printed his 'Thoughts on Lotteries,' which were written at the time when he was making his application to the legislature of Virginia for permission to sell his property by lottery, in order to pay his debts and make some provision for his family. The general arguments in defence of lotteries are characterized by Mr. Jefferson's usual felicity of expression and ingenuity, and they are also in like manner pervaded by the fallacies which are involved in many of his political and moral speculations. But this paper has merits which entitle it to particular attention. It contains a brief recapitulation of his services: and is in fact the epitome of the life of a man who for sixty years was actively and usefully employed for his country. 'I came,' he says, 'of age in 1764, and was soon put into the nomination of justices of the county in which I live, and at the first election following I became one of its representatives in the legislature; I was thence sent to the old Congress; then employed two years with Mr. Pendleton and Wythe on the revisal and reduction to a single code of the whole body of the British Statutes, the acts of our Assembly, and certain parts of the common law; then elected governor; next to the legislature, and to Congress again; sent to Europe as minister plenipotentiary; appointed secretary of state to the new government; elected vice-president and president; and lastly, a visitor and rector of the university of Virginia. In these different offices, with scarcely any interval between them, I have been in the public service now sixty-one years, and during the far greater part of that time in foreign countries or in other states.'

This is the outline of Mr. Jefferson's public life; to fill it up would be to write the history of the United States, from the troubles which preceded the Declaration of Independence to Mr. Jefferson's retirement from the presidency in 1809.

The paper from which we have already made one extract presents us with his services in another point of view, still more interesting. It is an epitome of those great measures which were due mainly or entirely to his firm resolution, unwearied industry, and singleness of mind, in his pursuit of objects which he believed essential to the stability and happiness of his country.

'If legislative services are worth mentioning, and the stamp of liberality and equality, which was necessary to be impressed on our laws in the first crisis of our birth as a nation, was of any value, they will find that the leading and most important laws of that day were prepared by myself, and carried chiefly by my efforts; supported, indeed

by able and faithful coadjutors from the ranks of the House, very effective as seconds, but who would not have taken the field as leaders.

'The prohibition of the further importation of slaves was the first of these measures in time.

'This was followed by the abolition of entails, which broke up the hereditary and high-handed aristocracy, which, by accumulating immense masses of property in single lines of families, had divided our country into two distinct orders of nobles and plebeians.

'But further to complete the equality among our citizens, so essential to the maintenance of republican government, it was necessary to abolish the principle of primogeniture. I drew the law of descents, giving equal inheritance to sons and daughters, which made a part of the revised code.

'The attack on the establishment of a dominant religion was first made by myself. It could be carried at first only by a suspension of salaries for one year, by battling it again at the next session for another year, and so from year to year, until the public mind was ripened for the bill for establishing religious freedom, which I had prepared for the revised code also. This was at length established permanently, and by the efforts of Mr. Madison, being myself in Europe at the time that work was brought forward.

'To these particular services I think I might add the establishment of our university, as principally my work, acknowledging at the same time, as I do, the great assistance received from my able colleagues of the visitation. But my residence in the vicinity threw of course on me the chief burden of the enterprise, as well of the buildings as of the general organization and care of the whole. The effect of this institution on the future fame, fortune, and prosperity of our country can as yet be seen but at a distance. That institution is now qualified to raise its youth to an order of science unequalled in any other state; and this superiority will be the greater from the free range of mind encouraged there, and the restraint imposed at other seminaries by the shackles of a domineering hierarchy and a bigoted adhesion to antient habits.'

When Mr. Jefferson was a member of the colonial legislature, he made an effort for the emancipation of slaves; but all proposals of that kind, as well as for stopping the importation of slaves, were discouraged during the colonial government. The importation of slaves into Virginia, whether by sea or land, was stopped in 1778, in the third year of the Commonwealth, by a bill brought in by Mr. Jefferson, which passed without opposition, and, as Mr. Jefferson observes, 'stopped the increase of the evil by importation, leaving to future efforts its final eradication.'* The Act for the Abolition of Entails was not carried without some opposition, and that for the abolition of the Established Anglican Church was not finally carried till 1786, though before the Revolution the majority, or at least a large number, of the people had become dissenters from the church. The reason of the difficulty lay in the majority of the legislature being churchmen.

Mr. Jefferson married, in 1772, Martha Skelton, the widow of Bathurst Skelton. She died ten years after their marriage. One daughter, and a numerous family of grandchildren and great grandchildren, survived him.

He was the author of 'Notes on Virginia,' which have been several times printed; but his reputation as a writer rests on his official papers and correspondence, of which latter, we believe, that which is published forms only a part of what he left behind him. 'His letters,' as his biographer remarks, 'especially those of his latter years, are written with great elegance and felicity. They have all the ease of Addison, with far greater precision. His style is always natural, flowing, and perspicuous; rarely imaginative and never declamatory. It was occasionally marked by neologisms where he thought there were no apt words already in use. It was neither diffuse nor concise, but more inclined to the former.' 'As an author, he has left no memorial that is worthy of his genius; for the public papers drawn by him are admired rather for the patriotic spirit which dictated them than for the intellectual power which they exhibit. They presented no occasion for novelty of thought or argument or diction. His purpose was only to make a judicious and felicitous use of that which everybody knew and would assent to; and this object he has eminently fulfilled.' But one of his letters (Tucker's *Life of Jefferson*, ii., p. 384) is of itself enough to exalt him to the rank of a first-rate writer. In a few words, he has sketched the character of General Washington—with a fidelity which belongs only to intimate knowledge, with a sincerity and love of truth which ennoble himself no less than the subject of his eulogy, with a precision and a force unrivalled by any literary essay of this kind, and with that profound but well-tempered admiration and respect which are due to the memory of so wise, so good, and so great a man. Much has been said and conjectured as to the religious opinions of Mr. Jefferson, and his supposed infidelity has been the ground of much bitter attack on his character. In the latter part of his life he used to call himself a Unitarian, when questioned on the subject by any of his friends. Perhaps his published correspondence presents the best means of judging of his religious opinions. Though decidedly approving of the morality which the Gospel inculcates, it does not appear that he can be ranked among any particular class of believers. (Tucker's *Life of Jefferson*, 2 vols. London, 1837; Jefferson's *Memoirs, Correspondence*, &c., London, 1829; *Journal of Education*, No. VII., *On the University of Virginia*, by Professor Tucker. This notice is reprinted from the 'Gallery of Portraits,' with a few alterations and additions.)

JEFFERSONITE, a variety of Pyroxene. [PYROXENE.]

JEJU'NUM. [INTESTINES.]

JELLY. [FOOD.]

JENA, a town in the Grand-Duchy of Saxe-Weimar, is situated in a romantic valley, partly surrounded by steep naked mountains, at the conflux of the Leutra with the Saale, over which there is a stone bridge of nine arches: 50° 56′ N. lat., 11° 37′ E. long. It consists of the town, through which the Leutra flows, and of the suburbs. The ramparts and moats which formerly surrounded the town have nearly disappeared. Jena is the seat of the supreme court of appeal for the Saxon Duchies and the principality of Reuss, and of several learned societies. It is however chiefly celebrated for its university, which was founded at the suggestion of the Elector John Frederick, who passing through Jena in 1547, as a prisoner of the emperor Charles V. after the battle of Mühlberg, advised his three sons to make Jena the nurse of the sciences, and the preserver of the pure Protestant faith, instead of Wittenberg, of which he had been deprived. The advice was followed, and when the elector, having recovered his liberty, returned in 1552, a considerable number of students went out to meet him. It was not till after long negotiations that it obtained from the emperor Ferdinand I. all the rights and privileges of a university, and was solemnly opened as such on the 2nd of February, 1558. It has always been its chief boast that it has zealously endeavoured to take advantage of the new views which have been opened from time to time, especially in philosophy. This tendency is evident in the two literary journals, one established in 1785 by Schütz, and one in 1805 by Eichstädt. The celebration of the festival on the Wartburg, the foundation of the Burschenschaft, and the circumstance that Sand, the assassin of Kotzebue, had resided last at Jena, did much injury to the university. These matters have in time been looked upon in a less unfavourable light, and the prohibition to Prussian subjects to study at Jena, issued in 1819, was revoked in 1825. The princes of Saxe-Weimar have always encouraged the university, and in our times it has been much benefited by a reform of the statutes, both of the university and the several faculties, by new laws for the students, and a considerable addition to its funds. The salaries of the professors have been increased, and a philological, theological, and homiletic seminary founded. The university has a large library, and there are in connection with it a botanic garden, a veterinary school, a school of midwifery, an anatomical theatre, a clinical institution, a collection of physical and mathematical instruments, a cabinet of minerals, an observatory, &c. There are 18 regular and 15 extraordinary professors, and several private teachers, making in all above 50. The number of students in 1837 was 569. The population of the town, exclusive of the university, is 5792. Jena has acquired additional celebrity in our times from the disastrous battle fought in its vicinity on the 14th of October, 1806, between the Prussian army under the Duke of Brunswick, and the French under Napoleon, in which the former was totally defeated and the duke mortally wounded. The consequences of the battle were even more fatal to Prussia than the battle itself,

* Act in Hening's 'Statutes at Large,' vol. ix., p. 471. Act declaring tenants of lands, or slaves in taille, to hold the same in fee simple. Hening, ix., p. 226.

and ended in the complete subjugation and humiliation of the kingdom. Jena and its environs suffered considerably, and what is now called the Eichenplatz was the site of 28 houses which were burnt on that occasion.

JENESEI. [SIBERIA.]

JENISEISK. [SIBERIA.]

JENNER, EDWARD, M.D., was born in 1749, at Berkeley, in Gloucestershire, of which his father was vicar. He was educated at Cirencester, and apprenticed to Mr. Ludlow, a surgeon at Sudbury. At the conclusion of his apprenticeship he went to London, and became a pupil of John Hunter, with whom he resided for two years while studying medicine at St. George's Hospital, and with whom his philosophical habits of mind and his love of natural history procured him an intimate and lasting friendship. In 1773 he returned to his native village, and practised as a surgeon and apothecary till 1792, when he determined to confine himself to medicine, and obtained the degree of M.D. at St. Andrew's University.

But the history of Jenner's professional life is embodied in that of vaccination. While at Sudbury he was surprised one day at hearing a countrywoman say that she could not take the smallpox because she had had cowpox; and upon inquiry he learned that it was a popular notion in that district, that milkers who had been infected with a peculiar eruption which sometimes occurred on the udder of the cow were completely secure against the smallpox. The medical men of the district told him that the security which it gave was not perfect; they had long known the opinion, and it had been communicated to Sir George Baker, but he neglected it as a popular error. Jenner during his pupilage repeatedly mentioned the facts, which had from the first made a deep impression on him, to John Hunter, but even he disregarded them; and all to whom the subject was broached either slighted or ridiculed it. Jenner however still pursued it; he found, when in practice at Berkeley, that there were some persons to whom it was impossible to give smallpox by inoculation, and that all these had had cowpox; but that there were others who had had cowpox, and who yet received smallpox. This, after much labour, led him to the discovery that the cow was subject to a variety of eruptions, of which one only had the power of guarding from smallpox, and that this (which he called the true cowpox) could be effectually communicated to the milkers at only one period of its course.

It was about 1780 that the idea first struck him that it might be possible to propagate the cowpox, and with it the security from smallpox, first from the cow to the human body, and thence from one person to another. In 1788 he carried a drawing of the casual disease, as seen on the hands of milkers, to London, and showed it to Hunter, Cline, and others; but still none would either assist or encourage him; scepticism or ridicule met him everywhere, and it was not till 1796 that he made the decisive experiment. On the 14th of May (a day still commemorated by an annual festival at Berlin) a boy aged eight years was vaccinated with matter taken from the hands of a milkmaid; he passed through the disorder in a satisfactory manner, and was inoculated for smallpox on the 1st of July following without the least effect. Jenner then entered on an extensive series of experiments of the same kind, and in 1798 published his first memoir, 'An Enquiry into the Causes and Effects of the Variolæ Vaccinæ.' It excited the greatest interest, for the evidence in it seemed conclusive; yet the practice met with opposition as severe as it was unfair, and its success seemed uncertain till a year had passed, when upwards of seventy of the principal physicians and surgeons in London signed a declaration of their entire confidence in it. An attempt was then made to deprive Jenner of the merit of his discovery, but it signally failed, and scientific honours were bestowed upon him from all quarters. Nothing however could induce him to leave his native village, and all his correspondence shows that the purest benevolence, rather than ambition, had been the motive which actuated all his labours. 'Shall I,' he says in a letter to a friend, 'who, even in the morning of my life, sought the lowly and sequestered paths of life, the valley and not the mountain—shall I, now my evening is fast approaching, hold myself up as an object for fortune and for fame? My fortune, with what flows in from my profession, is amply sufficient to gratify my wishes.' Till the last day of his life, which terminated suddenly in 1823, he was occupied in the most anxious labours to diffuse the advantages of his discovery both at home and abroad; and he had the satisfaction of knowing that vaccination had even then shed its blessings over every civilized nation of the world, prolonging life, and preventing the ravages of the most terrible scourge to which the human race was subject.

Jenner's other works all evince the same patient and philosophical spirit which led him to his great discovery. The chief of them was a paper 'On the Natural History of the Cuckoo,' in which he first described that bird's habit of laying its eggs singly in the nests of smaller species, to whom it leaves the office of incubation and of rearing the young one, which, when a few days old, acquires the sole possession of the nest by the expulsion of its rightful occupants. Indeed he gained so much credit by this paper, that he was recommended not to send his account of vaccination to the same Society, lest it should injure the scientific reputation which he had already obtained.

The life of Jenner has been written by his friend Dr. Baron of Gloucester, in 2 vols. 8vo. Five medals have been struck in his honour, of which three were produced in Germany, and a statue is erected to him in his native county. But it is remarkable that the only public testimonials awarded by his country to the man whose unaided intellect and industry have added more years to the lives of men than the united labours of any century, were grants of 10,000*l.* and 20,000*l.*, which were voted to him by the House of Commons in 1802 and 1807.

JENYE. [HINDUSTAN, p. 216.]

JENYNS, SOAME, born 1704, died 1787, enjoyed a considerable reputation in his lifetime from the happy accident of uniting good birth and fortune with a creditable share of literary accomplishment and success. His family property was at Bottisham, near Cambridge; he was educated at St. John's College; elected M.P. for the county in 1741; for the borough of Dunwich in 1754; for the town of Cambridge in 1761, which last he represented until his withdrawal from public life. In 1755 he was made a lord of trade, and he held that office in spite of political changes until its abolition in 1780, being a steady supporter of all existing administrations. As a versifier he is elegant and sprightly; sometimes rather free: his poems, which consist of 'The Art of Dancing,' 1728, and 'Miscellanies,' 1770, have found admission into the 2nd and 3rd editions of Johnson's Poets. His prose works are:—1. 'A free Inquiry into the Nature and Origin of Evil,' 1756. This unsatisfactory attempt to solve one of the most difficult of moral problems was very ably and severely criticised by Dr. Johnson in the 'Literary Magazine,' and this rebuke Jenyns seems never to have forgiven. (See Boswell's *Life*, under the above year.) 2. 'View of the Internal Evidence of the Christian Religion,' 1776, for the divine origin of which he argues from its utter variance with the principles of human reason. This was a curious ground for a friend to take; and though the book obtained much praise, there were many also who regarded it as the work of a disguised enemy. This does not seem to have been the case; Jenyns, though once a sceptic, was in the latter part of his life a professed, and, as Boswell, who was no friend to him, believed, a sincere Christian. 3. Dissertations on various subjects, 1782. These are political and religious. His prose writings have obtained much praise for elegance of style, art, shrewdness of remark, and aptness of illustration; but his talent was better suited for the lighter and more showy parts of literature than for metaphysics and controversial theology. He published some pieces not here mentioned. His Works are collected in 4 vols. 8vo., 1790-3, with a Life, by Mr. Cole.

JER-FALCON, or GYR-FALCON, the English name of the *Falco Islandicus* of Latham, *Gerfaut* of the French, *Hebog chwyldro* of the Antient British. [FALCONIDÆ, vol. x., p. 182.]

JERBOA. [MURIDÆ.]

JEREMIAH (Heb. יִרְמְיָהוּ; LXX. Ἱερεμίας), one of the prophets of Judah, the writer of the greater part of the book in the Hebrew canon which bears his name, and of the whole of the book, succeeding it in that canon, called 'The Lamentations.'

He was of the sacerdotal family, being the son of Hilkiah, a priest, whose residence was at Anathoth in the land of Benjamin, about three miles north of Jerusalem. This we learn from the general title to his book of Prophecies (chap. i., ver. 1), and that title sets distinctly before us the

period through which he flourished. He was called to the prophetic office, being then in his youth, in the thirteenth year of King Josiah, which, according to the received chronology, was 629 years before the Christian æra commences. He continued in the prophetic office till the eleventh year of King Zedekiah, that is, till 588 B.C. Nearly all the prophecies collected in this book were delivered by him in those reigns, and in the intermediate reigns of Jehoahaz, Jehoiakim, and Jehoiachin, the unhappy family of Josiah. He consequently witnessed the death of Josiah, who was slain in battle by the king of Egypt, the deposition of Jehoahaz, and the two great invasions of the kingdom of Judah by Nebuchadnezzar, king of Babylon, who in the first carried away Jehoiachin and many of the people captive, and in the second carried away still more, with Zedekiah the king, whose eyes he caused to be put out when he had slain his sons and many of his nobles in his presence. Then it was that ensued the burning of the king's palace and of the temple which had been erected by Solomon, and of the whole city of Jerusalem, in that fatal fifth month and seventh day of the month which was long remembered in the calendar of Jewish calamities.

These things saw Jeremiah; and in the midst of all this scene of misery his voice was often raised, as one of the prophets of Jehovah, to deplore the calamities which fell upon his country, or with the voice of warning to call his countrymen to depart from the offences which had provoked those sufferings, and to turn themselves to God, both in outward observances and in inward purity and conformity of heart.

His contemporaries in the prophetic office were in the earlier periods Zephaniah and Habakkuk, and in the latter his æra approaches near to that of Ezekiel and Daniel.

The book entitled his Prophecies is a collection of such prophecies or exhortations as he delivered at various times, mingled with relations of historical events. The last chapter, the fifty-second, is wholly historical, and is supposed to have been written by some other person, not improbably Ezra, and to be intended as a kind of introduction to the book of Lamentations which follows it. But the most remarkable circumstance relating to the composition of the book is this, that the various prophecies are put together without any regard to the order of time in which they were delivered. At the beginning indeed we have the account of his call to the prophetic office, but as we proceed we soon find that we have prophecies delivered in the reign of Jehoiakim following others which were delivered many years after in the reign of Zedekiah.

However, this does not lead to any serious inconvenience or occasion any important difficulty, as we are generally informed in whose reign and at what time the several distinct prophecies were delivered. They are very easily distributed in the chronological order by any one who is desirous to do so, and thus to obtain a more distinct idea of the object of the prophet, and the relation of these compositions to the time at which he lived; and on this account we omit the chronological arrangement of the several prophecies, either as following Dr. Blayney, or the German critic Rosenmüller, or proposing any other of our own. Those who desire to read the Scriptures with understanding can have no more agreeable and profitable exercise than thus to refer the writings of the prophets to the period of Jewish history to which they belong, and to observe how suitable they are to the then state of the people of God, and to the character which the prophets sustained among them.

The tone in which Jeremiah addressed the people was frequently disapproved by the political authorities of the time. He appears to have been an ever-faithful witness to the Most High, and to have sought to support his honour as well in the good days of King Josiah as in the evil days of his degenerate sons. In the later reigns it was said that he dispirited the people, and that they were rendered by him less energetic in the resistance which they offered to the armies of Chaldæa. This led to his being placed under restraint and punished.

Hitherto our remarks have been confined to the first forty-two chapters and to the fifty-second, the last. But when we arrive at the forty-third chapter we find a new and very important circumstance in the life of Jeremiah. In neither the first nor the second captivity was Jeremiah carried away with his countrymen and king to Babylon: he still remained in Judæa, lamenting her fallen and desolate state, and exhorting and encouraging the remnant of the people to continue in the land till they should be forcibly expelled. This was distasteful to a powerful party, who thought they saw in Egypt a safe place of retreat from the power of the king of Babylon, and who finally led the people that remained into that country, carrying Jeremiah with them. They settled at a place called Taphanhes, which is probably the Daphnæ of the Greek geographers. The forty-fourth chapter is an exhortation which he delivered to his countrymen in Egypt. But in the forty-fifth chapter we are carried back to the times of King Jehoiakim; so little of order and regularity is there in the making up of this book. After this there follow various predictive discourses delivered by Jeremiah at various and uncertain periods concerning other nations, the Egyptians, Philistines, Moabites, Ammonites, Edomites, and others, ending with an awful denunciation against Babylon, in which the utter desolation of that great and flourishing city is predicted, and the return of the people from their long captivity. The prophecy of the utter abolition of Babylon, so that its site should become a place for the abode of wild beasts of the desert, is very remarkable.

The sacred books contain no later information concerning the prophet than that he was among those who went to Taphanhes. But some of the early Christian writers relate of him that he was stoned to death by his countrymen in Egypt for preaching against their idolatry.

Two very different accounts are given of the occasion on which he wrote the book of Lamentations. The old opinion, after Josephus, was that it was written on the death of King Josiah: but the later and more probable opinion is that it is a bewailing of the lost state of Judæa when it had suffered so dreadfully from the armies of Nebuchadnezzar. It is a very tender and pathetic poem, consisting of five portions, or, as they may be considered, distinct elegies. The structure is very artificial, the successive stanzas in each of the elegies beginning with the letters of the alphabet taken in order. Some of the Psalms are also in their structure of this form.

Some persons have imagined that they see in the style of Jeremiah proofs of original rusticity. There are not the dignity and splendour of Isaiah, but there are great beauties peculiar to this prophet, whose province appears rather to be the expression of grief and concern than of glowing indignation.

JERICHO. [SYRIA.]

JERICHO, ROSE OF, is the popular name of a plant called by botanists Anastatica Hierochuntica. It is a native of Palestine and other parts of the East, and, when alive, is a small inconspicuous annual, with branches regularly spreading round the centre. When it dies, these branches curl up so as to form a sort of ball, and, the root decaying, are blown about in the dry weather which succeeds their short-lived growing season. If at that time they are placed in a wet situation, their hygrometrical properties cause them to unfold, and to assume something the appearance of a rose, a simple phenomenon to which the people of the East have attached the fable that the plant first blossomed at the moment when our Saviour was born, and that now, if put into water when labour commences, it will indicate by its expansion the progress of parturition, and will finally expand when the child is born. The Jews call it Kaf Maryam, or St. Mary's Flower.

JEROME, SAINT, one of the Fathers of the Church, and accounted the most learned of all the Latin Fathers. He was well acquainted with both the Greek and Hebrew languages.

His æra was from A.D. 340, about which time he was born, to A.D. 420, in which year he died. He was a native of Pannonia, but came early to Rome, where he studied under the grammarian Donatus. When he had received baptism in token of his professing the Christian faith, he entered upon a long course of travel. He visited Gaul, where he remained some time, and afterwards travelled in Thrace, Pontus, Bithynia, Galatia, and Cappadocia. When he was about thirty he began to be noted for his theological knowledge. In a retirement which he had chosen for himself in Syria he was disturbed on a suspicion of the want of perfect soundness in the faith. This determined him to go to Jerusalem, and there apply himself to the study of the Hebrew language as the best means of enabling him to understand the Scriptures rightly, not only of the Old, but also of the New Testament. In A.D. 382 he returned to Rome, having spent some time at Constantinople on his

way, where at that time lived St. Gregory of Nazianzus, a celebrated preacher. At Rome he became secretary to Pope Damasus. There appear to be circumstances in the life of Jerome at this period which are not cleared up. It is however certain that Sericius, the successor of Damasus, had not the same esteem for him which Damasus had, and that Jerome left Rome and returned to the neighbourhood of Jerusalem. There he took up his abode in a monastery at Bethlehem.

In this retirement he employed himself in writing on the questions wh ch then divided the opinions of Christians, and here it is believed he died, at the age of eighty years.

Many of the writings of Jerome are come down to us. Several of them are merely controversial; but there are others of a more sterling and lasting value. These are, his treatise on the Lives and Writings of the elder Christian Fathers, and his Commentaries on the Prophetical Books of the Old Testament, on the Gospel of St. Matthew, and several of St. Paul's Epistles. But what may be regarded as his greatest work is a translation of the books of both the Old and New Testament into Latin, which translation has been always highly valued in the Latin Church, and which is that known in the Church by the name of the Vulgate. It is a question amongst the learned how far, and whether at all, he embodied an older Italic version in his translation. If it was the first effort at bringing the Scriptures within the reach of the great multitude who knew no other language but the Latin, it was a great and noble work, which ought to place its author high amongst the benefactors of mankind. Bishop Warburton says of Jerome, that 'he is the only father that can be called a critic on the sacred writings, or who followed a just or reasonable method of criticising.' A treatise of his was one of the first books printed in England. The best edition of his works is that of Vallarsius, in 10 folio volumes, printed at Verona, 1734—40.

JEROME OF PRAGUE. [Huss.]

JERSEY, an island in the English Channel, about 18 miles south-east of Guernsey, measuring in a straight line between the nearest points of the two islands: between 49° 9′ and 49° 16′ N. lat., and 1° 58′ and 2° 14′ W. long. Its form approximates to a quadrangle, having its sides facing the four cardinal points. Its greatest length from east to west is about 12 miles; its greatest breadth from north to south about 7 miles. Of its area we have no account: the population in 1831 was 36,582.

The surface of the island has a gradual slope from north to south. On the north side the coast is abrupt, rising to the height commonly of 100, sometimes of 200 feet, and broken by a succession of small bays and coves, one of which, Bouley or Boulay bay, has been several times surveyed, in order to the formation of a naval station, for which its easy access and good anchorage seemed to offer considerable facilities. A pier on a limited scale has been erected here by the States of Jersey. On the east side of the island are two bays, St. Catherine on the north-east, where the coast is abrupt; and Grouville on the south-east, with a low shelving beach. On the west side is the wide shallow bay of St. Ouen, with a shelving sandy beach, skirted in nearly all its extent by ledges of rocks. On the south side of the island the character of the coast is less uniform; at the bottom of the deep bays of St. Aubin and St. Brelade it is low and shelving, with a broad belt of sand nearly a mile wide in St. Aubin's bay, and dry at lowwater. The headlands at the south-west point of the island, and between the before-mentioned bays, are lofty and abrupt; between St. Aubin's bay and the south-east point of the island the coast is low, but skirted by extensive ridges of rocks. St. Aubin's bay, on which stand the towns of St. Helier and St. Aubin, is the most frequented; but most of the bays afford anchorage.

Groups of rocks surround the island at various distances from it; there are also many banks and shoals.

The surface of the island is everywhere undulating. The valleys generally run from north to south; they are narrow at the north end, where the high ground forms an almost unbroken hill, and grow wider as they approach the southern coast, where they expand into several flats of good pasture land. A few valleys open to the eastern and western sides of the island. The principal water-courses flow from north to south; they are more considerable than from the size of the island would be supposed, and serve to give motion to several mills. The valleys watered by these streams are 'as rife in beauty as wood, pasturage, orchard, a tinkling stream, and glimpses of the sea can make them.' (Inglis's *Channel Islands*.)

The high land in the northern part of the island consists for the most part of granitic rocks; the southern part of a mass of schistose rocks incumbent upon them. The high rocks which stretch away to sea all round Jersey seem to be of granitic formation. The rocks along the northern coast consist for the most part of sienite; they present perpendicular faces to the sea, and are everywhere intersected by perpendicular veins running north and south, which have formed many remarkable caverns where they have been exposed to the action of the sea. The sienite is quarried on the northern coast; part of the stone is used on the island, part is exported to Guernsey and England, and, in time of peace, to France. No metallic traces, except of iron, have been observed in Jersey; the schistose rocks have not afforded any slates for economical purposes; nor does the island yield any lime. Jersey was until of late years ill provided with roads, for the old roads, though numerous, are narrow and inconvenient. The new roads, which are also numerous, are wide and well constructed, and traverse the island in many directions.

The climate of Jersey, from its insular situation, is milder than that of other places under the same latitude, and the mean annual temperature is higher than that of any part of England. Snow and continued frost are rare, but there is much rain, and the dews are very heavy. High winds are prevalent and violent; gales frequently blow, especially from the west; a perfectly calm day even in summer is rare. The predominant diseases are rheumatism, chiefly chronic, liver complaints, indigestion, dropsy, hypochondriasis, and remittent, typhoid, and intermittent fevers. Rheumatism, the most prevalent disease, is ascribed to the humidity of the atmosphere.

The state of agriculture in Jersey is backward, which is partly owing to the minute subdivision of property, arising from the custom of gavelkind. Rents are about 4*l.* 10*s.* per English acre for the average of good land, and above 5*l.* for the best. The expenses of the farmer are however light, and the productiveness of the soil great. Wheat is the principal grain crop; barley is grown, and some oats; parsnips are extensively grown and used for fattening hogs and bullocks. Potatoes for exportation are widely and increasingly cultivated. Lucerne is one of the most valued crops. A considerable portion of the land is laid out in orchards: the apples are converted into cider, which constitutes the most important produce of the island; then follow potatoes, lucerne, and wheat. The principal manure is vraic or sea-weed, either fresh, or after it has been burnt for fuel; fresh vraic is preferred for grass land, vraic ashes for other crops. Fallows are seldom seen. The wheat harvest commences about the beginning of August. The common English fruits are raised in Jersey, and the melon and the grape grow in the open air.

The cow is an object of great attention in Jersey. The breed is one variety of that known in England as the Alderney, but is considered to be deteriorating. Jersey butter is in high esteem; and great quantities, fresh and salt, are exported. A few sheep are kept only by the poorer classes who have right of common. Little attention is paid to horses: the breed was crossed with the Cossack horses during the stay of some Russian troops in the island in the year 1800. Of game there are the hare and the rabbit, and the red-legged partridge. Toads are numerous, as well as snakes and lizards. The fish caught in the island are similar to those of Guernsey. [Guernsey.]

Jersey is divided into twelve parishes. The parishes are subdivided into 'vintaines' ('scores'), supposed to be so called from having originally contained twenty houses. Of these vintaines there are from two to six in each parish, and in all fifty-two.

There are three towns in the island, St. Helier and St. Aubin [Aubin, St.], both on the Bay of St. Aubin, and Gorey, on the east coast. St. Helier is toward the south-east point of the bay, and fronts the sea. In external appearance it is much on a level with English country towns of the same size; except that the ramparts of Fort Regent, overtopping the buildings, give to the place the appearance of a continental town. The houses in the more central parts of the town are chiefly inhabited by the shopkeepers; those in the outskirts, extending to the foot and up the slopes of the surrounding heights, are tenanted by the more opulent merchants, and by the nu-

merous English residents, of whom there are computed to be 3000 in the island, many of them half-pay officers and their families. Some of the new streets in the outskirts are regular and well built, and have open spaces and ornamented garden ground in front of them. The principal public buildings are, the old church, two of the chapels, the theatre, and the gaol; of these, only one of the chapels, built in the Gothic style, and the portico of the theatre, have any claim to architectural design. The market is almost unequalled in the season for its display of garden produce. The Royal Square is an open space, flagged with smooth stones, surrounded by the principal book-shops, newspaper offices, reading-rooms, the court-house, and one of the principal hotels. There are two fortresses: Elizabeth Castle on a rock in the bay opposite the town, which would be insulated at high water but for a narrow causeway formed by the confluence of the tides between the castle and the shore; and Fort Regent, a strong fortification, commanding the town, of considerable strength, but inadequate accommodation. The harbour is formed by two piers jutting out into the bay at the south end of the town.

Gorey is in Grouville parish, and on Grouville Bay. It is built partly close to the sea and partly on the height which rises toward Mont Orgueil Castle. The importance of Gorey depends on its oyster fishery, in which upwards of two hundred and fifty boats, half of them belonging to the island, and as many as fifteen hundred sailors, are employed, besides a thousand persons, chiefly women and boys, who are engaged in matters connected with the fishery. The larger oysters are sent to St. Helier for sale, the smaller are sold and transported to the English oyster-beds. The produce of this fishery is supposed to bring to the island 20,000*l.* or 30,000*l.* per annum. In the neighbourhood of Gorey is Mont Orgueil Castle, once the principal fortress of the island, on a headland between St. Catherine's and Grouville bays. Its commanding situation on a rocky headland jutting into the sea, and commanding a fine land and sea view, and its massive walls, in many parts yet entire and mantled with ivy to their very summits, render it a picturesque and striking object. It was the place of confinement of Prynne, and the residence of Charles II. during part of his exile.

The other places in the island are mere hamlets, grouped round the churches of the several parishes or scattered along the coast. Scattered over the island are the antient manor-houses, and there are several modern villas, especially near the towns. Every house and cottage, not in a street, has its garden. Myrtles, hydrangias, and various other plants which in England commonly require shelter, grow luxuriantly in the open air.

The churches are of various dates, but all of considerable antiquity; their situation is in general well chosen, but they present no particular architectural beauties.

Much of what has been said of the state of society and the constitution of the local government in Guernsey [GUERNSEY] will apply to Jersey. The spirit of independence is very generally diffused; industry, the love of gain, and a frugality degenerating into penuriousness, are characteristics of the island character. The common diet among the farmers and country people is 'soupe à choux,' or 'soupe à la graisse,' made by boiling together cabbage, lard, and potatoes; sometimes, but rarely, a little meat is added, and parsnips or turnips are substituted for potatoes. Cider is the common drink. This meagre diet has probably contributed to a deterioration of the inhabitants both in stature and appearance.

The states of Jersey consist of the governor and the bailly of the royal court, both appointed by the crown; the twelve judges of the royal court (the court of judicature for the island in civil and criminal cases), elected to office for life by the suffrage of the rate-payers; the rectors of the parishes, appointed to their livings by the governor; and the twelve constables elected every three years, one for each parish, by the inhabitants. The officers of the crown have seats, and can speak, but not vote. Local politics engross the greatest attention, party spirit rages furiously, and has a very unfavourable effect on the constitution of the royal court, the judges of which are appointed by popular suffrage, and generally after a vehement party struggle.

The dean of Jersey, who is appointed by the crown and is always rector of one of the twelve parishes, is at the head of the church of the island, and holds a spiritual court, from which there is an appeal to the see of Winchester. The livings are all small (the great tithes going to the crown), and there are no pluralities.

There are two antient chartered schools, with inadequate endowments; one of them, that of St. Anastase, has no scholars, and the other, that of St. Manelier, is in a languishing state. There are however a National School at St. Helier, some parish schools with slender endowments, and several private seminaries and Sunday schools. Elementary instruction is very generally diffused, and there is scarcely a child in the island who is not at school. There is an island 'hospital' or poorhouse, but without any general medical or educational departments, and every way inferior to that of Guernsey. [GUERNSEY.] There are several newspapers, some in French and others in English; they are for the most part devoted to party interests, and much seasoned with personalities.

The trade of Jersey, owing to the privileges possessed by the islanders, is very considerable. The agricultural produce of the island, potatoes, apples, cider, butter, cows, and other live stock, are sent to England; the articles required for the consumption of the island being in a considerable degree supplied from France. Foreign wheat is made into biscuit, and foreign leather into boots and shoes, and exported to the British colonies as 'Jersey manufacture;' and vessels, which are admitted to register as British, are built with foreign materials. The shipping belonging to the island has an aggregate tonnage of 21,000, beside 300 large boats.

The general history of the Channel Islands has been noticed elsewhere. [GUERNSEY.] Jersey, the Cæsarea of the Romans, is said to have been originally called Augia. In the reign of Edward III. this island was attacked by Du Gueselin, constable of France, but the arrival of succours from England prevented him from succeeding. In the war of the Roses it was attacked by a Norman baron, Pierre de Breze, avowedly for the Lancastrian party, but really for the French king. After holding part of the island for a time, he was forced to surrender. Henry VII., while earl of Richmond and an exile, and Charles II., while an exile, both before and after his father's death, found refuge in Jersey, which was held for Charles by the valour and constancy of Sir George Carteret until taken by the Parliamentarians under Admiral Blake and General Haines.

During the first American war, Jersey was thrice attacked. The first time (May, 1779) was by an armament with a land force of 5000 or 6000 men, under the prince of Nassau, but the attempts to land were repulsed. In the second attack the French fleet was attacked and destroyed by Sir James Wallace. The third attack was in December, 1780, when the Baron de Rullecourt landed with 700 men, took possession of St. Helier, and made the lieutenant-governor, Major Corbet, prisoner, and induced him to sign a capitulation. The British troops and island militia, under Major Pierson, next in command, refused to recognise the capitulation; and attacking the French, killed Rullecourt, with the greater part of his men, and obliged the rest to surrender. Major Pierson fell in the beginning of the attack.

JERSEY, NEW, one of the republics of the United States of America, extends from 38° 55′ to 41° 21′ N. lat., and from 74° to 75° 45′ W. long. Its length from south to north is 170 miles, and its mean breadth 46 miles. Its surface is estimated at 7870 square miles, which exceeds that of Wales by 400 square miles. Delaware river and bay divide it on the west from the states of Pennsylvania and Delaware, and the Hudson river on the east for a short distance from New York. An imaginary line, 45 miles long, forms its northern boundary towards New York. On the east and south it is washed by the Atlantic and Delaware Bay.

About one half of its surface, including all the country south of a line drawn from Bordentown on the Delaware river to Shrewsbury on the eastern coast, is so level that it is difficult to distinguish the watershed between the streams which fall into the ocean from those which empty themselves into Delaware Bay. All this tract is covered with a sea-sand alluvium, and parts of it are completely barren. The western shores along Delaware bay are covered with salt-marshes, which produce a coarse hay. Along its eastern shores there is a series of long, narrow, and low islands, similar to those along the coast of the two Carolinas; but the inlets by which those islands are divided are deeper and more spacious, and vessels of moderate draught can enter the ports of Great Eggharbour, Little Eggharbour,

Barnegat, Tomsbay, and Shark Inlet. North of the line drawn from Bordentown to Shrewsbury the country is hilly, but the hills are of moderate elevation, and the wide valleys between them have a good loamy soil. At the eastern extremity of this tract, and immediately on the sea-shore, are the Neversink hills, which, though only 281 feet above the sea-level, are the highest eminences on the Atlantic shores from Florida Cape (25° 50′ N. lat.) to this point (40° 25′). The hilly tract covers somewhat more than one-fourth of the surface of New Jersey. The most northern portion is divided between a marshy and a mountainous tract: the former lies along the banks of the river Hudson, and extends about 10 miles from them on an average; it is of moderate fertility. The mountainous tract occupies the remainder, and contains two ridges, which traverse the north-western corner of the state in a direction south-west and north-east. The southern chain is called the Blue Ridge, and the northern the Kittatinny Mountains; in the latter is Shooley's Mountain, 1100 feet above the sea. These ridges are mostly covered with forest trees, and the country between them has a good soil.

The large rivers of this state are those which constitute its boundary, the Hudson [NEW YORK] and the Delaware [DELAWARE]. A canal has been cut between these two large rivers, called the Morris canal, which traverses the northern districts of the state. It leaves the Delaware at Philipburgh, opposite Easton, and runs in the valley between the Blue Ridge and the Kittatinny Mountains north-east; it is then carried through a depression of the first-mentioned ridge, and along the Passaik river eastward and southward to Newark; it then crosses that river and passes through the marshes to Jersey city, opposite New York, where it joins the Hudson. Its length is somewhat more than 100 miles. Among the minor rivers the Rariton is the largest. It traverses the hilly district and falls into Amboy Bay, which is a good harbour for vessels of middling size. The Rariton is navigable for 16 miles from its mouth. Newark Bay also receives the Hackensack and the Passaik, of which the former is navigable for 16, and the latter for about 10 miles from its mouth. The Maurice river, which empties itself into Delaware Bay not far from Cape May, the southern extremity of the state, is said to be navigable for vessels of 100 tons to a distance of 20 miles from its embouchure.

The difference in climate between the southern and northern districts is very great, and depends mainly on the difference of elevation. The level sandy plains of the southern districts approximate to the temperature of Eastern Virginia, and admit the cultivation of cotton, while the mountainous northern districts experience early and severe winters, and in this respect resemble Vermont and New Hampshire. The vegetable productions are seldom injured by drought or excess of rain.

Wheat, rye, Indian corn, oats, barley, buck-wheat, flax, and potatoes are the common crops; buck-wheat is in very general cultivation. The cotton grown in the southern district is consumed for the domestic manufactures. Apples, pears, peaches, plums, and cherries are the common fruit-trees, and they succeed exceedingly well. The Jersey cider is noted for its superior quality. In the mountainous parts and salt-marshes near the sea-coast great numbers of cattle are raised. Sheep are also kept in great numbers. The sea abounds in fish, and the inhabitants of the coast derive a great portion of their subsistence from the fisheries. The forests are composed of oak, hickery, chesnut, poplar, ash, &c. The larger wild animals have nearly disappeared, and only the racoon and the red and grey fox abound. Iron abounds in the mountainous and hilly district, and bog iron is found in the marshes along the sea. There is also copper, and, in the primitive rocks of the mountainous districts, gold, silver, and galena.

The inhabitants amounted in 1830 to 320,823. The state is divided into 14 counties and 120 townships. The principal occupation of the inhabitants is agriculture; but the surplus population has lately turned to manufacturing industry, and in some branches a considerable progress has been made, though the distress of late years has caused a depression. Besides numerous iron-works, several glass-houses, tanneries, gunpowder-mills, and cotton manufactures are established, mostly in the hilly country, which is the most populous.

Trenton, on the Delaware, the capital and the seat of government, is a small place, with about 4000 inhabitants, and some cotton manufactures. The largest towns are in the hilly district, where New Brunswick, on the river Rariton, at the head of tide-water, contains 8000 inhabitants, and has some commerce, and a college; and Newark, on the Passaik river, with about 10,000 inhabitants, carries on a considerable trade with New York, and has manufactures of carriages, shoes, and saddles. Patterson, on the Passaik, which forms near the town a cataract 70 feet high, is the principal manufacturing town of the state, and contains near 8000 inhabitants. The principal articles made here are iron and brass wire, and cotton-cloth. Perth Amboy, situated where the Rariton falls into Amboy Bay, has a harbour, but only 1000 inhabitants. It is the oldest settlement in the state. South Amboy, on the opposite side of the bay, has a population of near 4000. The towns of Shrewsbury and Freehold, both on the eastern shores, have some commerce, and each of them about 5000 inhabitants. At Princeton, between Trenton and New Brunswick, there is a college, called Nassau Hall, one of the oldest establishments in the United States, and also a theological seminary.

That none of the maritime towns of this state have risen to importance is easily accounted for by the vicinity of New York and Philadelphia, to which the produce of the country is sent. This produce consists of live cattle, fruit, iron, butter and cheese, hams, flax-seed, cider (of which that of Newark is the best), lumber, and some manufactures, especially leather, glass, cotton-cloth, and iron-ware.

Besides the canal already described, the Delaware and Rariton canal, which is 38 miles long, runs from near Trenton to New Brunswick. The Camden and Amboy railroad, which is 61 miles long, forms a line of communication between Pennsylvania and New York, passing by South Amboy. The Patterson and Hudson River railroad, which is 14 miles long, connects Patterson with Jersey city.

New Jersey was first settled by the Dutch in 1612, in those places contiguous to the Hudson river. The Swedes established themselves here in 1628, but their settlements soon fell into the possession of the Dutch, who were supplanted by the English in 1664. New Jersey was then a part of New York, from which it was definitively separated in 1736. It declared itself early against England in the revolutionary struggle, and published its present constitution on 2nd July, 1776, two days before the declaration of independence by the Continental Congress. The legislature consists of a legislative council of 14 members, and of a general assembly of 50 members. The judges hold office for a fixed number of years. New Jersey sends two members to the senate at Washington, and six to the house of representatives. (Darby's *View of the United States*, and Warden's *Account of the United States*.)

JERUSALEM, the chief city of Palestine, in Syria, situated in 31° 47′ N. lat. (according to Niebuhr), 35° 19′ E. long.; 38 miles east from the nearest point (near Ashdod) towards the Mediterranean, and 27 miles west from where the river Jordan enters the Dead Sea.

The name is written יְרוּשָׁלַםִ by the early Hebrew writers, and יְרוּשָׁלַיִם by the later; and signifies *the abode*, or (according to another derivation) *the people of peace*. At present the city is known throughout Western Asia by the Arabic name of *El-kuds*, which signifies 'holiness.' By the Greek and Latin writers it is called Hierosólyma. (Strabo, p. 760; Tacitus, *Hist.* v.)

As the capital city of the Hebrews, and the chief seat of their worship, as well as from its connection with the early history of Christianity, Jerusalem has always been held in great veneration by both Jews and Christians; and, from the same causes, even the Mahommedans regard it with interest and respect. Hence the numerous pilgrimages and travels which have in all ages been made to the holy city, and hence the various contests of the middle ages, between the European Christians and the Moslems, for its possession.

The situation of Jerusalem is rather singular, and offers many advantages, particularly in a military point of view, which were probably considered more than adequate to compensate its disadvantages as the seat of a metropolitan city, for which many think that Samaria offers a preferable situation. But whatever were its advantages or disadvantages, the metropolitan character was fixed to it beyond all possibility of alteration by the foundation there of the only temple for the formal worship of God which the whole country contained.

The site of Jerusalem may be described, with some latitude, as an elevated piece of ground within a basin of enclosing hills. The separation between this spot and the outward borders of its enclosure is well marked by ravines and valleys, except towards the north, where the natural separation of the site from the surrounding country is less noticed. The enclosed platform extends about 1800 yards from north to south, and (in the widest part) 1100 from east to west: it has a general slope from west to east, so that the town is fully displayed, like a panorama, to those who view it from the east. The surface of the platform is uneven, and ends, southward, in the elevated termination so often mentioned in Scripture by the name of Mount Zion. This part is excluded from the modern city, and the ascent to it from the town is not very considerable, although it rises high above the deep external ravine which it overlooks. The other eminences of the platform, such as Mount Moriah (on which the Temple stood), and Mount Acra, are now scarcely distinguishable as elevations, probably from the gradual filling up of the interjacent valleys. Except at Mount Zion the general level of the site is below that of the immediately surrounding country; yet considering that it is not very distant from the sea, its positive elevation above the sea-level is considerable. Of the valleys which surround the city, that to the east, through which lies the course of the torrent Kedron, is usually called the Valley of Jehoshaphat, and abounds in antient and modern sepulchres. Beyond it rises a group of hills, of which the Mount of Olives is the principal, if indeed that denomination does not include them all. The southern valley is narrower, with more abrupt cliffs, and is indeed a rocky ravine, appearing to have been antiently quarried to supply stone for the buildings of the town. Beyond this valley rises a broad and barren hill; while the western valley, which has received the Scriptural names of the Valley of Gihon and of Rephaim, is bounded by a rocky flat, which rises to the north, terminating in a considerable elevation; to this the name of Mount Gihon has been given.

As the interest of the spot arises solely from its antient history, and no remains exist of the buildings which that history mentions as belonging to the period which it embraces, we have been thus particular in noticing the natural characteristics of the place, since they are unchanged, and are often alluded to in the sacred writings and in the histories of the many sieges which Jerusalem has sustained. Some substructions, and the sepulchral excavations in the cliffs around Jerusalem, seem to be all the remains of antient Jewish works which can now be recognised, unless we be disposed to add the sculptured monuments in the valley of Jehoshaphat, which pass under the names of the tombs of Absalom and Zachariah.

In the style of building and arrangement of streets, there is little to distinguish Jerusalem from other walled and stone-built Turkish towns of the same rank. The attention of pilgrims and travellers is chiefly engaged by the sacred places concerning which numberless volumes have been written. There is scarcely any incident mentioned in Scripture, as connected with Jerusalem and its neighbourhood, of which the site is not very distinctly pointed out; but in most instances the authority of such indications cannot but be considered as extremely uncertain. Very ample accounts of all these spots may be found in the works of Cotovicus, Roger, Morison, Surius, Rochetta, and others. In our own language Maundrell supplies a very excellent account, to which the principal additions have been made by Clarke, Buckingham, and Richardson. But the most valuable and trustworthy authority for the dimensions and plan of Jerusalem is the recently published volume of Niebuhr's 'Travels,' Hamburg, 1837.

The Moslems have appropriated the site of Solomon's temple to their own worship. The renowned Sakkara, built by the Khalif Omar, is an octangular structure surmounted by a dome, and stands upon an elevated platform paved with polished marble. This is in the midst of a grand quadrangle (1489 feet by 995), which contains at its southern extremity another mosque, that of El Aksa, which was originally the church by which the Christians distinguished the site of the Jewish Temple. The entire locality is fully described by Dr. Richardson, who obtained the singular privilege of admission to the interior. But to the thousands of Christian pilgrims who yearly visit Jerusalem the great object of interest is the church which contains the alleged sepulchre of Christ, to redeem which from infidel hands was at first the real, and always the ostensible, object of the Crusades. This church was one of the numerous foundations of the empress Helena. As a whole this extensive structure takes a prolonged oblong figure, with irregular extensions in particular parts for the sake of comprehending the various spots connected with the death and burial of Christ; for this church is not only supposed to contain the sepulchre, but the scene of the Crucifixion. The probability of these identifications has however, on very sufficient grounds, been much questioned by some recent travellers. A great part of this church was destroyed by fire about thirty years ago, and has since been restored on the former place, but with inferior materials. The other public buildings of Jerusalem are not of much importance, and do not require particular notice.

Jerusalem, as a whole, is still a respectable looking town; it is of an irregular shape, approaching nearest to that of a square, and is surmounted by a high embattled wall, built of the common stone of the country—a compact limestone. It has seven gates, and is about two miles and a half in circumference. The population of the city has been so variously estimated as to show that it has only been conjectured. Some accounts rate it at 20,000, or even higher; but, from a comparison of estimates and circumstances, we should suppose the Rev. W. Jowett nearest the truth when he states, 'I should think that 15,000 was too high; and should not be very unwilling to rate it at 12,000. In this calculation of course the pilgrims are omitted, who are crowded into the convents, and fill up many spaces which are vacant nine months in the year, augmenting the population by some few thousands.' He supposes that about one-third of the whole are Jews, and that the Moslems are something more than one-third, and the Christians something less.

The history of Abraham mentions that 'Melchizedek, king of Salem,' came forth to meet him when he returned from the slaughter of the kings; and it has generally been supposed that this 'Salem' was the original of the city to which the names of Jebus and Jerusalem were afterwards given. It is more certain, that, when the Israelites entered Canaan, they found the place in the occupation of the Jebusites, a tribe descended from Jebus, a son of Canaan, whose name the city then bore. The lower city was taken and burnt by the children of Judah (*Jud.*, i. 8) after the death of Joshua; but the Jebusites had so strongly fortified themselves in the upper city, on Mount Zion, that they maintained themselves in possession of it till the time of David. That monarch, after his seven years' rule over Judah in Hebron, became king of all Israel, on which he expelled the Jebusites from Mount Zion and made Jerusalem the metropolis of his kingdom. From that time forward there is no city the history of which is more closely connected with that of the people to whom it belonged, and of the country of which it was the capital. For this reason, as well as because of the disproportionate extent which would be given to this article, we do not here notice the numerous details which its particular history embraces. The history of Jerusalem has been given in outline as a part of various works; but we know no complete and separate history besides the 'History von Jerusalem' (down to 1481) of Sebastian Brant (1518). Of the Temple there is a large but not very instructive Arabian history, lately translated into English by Mr. Reynold, under the auspices of the Oriental Translation Society. The Travels of Niebuhr, before referred to, contain a ground-plan of the present city.

JERVIS, JOHN, Earl of St. Vincent, and Admiral of the Fleet, was born at Meaford in Staffordshire, January 9, 1734, O.S.; entered the navy at ten years old; was posted into the Gosport, 40 guns, in 1760; and appointed to the Foudroyant, 80, in 1774. In this ship, which was distinguished for her discipline and effective state, he fought in Keppel's action in 1778; captured the Pégase, French 74, in 1782, for which he received the order of the Bath; and in October of the same year sailed with Lord Howe to the relief of Gibraltar. He was promoted to the rank of rear-admiral, September 24, 1787; and sat in parliament for various boroughs from 1782 until the breaking out of the French Revolutionary war, when he sailed in command of a squadron to reduce the West India Islands, and captured Martinique, Guadaloupe, and St. Lucia. At the end of 1794 sickness drove him home. He was promoted to be Admiral of the Blue, June 1, 1795, and in the autumn took command of the Mediterranean fleet, with which he performed

the great exploit of his life, by intercepting and defeating the Spanish fleet off Cape St. Vincent, in February 14, 1797. The disproportion of force was greater, it is said, than any modern officer had ventured to seek an encounter with, the Spaniards having nearly double our number of ships, and more than double the number of guns and weight of metal. However, Jervis, repeating Rodney's method of breaking the line, gained a complete victory, and captured four sail of the line. In this celebrated engagement the services of Nelson were pre-eminent. The actual loss sustained by the enemy was of less importance than the lustre cast on the British arms by a victory achieved against such odds. Thanks, couched in the most flattering terms, were voted by both houses of parliament; and Sir J. Jervis was raised to the peerage by the title of Earl of St. Vincent and Baron Jervis of Meaford, and received a pension of 3000*l*. Shortly after, his presence of mind and moral courage were severely tried by the breaking out of a branch of the Channel mutiny in his fleet; which however was speedily suppressed by his judicious and decisive severity. Having suffered for some time from ill health, he returned home in 1799; but in April, 1800, took command for a short time of the Channel fleet, on the resignation of Lord Bridport. He was made first Lord of the Admiralty in February, 1801, on the formation of the Addington ministry; and having through life had a sincere dislike of peculation and jobbing, at once set vigorously to cut down extravagant expenditure and to reform abuses. This of course made him very unpopular; and he was accused of rashness, and of crippling the resources of the country by a false economy. Charges of this sort were then very sure to be made against those who exerted themselves to reform old and lucrative abuses. Mr. Pitt partook of the dissatisfaction, and at his return to office, in May, 1804, placed Viscount Melville at the head of the Admiralty. Earl St. Vincent again took command of the Channel fleet in 1806, in Fox's administration, but held it only for a year. His last appearance in parliament appears to have been in 1810, in the debate upon the king's speech, when he spoke strongly in censure of the conduct of the war by ministers. He was appointed Admiral of the Fleet on the day of George IV.th's corronation, July 19, 1821, and died March 15, 1823, in the 90th year of his age. Having no children, the earldom became extinct: but the title of Viscount, by special grant, descended to his nephew Mr. Ricketts. A public monument was erected in honour of him in St. Paul's cathedral.

Earl St. Vincent's professional characteristics were courage, coolness, and decision, amounting almost to sternness of character: these, united with great skill and indefatigable activity, rendered him an admirable officer. He was very independent; and the disposal of his patronage, in which he paid great and unusual consideration to the claims of deserving officers, did him honour.

JESUITS, SOCIETAS JESU, is the name of a celebrated religious order which was formed towards the middle of the sixteenth century. Ignatius or Iñigo Loyola was a Biscayan officer of noble birth, in the Spanish army at the beginning of the reign of Charles V. Being severely wounded in the defence of Pamplona, then besieged by the French and the Navarrese, he underwent a long and tedious confinement previous to his recovery. Loyola was a man of enthusiastic mind; he had been fond of the world, and devoted to gallantry and pleasure; but now, in his forced retirement, he was struck with the precariousness and futility of those pursuits, and he resolved to devote himself to a life of piety and religious labour, for the purpose of reclaiming the minds of his fellow-creatures from vanity and sin. Musing on this subject, he conceived the plan of establishing a religious order, which should be entirely devoted to the four following objects: 1. The education of youth. 2. Preaching, and otherwise instructing grown-up people. 3. Defending the Catholic faith against heretics and unbelievers. 4. Propagating Christianity among the Heathens and other infidels by means of missionaries. Ignatius, having begun to promulgate his views, and to attract attention by preaching against the loose morality of the times, fell under the suspicions of the Inquisition, and was imprisoned, but afterwards released. He then undertook several pilgrimages, and at last repaired to Paris, where he studied and took holy orders. It was at Paris in 1534 that he and six of his friends and fellow-students entered into a solemn compact to promote Loyola's object, the foundation of a new religious order. These first companions and fellow-labourers were Francis Xavier, Lainez, Salmeron, Bobadilla, Rodriguez, and Le Fevre. They were afterwards joined by three more: Lejay, Codur, and Brouet. Ignatius with his friends repaired to Rome in 1537, where he laid before Pope Paul III. an outline of the institutions and regulations of his intended order. Loyola had been a military man, and he based his rules upon the principle of a strict subordination, carried through several gradations, terminating with the præpositus generalis, or general superior, who was to have absolute sway over the whole Society, and from whose decisions there was to be no appeal. The general was to be subject to the pope only. Most of the old monastic orders had a considerable share of democracy in their institutions they assembled in chapters and elected their local superiors, and decided upon other questions concerning their community by a majority of votes, and although they had also their respective generals residing at Rome, yet their authority over the distant convents of the various provinces was very limited. Their chapters occurred frequently, and their generals and provincials were mostly changed every three years. All this gave them something of a popular character· they had their canvassings for elections, their personal ambition, and intrigues. But Loyola's projected order was strictly monarchical, and therefore adapted to be a more effective support to the Roman see, at a time when support was most wanted in consequence of the spreading of the Reformation. Besides this, the wealthier of the monastic orders, such as the Benedictines, employed their leisure in scientific and speculative studies, living retired and knowing little of political affairs; and the mendicant orders, or friars, had degenerated from their first zeal, and had become obnoxious by the sale of indulgences, and despised for their corruption, ignorance and vulgarity. The prelates of the court of Rome, such as Bembo and Leo X. himself, spoke with open scorn of the friars, and called them hypocrites. Another advantage of the proposed constitution for the Jesuits was, that they were not bound to keep canonical hours in the choir like other monks, and therefore had more uninterrupted leisure for study or business.

Pope Paul III., after deliberating with his cardinals, some of whom were not favorable to Loyola's plan, approved of it, and it was decided that the new order should be called the Society of Jesus, that the members should wear no monkish garb, but dress in black, like the secular priests, and should in fact differ essentially from the monastic orders then existing. The bull of the pope authorizing the new Society was issued in 1540, and in it, by a remarkable privilege, the general of the Jesuits was authorized to issue such regulations as he judged fit, and to alter the existing ones according to time, place, and circumstances. The original 'Constitutiones' of Ignatius were written in Spanish, but afterwards translated into Latin. The first edition of them appeared at Rome, 'Constitutiones Societatis Jesu,' 1558, after the death of the founder, who expired on the 31st July, 1556. He left also a mystical treatise called 'Exercitia Spiritualia.' At his death the Society was already established in Italy, Spain, Portugal, and Germany, and had above one hundred schools, besides numerous missionaries in the East and in Africa and America. Ignatius was succeeded as general of the Society by James Lainez, a man of more extensive information and greater elasticity of character than his predecessor. It is to Lainez that the principal share in framing the 'Constitutiones' is attributed, and that work bears the impress of a master mind. Cardinal Richelieu said that it was a model of administrative policy. The Constitutiones are divided into ten parts, subdivided into chapters. Part i., 'De admissione ad probationem,' concerns the mode of admission of applicants for the noviciate; the qualifications required in the applicant, such as health, no grievous deformity or mutilation, or other physical imperfection; certificates of good conduct and temper, natural abilities, and fourteen years of age complete. Birth, wealth, and other accidental circumstances are to be considered as null where the physical and mental qualifications fail; but should they be united with these in the same individual, they render him more acceptable. Then comes a list of absolute impediments to admission, such as having committed murder, apostacy, and other grievous offences, having been subjected to a degrading sentence, having belonged to some monastic order, being married, and lastly, labouring under insanity or decided weakness of intellect. Defects of temper, obstinacy, injudicious enthu-

siasm or visionary devotion, being involved in debt and other civil ties, are not absolute impediments, but the consideration of them is left to the discretion of the general or of any of his subordinates, to whom he may give the power of admitting probationary pupils. The candidate, if approved of, is admitted to a first probation, as a sort of guest for a few weeks in one of the houses of the Society, in order that he may become acquainted with the mode of living. He afterwards assumes the dress of the order, and is examined by proper examiners upon the numerous points contained in the printed form, *Primum ac Generale Examen iis omnibus qui in Societatem Jesu admitti petunt proponendum*, Rome, 1558. Should the examination prove satisfactory, the applicant is shown the constitutions and regulations of the Society; and after, confessing himself and receiving the sacrament, he signs a declaration that he will observe the rules and discipline thereof, and he is then admitted into one of the houses of second probation, or noviciate. Part ii., 'Quæ ad eos dimittendos pertinet, qui ad probationem admissi fuerunt et parum apti ad Societatem inveniuntur.' Those who during their noviciate are found, after mature experience, not to be fit subjects for the Society, on account of mental or bodily defects or vices, are to be dismissed privately, without scandal or exposure, and with kind advice and exhortations. Those who leave of their own accord are not to be sought after, unless they have qualities which make it desirable for the Society to retain them. Part iii., 'De iis conservandis et promovendis qui in probatione manent.' This part treats of the mental and moral discipline to which novices are subject; docility and obedience are to be inculcated, pride and obstinacy to be conquered: it treats also of the physical education, cleanliness, wholesome diet, proper exercise, &c. The term of probation lasts generally two years. Part iv., 'De iis qui in Societate retinentur instruendis in literis.' This part treats of the colleges and schools. The colleges have revenues derived from donations or bequests of benevolent persons; those colleges which can support twelve scholars besides teachers are not to collect alms or receive other eleemosynary offerings. After two years' probation, those who intend to enter the Society are received as scholastici in one of the colleges, and take the vows of chastity, poverty, and obedience. The courses are humanities and rhetoric, logic, natural and moral philosophy, metaphysics, and theology (both scholastic, and positive or dogmatic) and the study of the Scriptures. Besides the colleges or seminaries for the Society, there are classes and schools for lay or external pupils. Every college is under the direction of a rector, appointed by the general or by the respective provincials, and chosen from the class of coadjutors, and removable at pleasure. The Christian doctrine or Catechism is to be read and explained by the rector. Subsequent regulations were published at various times concerning the mode of instruction in the 'Ratio Studiorum' of Acquaviva, and the 'Methodus Docendi et Discendi a P. Juvencio in usum Magistrorum Societatis Jesu,' which was approved of by the 14th general congregation of the Society. Another chapter treats of the universities which belong, or may belong, to the Society; of the faculties of arts, philosophy, and theology; of the examinations and degrees, &c. The Society did not concern itself with the faculties of law and medicine. Part v., 'De iis quæ ad admittendum in corpus Societatis pertinent,' treats of the admission of scholars into the body of the Society, either as professi or coadjutors. The professi must have studied theology for four years, and be past twenty-five years of age. The formula of the profession is given. The vows taken on making profession before the reverend father-general, 'locum dei tenenti,' or any other superior appointed by him, are perpetual chastity, poverty, obedience, and a peculiar care of the education of youth; besides which the professi promise an especial obedience to the sovereign pontiff with respect to any missions which he may send them to. This last promise, or vow, is not made by the coadjutors. Part vi., 'De iis qui admissi et in corpus Societatis cooptati sunt, quod ad ipsorum personas attinet,' gives regulations for the manner of living in the professed houses, which, unlike the colleges, cannot have any property or settled income, but the inmate must live upon the alms given by the faithful. The coadjutors who are not employed in the colleges as rectors or teachers must live in the professed houses of charity, like the professi. The professi and the coadjutors must renounce all claims to hereditary succession, nor can the Society succeed to any of their claims. But there were also lay or secular coadjutors, who took the simple vows, yet continued to enjoy their property, and lived in the world at large. Part viii., 'De iis quæ pertinent ad admissos in corpus Societatis, ad proximorum utilitatem, in vineam Domini distribuendos,' treats of the various kinds of missionaries, those sent by order of the Pope, and those sent by the general of the society, and gives them directions, &c. Part viii., 'De iis quæ conferunt ad eorum qui dispersi sunt cum suo capite, et inter se, mutuam unionem,' recommends frequent reports and correspondence between the rectors and provincials and the general, and between the missionaries and other detached fathers with their respective provincials or other superior, &c. Every member of the Society is to report to his immediate superior any misconduct which he observes in any of his companions. The general receives monthly reports from the provincials, and quarterly ones from the superiors of professed houses, the rectors of colleges, &c. These reports contain notes on the disposition, capacities, and conduct of the individual members, besides news and occurrences which may affect or interest the body of the Society or any part of it. The second chapter of this part treats of the general congregations or representative assemblies of the Society; and it begins by saying, that owing to the regular and constant intercourse and correspondence kept up between the general and the local superiors, the trouble and confusion attending such general assemblies can be in great measure avoided, and they can only be necessary either for the purpose of electing a new general or for deliberating on some very weighty matter concerning the Society, such as the dissolution or transfer of its houses and colleges, &c. In the first case each province deputes its provincial and two more professed members, who are chosen by a provincial congregation, convoked for this special purpose, which provincial congregation consists of all the professi of the province who can conveniently attend, and those coadjutors who are rectors of colleges. In the second case, for purposes of deliberation, the father provincial appoints two of his subordinates, and the general may add some others, making not more than five deputies altogether, for each province. Part ix., 'De iis quæ ad caput Societatis et gubernationem ab eo descendentem pertinent,' concerns the qualifications, powers, and duties of the Præpositus Generalis. The general is for life, resides at Rome, is attended by a monitor and five assistants. From his orders there is no appeal: all are obliged to obey him unhesitatingly; he may expel members, or remove them wherever he pleases, inflict punishments, issue regulations, or alter the existing ones. His power is in fact absolute. Part x., 'De modo quo conservari et augeri totum corpus Societatis in suo bono statu possit,' contains advice to all and each of the various classes and members, recommending strict discipline, obedience, zealous teaching and preaching; not to seek after dignities or honours, and even to refuse them unless obliged by the Pope; strict morality, moderation in bodily and mental labour, brotherly charity, &c.

Lainez, being sent by the pope as his legate to the Council of Trent, was one of the chief advocates of the papal supremacy, and maintained, among other things, against the opinion of the archbishop of Granada and other Spanish prelates, that the jurisdiction of the bishops and their authority over any particular diocese is entirely derived from the pope, who is the fountain-head of all ecclesiastical authority, and that he can give it or suspend it, or transfer it when he sees fit. Lainez repaired also to the Conference of Poissy, in 1561, where he had to face Beza, and other Calvinist theologians, but his arguments, mixed with coarse vituperations against his antagonists, according to the polemics of the age, produced little effect. About the same time the Society, by the influence of the Cardinal de Lorraine, and after several years' struggle against the university of Paris and the Bishop du Belley, obtained letters patent from Francis II. to open colleges and schools in France. The Jesuits taught gratis, and the university, whose courses of lectures were paid for, was jealous of them, and attacked them repeatedly before the Parliament as an institution contrary to the laws and dangerous to the state. But this being the time of the great religious and civil war in France, the belief, says De Thou, that the Jesuits were born to conquer and destroy Protestantism, made the Parliament and the French prelates wink at their introduction into the kingdom, at least until further deliberation. William Duprat, bishop of Clermont, son of the Chancellor Duprat,

gave them a house in Paris which they made into a college, called the College of Clermont, and he bequeathed them also 36,000 écus in his will.

During the war of the League the Jesuits, like the other monastic orders, with the Sorbonne, and the Parliament of Paris, showed themselves opposed to the claims of Henri IV. as being a heretic. Even after the abjuration of that prince a fanatic of low birth, called Barrière, conspired to murder him, but was discovered, and it was found that a Capuchin, a Carmelite monk, a curate, and a Jesuit rector of the college at Paris were cognizant of and accessory to the conspiracy. Soon after another fanatic, Jean Chatel, attempted his life, and actually wounded Henri. This young man had studied under the Jesuits, but it was never proved that they had instigated him to the deed. It is true that among the papers of a Jesuit called Guignard some satirical and abusive expressions against the king were found, which seemed to imply an approbation of the crime. Chatel was broken on the wheel, and Guignard was hanged; and the Parliament of Paris, already instigated against the Jesuits by the university, decreed their banishment in 1594, which sentence however did not extend to the jurisdictions of the parliaments of Bordeaux and Toulouse. But at the end of 1603 Henri IV., at the pressing request of the pope, recalled the Jesuits, saying to the president, De Harlay, who remonstrated against this measure, that 'the Jesuits ought no longer to be charged with the crimes of the League, which were the error of the times; and as every state thought them useful in the education of youth, he should not shut the door against them, especially as he would not appear to mistrust his own born subjects.' On the 2nd of January, 1604, the parliament of Paris registered the king's letters patent for the restoration of the Jesuits. From that time they remained in France, where they greatly extended the number of their colleges and pupils, though always seen with a jealous eye by many, till their final expulsion in 1764. Their disputes with the Jansenists, which were carried on with great bitterness on both sides, are mentioned in the articles ARNAULD and JANSENISTS.

The Jesuits found their way into England under Elizabeth, in whose reign several of them were implicated in conspiracies against the queen, for which they were executed. It ought to be noticed however, that De Thou, who is no friend to the Society, states that the conspirator Parry, who is said to have been encouraged in his attempt by a Venetian Jesuit, met at Paris the Jesuit Vatz, who earnestly dissuaded him from his purpose, quoting the opinions of other learned men of the Society, who declared that no reason, political or religious, could justify an attempt against the life of a sovereign, however heretical. This and other similar instances prove that in so numerous a body as that of the Jesuits' society men of various tempers and opinions must be found, some of whom, through a strained casuistry or fanatical zeal, arrived at totally different conclusions from those of the more sober and more honest part of their community.

In the reign of James I. the Jesuit Garnet was tried for having participated in the Gunpowder Plot; and after exhibiting throughout his examination a great aptitude for equivocation, he was condemned and executed. A full investigation of this curious trial is given in vol. ii. of the 'Criminal Trials,' published by the Society for the Diffusion of Useful Knowledge.

The missions of the Jesuits form an important part of the history of their Society. The first attempts by Xavier were premature. He had more zeal than information, and the accounts of his numerous conversions ought to be received with caution. The arms of the Portuguese effected more conversions by force in India than Xavier's persuasion, who himself confesses that he could not understand nor be understood by the natives, though he could baptize them. In Japan, where he went unprotected by a Portuguese force, he failed; but he served as a pioneer to prepare the way for others better qualified for the task, and the Jesuits formed in time numerous Christian congregations in Japan. The history of the Japanese Christians, and their extermination in 1637, is found in Bartoli, *Historia della Compagnia di Gesu*, 'Il Giappone, seconda parte dell' Asia;' and it forms a narrative of considerable interest, written apparently with great simplicity. The author does not disguise the faults committed by the Christians, which contributed to their ruin.

In China the Jesuits were likewise successful, and their establishment there has been more durable. Bartoli, in another part of the same work, 'La Cina, terza parte dell' Asia,' gives an account of their settlement in that empire, and of their progress; and further information is found in the 'Lettres Edifiantes et Curieuses.' [HALDE, DU.] Between the years 1581 and 1681, one hundred and twenty-six European Jesuits were employed in the missions of China, many of them men of information, to whom Europe is indebted for the first authentic information respecting the internal condition of that vast empire. The generals of the Society chose men acquainted with mathematical and mechanical sciences, which they knew were in request at Pekin, and thus they obtained a footing and an influence at the emperor's court which no other Europeans have ever acquired. Although persecutions burst out against the Christians of China, yet the Jesuits never entirely lost their hold there, and their house at Pekin has continued to exist till our own times. [AMIOT, LE PERE.]

From India Jesuit missionaries found their way into Abyssinia, where Portuguese travellers had penetrated many years before [ALVAREZ], but the Jesuits went farther into the country, especially in its southern parts, than any other Europeans, either before or after them. Paez and Lobo visited the sources of the Bahr el Azrek, or Abyssinian Nile, and Father Fernandez proceeded as far as Narea, about 8° N. lat. [TELLEZ.]

In Paraguay the Jesuits had an open field for the display of their abilities and principles. Their missionaries went to South America after the country had been devastated by the Spanish conquerors, who hunted the Indians like wild beasts. The Jesuits judged that the poor natives might be converted by milder means, and be made Christians and happy at the same time. They obtained from the court of Spain a declaration that all their Indian proselytes should be considered free-men, and that the Jesuits should have the government of the communities of converts which they should form in the interior of the country. And the Jesuits did form a flourishing community of Indian converts on the banks of the Paraguay and the Parana, who are said to have amounted to between one and two hundred thousand, and they governed them for a century and a half in peace and happiness, keeping them in the condition of docile but contented pupils, directing their labours, and instructing them in the useful arts, but not in the refinements or luxuries of Europe. There were no taxes or law-suits in Paraguay; each able-bodied man had a moderate task to perform, and the produce of their common labour provided for the wants of all. Writers of very different opinions, Raynal, Montesquieu, Robertson, Muratori, Southey, and others, have done justice to the paternal administration of the Jesuits in Paraguay.

Other accounts of that remarkable colony are found in numerous works, in the 'Letters from Paraguay,' in the various histories of the 'Jesuits' Missions,' &c. And it is a remarkable instance of political injustice, that the very benefits which the Jesuits were imparting to mankind in South America should have been made the cause or pretext for their ruin. In 1750, Spain, by a treaty with Portugal, thought proper to give up seven districts of Paraguay to the latter power, in exchange for a territory which the Portuguese had occupied on the left bank of the river La Plata, and the Spanish government ordered the Jesuits and their Indian pupils to abandon their homes and remove to some other part of the Spanish territories. The fathers in vain remonstrated against the injustice and cruelty of expelling men from the fields which they had by their labour reclaimed from the wilderness; the harsh mandate was repeated, and the Jesuits were prepared to obey. But the natives refused to submit, and resisted the Portuguese and Spanish forces which were sent against them, and although a subsequent change in the diplomatic relations of the two countries left the Indians in possession of their country, yet the Jesuits were falsely accused of having encouraged what was styled the rebellion. The Spanish government, after mature investigation, acquitted them, but the Portuguese minister Pombal, a harsh and unprincipled man, believed or affected to believe in the rebellious spirit of the fathers, whom he wished to expel from Portugal, because he was jealous of their influence, and had found them repeatedly in the way of his plans and schemes at home. An attempt by some noblemen to murder the king, Joseph of Portugal, was charged upon the Jesuits, because Father Malagrida, one of the Society, was the confessor of some of the guilty.

As proof however could not be obtained against him, Father Malagrida was accused of heresy, on account of some ascetic visionary works which he had published, was condemned by the Inquisition, and executed; and in September, 1759, the minister, in the king's name, gave an order for the expulsion of the Society from the Portuguese territories and for the confiscation of their property. The order was executed with the greatest inhumanity both in Portugal and Brazil, the fathers being shipped off with indecent hurry, like so many cattle, on board ships bound for Italy, where they were landed in a state of utter destitution.

France followed next in the same course of proscription. The Jesuits had made themselves many enemies in that country by their long and bitter persecution of the Jansenists, and their controversies with that sect had brought much obloquy upon their institutions and moral principles. [JANSENISM.] Pascal, in his 'Lettres Provinciales,' had assailed them with ridicule, which has always proved most powerful in France. The parliament of Paris felt an old and hereditary hostility towards them: the minister Choiseul disliked them on personal and political grounds; he had felt and ascertained that their secret influence could often thwart and balance the credit of any minister; besides which, Choiseul was partial in a certain degree to some of the free-thinking philosophers of his time, who had no sympathy for the Society. To crown all, even the king's mistress, Madame de Pompadour, arrayed herself against the Jesuits. That intriguing woman wished to remain at court under some more decorous name than that of concubine to Louis XV. She solicited the appointment of lady of honour to the queen, and in order to strengthen her application she chose for her confessor Father De Sacy, a Jesuit who had a reputation for exemplary conduct. She pretended that she had dropped all intercourse with the king, and that she was really penitent. De Sacy however did not allow of any equivocation: he told the lady that if her penitence were sincere, she must quit the court altogether, as La Vallière had done under Louis XIV. The result may be easily guessed. Madame de Pompadour left the too rigid Jesuit, remained at court, and from that moment became a declared enemy to the order. Thus the strict morality of a member of that Society, which has been often charged with being too lax and accommodating, contributed to its ruin. A pretence soon occurred for effecting it. Father Lavalette, who was at the head of the missions in the French West Indies, had been speculating in colonial produce. His cargoes were seized by the English, then at war with France. Father Lavalette became a bankrupt for 3,000,000 livres. His creditors in France appealed to the parliament of Paris, which, having seen in the constitutions of the Society that no individual belonging to it could possess property on his own account, considered Father Lavalette's debt as that of the whole body, and condemned the Society to pay the creditors. An immense outcry was raised against the Jesuits, and the parliament in 1762 declared that an independent body like the Society, having peculiar laws, and being all subject to one individual residing at Rome, was an institution dangerous and unfit for any well regulated state; the other parliaments made similar declarations, and the partisans of the Jansenists, the philosophers, the courtiers, and the minister, all echoed the denunciation. At last, in 1764, by an order of the king, the Society was entirely suppressed in France, and their property was confiscated; but a small pension was given to the members, who were allowed to remain dispersed in the country, on condition of swearing to renounce the Society and its institutions.

Their fall in Spain took place three years later. Choiseul is said to have contributed to it by persuading the honest but credulous Charles III. that an insurrection which broke out at Madrid in 1766 against the minister of the day was the work of the Jesuits. D'Aranda, the president of the council of Castile, already prepossessed against the Society, was the confidant of King Charles in affecting their expulsion. The Society was feared, perhaps more than there was need, and everything was planned against them with the greatest secrecy. The king with his own hand wrote letters to all the governors of provinces throughout the Spanish monarchy in Europe and in the colonies, which were not to be opened until a specified day and in a specified place. When the appointed time came, the 31st of March, 1767, the colleges and houses of the Jesuits throughout Spain were surrounded at midnight by troops, sentinels were posted at every door, the bells were secured, and king's commissioners having roused and assembled the respective communities in the refectory, read to them aloud the royal decree which expelled them from Spain. The members, having taken their breviaries, some linen, and a few other conveniences, were placed in carriages and escorted by cavalry to the coast, where they embarked for Italy. After being refused admittance in several harbours, and kept for some months on board crowded ships, during which many of the aged and infirm died, the survivors were at last landed in Corsica.

Similar measures were executed in Spanish America, only with circumstances of still greater harshness. In Paraguay the Indians were amazed and distracted at the news, and would have opposed by force the execution of the decree, but here the fathers gave a noble example of fortitude and resignation, which was an answer to all former charges brought against their Society. These men, represented as so ambitious, so worldly, so intriguing, so refractory towards the civil power—these men, who in Paraguay at least possessed an unbounded influence over their flocks, exerted all that influence to appease the enraged Indians, and to induce them to submit quietly to the royal decree. No more than 9000 dollars, about 2000*l.* sterling, were found in their coffers.

By a compromise between the pope and the king of Spain, the latter allowed a pension of a shilling a day to the expelled fathers; but on condition that no apology of any sort should be written by any member of the order, under pain of all losing their pensions.

In the following year, 1768, the king of the two Sicilies and the duke of Parma suppressed the Jesuits' Society in their dominions. It still continued in the Sardinian and the Papal states; but in February, 1769, their supporter Clement XIII. died, and Ganganelli was elected in his stead. France, Spain, Portugal, Naples, all insisted, in very strong terms, on the final suppression of the Society by the new pope. Ganganelli proceeded with caution; he took three years to consider the matter. He appointed a congregation of five cardinals to examine the charges brought against the Society. At last, on the 21st of July, 1773, the pope issued a bull, in which, after descanting on the laudable object of the founders of the Society, and on the services it had rendered to religion, he observed that on many occasions a spirit of discord had broken out between them and the other ecclesiastical authorities, that many serious charges had been brought forward against individual members, who seemed to have deviated from the original spirit of their institutions, that, lastly, most Catholic princes had found it necessary for the peace of their dominions to expel the Jesuits therefrom, and that now, for the peace of the Christian world, and being moved by the most weighty considerations, and considering that the Society of Jesus could no longer bring forth those fruits of piety and edification for which it was intended, he declared the said Society to be suppressed and extinct, its statutes annulled, and its members who had been ordained priests to be considered as secular priests, and the rest to be entirely released from their vows. He allowed those professed members who were old and infirm, to remain in the houses of the extinct Society, but merely as guests, without interfering in their future management, which was entrusted to commissioners.

In consequence of this bull, the Jesuits were likewise suppressed in the Sardinian monarchy, in the Austrian dominions, and in every Catholic state. Two powers only, Prussia and Russia, one Protestant and the other Greek schismatic, allowed the fathers an asylum in their dominions, and continued to entrust them with the education of their Catholic subjects.

At the time of the first expulsion of the Jesuits from Portugal, in 1759, the Society reckoned altogether 22,589 members, half of whom were priests. They had 24 professed houses, 669 colleges, 176 seminaries, or boarding-houses, 61 noviciate houses, 335 residences, and 273 missions. Their principal professed house, in which the general resided, was a vast building attached to the splendid church of the Gesù at Rome. They had besides the Roman college and church of St. Ignatius in the same capital, several other colleges and seminaries for boarders of various nations, a noviciate house on the Quirinal, a seminary and college at Frascati, a house at Tivoli, and numerous other colleges and schools in the Papal states. All these, after the suppression of the Society, were entrusted to secular priests

and professors, but still the method and the discipline of the Society were in most instances continued, being found too useful to be abrogated.

The general of the Society, Father Ricci, was confined in the castle of St. Angelo, being suspected of still assuming in secret his former authority over the dispersed Jesuits, and also, but apparently without foundation, of having concealed sums belonging to the Society. Nothing however having transpired against him, he was treated with some courtesy and attention, but was kept in confinement till his death, in November, 1775. On his death-bed, before receiving the sacrament, he signed a solemn though mild protest on behalf of the extinct Society, the conduct of which, he said, to the best of his knowledge, had not afforded grounds for its suppression, nor had he himself given any reason for his imprisonment: he ended by forgiving sincerely all those who had contributed to both. His remains were buried with all due honour in the church of the Gesù, among those of his predecessors.

After the Society had been suppressed for about 30 years, several attempts were made at the beginning of the present century to re-establish it. Many persons in high stations, frightened at the convulsions which agitated the world, imagined that had the Jesuits continued they might have proved a powerful means for maintaining order and preventing revolutions by the moral influence which they had over youth. In 1801, Pius VII. issued a brief, allowing the Jesuits of Russia to live as a Society, and to have colleges and schools. Another brief, dated 30th July, 1804, allowed, at the request of king Ferdinand of Naples, the opening of schools and colleges by the Jesuits in the kingdom of the Two Sicilies. Lastly, after his restoration, Pius VII. issued a bull, in August, 1814, solemnly re establishing the Society as a religious order, under the constitutions of St. Ignatius, and under obedience to the general chosen by it, to be employed in educating youth in any country of which the sovereign shall have previously recalled or consented to receive them; and Pius began by restoring to them their house of the Gesù, and afterwards the Roman college. The Jesuits have colleges now also in the Sardinian states, in Modena, and in the kingdom of the Two Sicilies, and likewise at Freyburg in Switzerland, where they have a fine college, attended by pupils from France and other countries. In France they had re-introduced themselves in a kind of clandestine manner after the Restoration, upon which a great outcry was raised, and they were finally expelled in 1830. Both the expectations of their friends and the fears of their enemies appear to have been exaggerated, as circumstances have changed too much in Europe to allow the Jesuits to resume anything like their former influence. In Spain Ferdinand restored them, but after his death the populace of Madrid, excited by the declamations of the ultra-liberals against the monks, took it into their heads, during the prevalence of the cholera, that the Jesuits and other monks had poisoned the springs. Under the influence of this delusion they repaired to the convents, and particularly to that of the Jesuits, and murdered the inmates in their cells. Since that time the legislature has suppressed all monastic institutions in Spain.

In Russia the Jesuits were expelled by a ukase of the emperor Alexander, in June, 1817, upon the charge of intriguing and of making proselytes among the members of the established Greek church.

The act of the 10th Geo. IV., c. 7, which is entitled 'An Act for the Relief of his Majesty's Roman Catholic subjects,' forbids Jesuits, or members of other religious orders, communities, or societies of the Church of Rome, bound by monastic or religious vows, from coming into the realm, under pain of being banished from it for life; except natural born subjects, who were out of the realm at the time of the passing of the act. Such religious persons may however enter the United Kingdom on obtaining a licence in writing from one of the principal secretaries of state, who is a Protestant, and may stay such time as such secretary shall permit, not exceeding six months, unless the licence is revoked before the end of the six months. The act also makes it a misdemeanor in any Jesuit, or member of other religious body described in the act, to admit, or to aid in or consent to the admission of, any person within the United Kingdom to be a member of such body; and any person admitted or becoming a Jesuit, or member of other such body within the United Kingdom, shall, upon conviction, be banished from the United Kingdom for life. It is however provided that nothing in this act shall affect any religious order, community, or establishment consisting of females bound by religious or monastic vows.

Of the bitter polemics and the multifarious charges against the Jesuits we have not space here to speak at any length, but we will refer our readers to the principal works among a most voluminous mass of writings, both in attack and defence of the Society. The polemical works on this subject are innumerable, but a good history of the Jesuits is still wanted. The 'Histoire Générale des Jésuites,' by La Coudrette, is a work of considerable research and extensive information, but the author was a party writer against the Society; and his own assertions, whenever they are not supported by authentic proofs, must not be implicitly trusted. 2. The famous 'Lettres Provinciales,' by Pascal, had great success at the time, but the charges which he brought against the Jesuits, though founded upon the notions of some individual casuists belonging to the order, cannot in fairness bear against the body of the Society, which did not countenance their extravagant doctrines. Voltaire himself, no friend to the Jesuits, acknowledged this; and Father Daniel, in his 'Entretiens de Cléandre et d'Eudoxe,' has refuted most of Pascal's arguments. 3. Arnauld, a polemical writer of the Jansenists' party, wrote 'La Morale Pratique des Jésuites,' in which also charges against individuals are construed into general charges against the whole Society, and some real facts and documents are mixed up with party bitterness and exaggeration. 4. 'Extrait des Assertions dangereuses et pernicieuses en tout genre que les soidisant Jésuites ont, dans tous les tems, perseveramment soutenues, enseignées, et publiées dans leurs livres, avec approbation des Supérieurs et Généraux.' This book seems to come directly to the purpose by appealing to numerous passages extracted from Jesuit writers. But then there is a 'Réponse aux Assertions,' in 3 vols. 4to., 1763, in which the author of the previous work is charged with no less than 758 falsifications and alterations of the texts quoted by him, and the advocate of the Jesuits produces in every instance the original text and confronts it with the corresponding one in the assertions. In order to judge correctly one ought to refer to the original works. These are the most weighty authorities against the Jesuits. Among the defenders of the Society must be mentioned 'Apologie de l'Institut des Jésuites,' 2 vols. 8vo., which is a standard work in their defence. Numerous declamatory works and satirical pamphlets have been published against the Society, most of which are contemptible in point of argument. The famous 'Monita Secreta,' or pretended private instructions given to the higher and most tried members of the order, are now generally acknowledged to be spurious. The more substantial charges brought against the Society may be classed under the following heads:—1. Antisocial and immoral principles found in some works of Jesuit casuists, such as Escobar, Mariana, Sanchez, Bauny, Busenbaum, &c. It does not appear however that the Jesuits in general, either individually or as a body, acted upon these obnoxious principles, which, on the contrary, were censured and repudiated by the Society. The doctrines of their most illustrious moralists, of Father Bourdaloue, of Cardinal Sforza Pallavicino, of Bellarmino, and others, are free from such stains. 2. General latitudinarianism in the ethics and moral practice of the Jesuits, not so much with regard to their own conduct, which, with very few individual exceptions, is acknowledged to have been pure and freer from scandal than that of most other monastic orders, but with regard to the lay persons whose consciences they directed, or to their proselytes in distant countries, such as China, where they are accused of winking at several superstitious and idolatrous practices among the new converts, and for which they were in fact censured by the pope himself. [CLEMENT XI.] Their doctrine of probabilism, their attaching too great an importance to the merit of good works, and their bias towards casuistry and equivocation, have been often animadverted upon. 3. Great ambition of ruling over the consciences of the people. The institutions and practice of the Society certainly tended to keep the world in subjection, by means of early discipline and persuasion, to the spiritual authority of the Roman Catholic church, and to the temporal authority of the respective sovereigns. That this should have excited the animosity of those who dissented from that church, of which the Jesuits were the firmest support—that the Protestants for instance should have had no friendly feeling for their

most formidable enemies, is nothing surprising or unreasonable; that the free-thinking philosophers of the eighteenth century, who railed at Christianity altogether, should have railed at the Jesuits, was a thing to be expected, as well as that persons of democratic feelings, or who wished to introduce the popular element into the constitutions of the European states, and who advocated an individual liberty of thought and action, should have rejoiced at the fall of the Society; and lastly, that the Jansenists, whose principles of ethics and whose notions of ecclesiastical discipline differed totally from those of the Jesuits, should have had frequent and bitter quarrels with the latter, is not surprising,—but that sincere Roman Catholics, priests, monks, bishops, and cardinals, and, lastly, a pope himself, should have aimed at and effected the destruction of an order which asserted the duty of subjection to the pope; that absolute Catholic monarchs should have proscribed the Jesuits, whose precepts tended to keep the people docile and obedient to the temporal power,—this is a singularity which must strike every dispassionate observer of the events of the eighteenth century, and which can only be accounted for by the agency of a variety of remote or hidden causes, and of personal passions and momentary interests which often prevail in the councils of princes. The Jesuits made proselytes; but this was in conformity to the spirit and received practice of their church: they preached perfect obedience to the decisions of that church and of its head the pope; but in doing this they followed the established Roman Catholic doctrine. Bossuet, who was no Jesuit, defines 'a heretic to be one who has his own opinion, and follows his own judgment and sentiment in matters of religion; while a Catholic, on the contrary, adopts without hesitation the opinion of the church.' And the Jesuits acted and taught in conformity with this principle.

It is true that the Jesuits' notions of papal authority went farther than those of the Gallican church, but it is also true that the provincials of the Jesuits in France and all their subordinates in that kingdom recognised in solemn instruments the civil independence of the sovereign, and that the four articles of the Gallican church were taught in all the schools of the French Jesuits; and in the year 1761 the French Jesuits signed and transmitted to the chancellor Lamoignon a declaration to the effect—'1. That they held and professed that in no circumstance or place, under no pretence of tyranny or vexation, on no account of religion, is it lawful for any person, whatever be his state or condition, to make any attempt, directly or indirectly, against the person of sovereigns, or to insinuate or favour any act that can tend to endanger their safety, and that they condemn and detest as execrable any doctrine to the contrary which may be found in any works that may have been composed, either by any member of the Society, or by any other person. 2. They hold and profess the doctrine of the clergy of France declared in their Assembly of 1682, and that consequently they will always teach that the power given to St. Peter, to his successors, and to the church itself, is purely spiritual, and that they have no power over anything that concerns temporals. 3. That they will always be subject to the laws, ordinances, regulations, and usages of the kingdom, in the same manner as all other subjects of the king; and that they will not attempt anything contrary to the rights of the bishops, curates, and universities, or make any use of any privilege, whatever it may be, except in so far as it is conformable to the import of the laws and maxims of the kingdom. 4. That if it should happen (which may God forbid) that they should be ordered by their general, or by any other person invested with any authority, to do anything contrary to the laws of the church or the state, to their duty to their sovereigns, or to the public welfare or tranquillity, they declare that they hold and ever will hold such decrees or orders to be null, and consider themselves obliged to disobey them.' (*Réponse aux Assertions*, vol. iii., p. 597.) Still as these were not the original principles of the Society, nor conformable to the spirit of its constitutions, and as it could not be expected that they would be assented to by the Society at large, the suspicions engendered in the minds of sovereigns and their ministers certainly contributed to the downfall of the Jesuits. Their devotion to the pope injured them with the sovereigns, and then the sovereigns induced a pope to forsake them also. The other monastic orders were jealous of them, and the bishops and parochial clergy disliked them as too independent a body. It ought also to be observed that the Jesuits, though professing to be devoted subjects to the Roman see, were not always very manageable subjects, and that several popes, Clement XI., Innocent XI., Innocent XIII., and Benedict XIII. found them at times refractory. They were in reality too powerful even for the pope to meddle with.

A fresh charge against the Jesuits was their accumulating riches, and such suspicion probably stimulated the zeal of several ministers and courtiers against them; but the fact is, that at the suppression of their order, after the most minute inquisition, no treasures were found, no hoarded funds: several of the houses and colleges were encumbered with debts, and the expelled members of the Society lived the rest of their days in a state bordering upon indigence.

During two centuries and a quarter which elapsed from their foundation to their suppression, the Jesuits rendered great services to education, literature, and the sciences. Throughout all Roman Catholic states they may be said to have established the first rational system of college education. Other orders, such as the Fathers of the Christian Doctrine, instituted in 1571, the Clerici Scholarum Piarum, in 1617, and the Brothers of the Christian Schools, or Ignorantins, in 1679, applied themselves more especially to the elementary education of children, though the Jesuits also did not altogether neglect this branch. The colleges of the Jesuits were equally open to the noble and the plebeian, the wealthy and the poor: all were subject to the same discipline, received the same instruction, partook of the same plain but wholesome diet, might attain the same rewards, and were subject to the same punishments. In the school, the refectory, or the play-garden of a Jesuit's college, no one could have distinguished the son of a duke from the son of a peasant. The manners of the Jesuits were singularly pleasing, urbane, and courteous, far removed from pedantry, moroseness, or affectation. Their pupils, generally speaking, contracted a lasting attachment for their masters. At the time of their suppression the grief of the youths of the various colleges at separating from their teachers was universal and truly affecting. Most of the distinguished men of the eighteenth century, even those who afterwards turned free-thinkers, and railed at the Jesuits as a society, had received their first education from them; and some of them have had the frankness to acknowledge the merits of their instructors. The sceptical Lalande paid them an honest tribute of esteem and of regret at their fall: even Voltaire spoke in their defence. Gresset addressed to them a most pathetic valedictory poem, 'Les Adieux.' The bishop De Bausset, in his 'Vie de Fénélon,' has inserted a most eloquent account of the Institution of the Jesuits, of their mode of instruction, and of the influence which they had, especially in the towns of France, in preserving social and domestic peace and harmony. For the Jesuits did not exclusively apply themselves to the instruction of youth; grown-up people voluntarily sought their advice concerning their own affairs and pursuits in life, which they always freely bestowed; they encouraged the timid and weak, they directed the disheartened and the forsaken towards new paths for which they saw that they were qualified; and whenever they perceived abilities, good will, and honesty, they were sure to lend a helping hand. The doors of the cells of the older professed fathers were often tapped at by trembling hands, and admittance was never refused to the unfortunate. In private life at least, whatever may have been the case in courtly politics, their advice was generally most disinterested. It has been said that they excelled in the art of taming man, which they effected, not by violence, not by force, but by persuasion, by kindness, and by appealing to the feelings of their pupils. If ever mankind could be happy in a state of mental subordination and tutelage under kind and considerate guardians, the Jesuits were the men to produce this result; but they ultimately failed. The human mind is in its nature aspiring, and cannot be permanently controlled: it cannot be fashioned to one universal measure; and sooner or later it will elude the grasp of any system, whether military or political, ecclesiastical or philosophical, and will seek, at any cost, to gratify its instinctive desire for freedom.

Among the members of their own society the Jesuits have had distinguished men in almost every branch of learning. In the mathematical sciences we may mention, among others, Jacquier, Le Sueur, Boscovich, and Le Maire; in classical literature, Petau, Sirmond, Jouvency, Lagomarsino, Tursellini, &c.; in general literature, Possevin, Bettinelli, Tiraboschi; in ecclesiastical learning and sacred oratory, Bellarmino, Pallavicino, Segneri, Bourdaloue; in

Oriental philology, Kircher, Ignazio Rossi, Amiot, Gaubil, &c. The 'Fasti Societatis Jesu,' the 'Acta Sanctorum S. J.,' the numerous letters and memoirs of the various missions, may be consulted in order to judge of the value of Jesuit learning and labour.

JESUITS' BARK. [CINCHONA.]

JESSULMER. [HINDUSTAN, p. 221.]

JESUS. [CHRIST.]

JESUS, son of Sirach, was a learned Jew of Jerusalem, who employed himself in collecting sayings of wise men, from which, with additions of his own, he formed the book of ECCLESIASTICUS. (*Ecclesiasticus*, ch. l., ver. 27.) We know little of him but what we can gather from that book. According to Bretschneider, he composed it about 180 B.C.; a date which is rendered probable by the fact that, in enumerating the illustrious men of the Hebrew nation, the last he mentions is the high-priest Simon, the son of Onias, of whom he speaks in terms which make it probable that he had seen him; while he does not mention the Maccabees.

Another Jesus, a grandson of the former, and whose father's name is also supposed to have been Sirach, translated the book of Ecclesiasticus into Greek, probably about 130 B.C.; for he states in his prologue to the book that he went into Egypt in the reign of Euergetes (Ptolemy VII., Euergetes II.), and there executed the translation.

This is the general opinion; but Jahn thinks it probable that Jesus composed the book of Ecclesiasticus about B.C. 292—280; that the Simon, son of Onias, whom he praises, was the first of that name, not the second; and that his grandson executed the translation under Ptolemy Euergetes I., who reigned B.C. 247—222. He founds this opinion chiefly on the character of Simon I. agreeing with the eulogy of the writer better than that of Simon II.

(Bretschneider, *Liber Jesu Siracidæ*; Horne's *Introduction*, vol. iv.; Jahn, *Introd. in Lib. Sac. Vet. Fœd.*)

JESUS COLLEGE, CAMBRIDGE, was founded in 1496, by John Alcock, bishop of Ely, who had obtained from King Henry VII. a grant of the nunnery of St. Radegund, then lately suppressed; all the lands which had been bestowed upon that monastery were given as an endowment, and the buildings were converted into a college. It has sixteen foundation fellowships, open to natives of England and Wales, without any restriction or appropriation whatsoever; five of the original foundation, four founded by Dr. Fuller, master of the College, and the rest by various benefactors. Six of the fellows are required to be in priests' orders. On every vacancy of a fellowship the master and fellows nominate two candidates, of whom the bishop of Ely elects one. There is one fellowship, founded by James Stanley, bishop of Ely, to which the bishop has an exclusive right both to nominate and appoint. The mastership of this College is in the absolute appointment of the bishop of Ely. Various scholarships, exhibitions, and smaller foundations, of different annual values, from 70*l.* to 3*l.* 6*s.* 8*d.*, have been bestowed on this College from time to time by different benefactors. It has also some annual prizes of value. The total number of members upon the boards of this College, on March 12, 1838, amounted to 179. Its patronage consists in the rectories of Graveley and Harlton in Cambridgeshire, of Stanley Regius in Gloucestershire, Tewing in Herts, and Cavendish and Whatfield in Suffolk; and in the vicarages of All Saints and St. Clement's in Cambridge, those of Comberton, Fordham, Guilden Morden, Hinxton, Swavesey, and Whittlesford, in Cambridgeshire; of Elmstead in Essex, and of Hundon in Suffolk. (Lysons's *Cambridgeshire*, pp. 118, 119; *Camb. Univ. Calendar* for 1838.)

JESUS COLLEGE, OXFORD, owes its foundation to the zeal of Hugh ap Rice, or Price, a native of Brecknock, who, when far advanced in life, meditated the establishment of a college which should extend the benefits of learning to the natives of Wales, an advantage which, previous to his time, had not been provided for at Oxford. With this intention he petitioned Queen Elizabeth that she would be pleased to found a college on which he might bestow a certain property. Her Majesty accordingly granted a charter of foundation, dated June 27, 1571, prescribing that the college should be erected by the name of 'Jesus College, within the City and University of Oxford, of Queen Elizabeth's foundation;' the Society to consist of a principal, eight fellows, and eight scholars; and for their maintenance Dr. Price (for he had now become a Doctor of Civil Law) was permitted to settle estates to the yearly value of 160*l.* To this the queen added a quantity of timber from her forests of Shotover and Stow. The founder's estates, which he conveyed June 30, lay in Brecknockshire; and he bestowed upwards of 1500*l.* upon the building, leaving besides some money, which was suffered to accumulate, and which, in the beginning of the seventeenth century, amounted to 700*l.* Hugh Price, who was a prebendary of Rochester and treasurer of St. David's, died in August, 1574. In 1589 the Society procured another charter of the queen, empowering them to hold possessions to the value of 200*l.* per annum, and to appoint commissioners for the drawing up of statutes.

King Charles I. in 1636 founded a fellowship to be held by a native of Guernsey or Jersey; Bishop Westphaling and Sir John Walter founded one for a native of England; Bishop Rowlands, Dr. Francis Mansell, Dr. Thomas Gwynne, and others, added fellowships and scholarships for natives of different districts of Wales, or for schools in the principality; and Sir Leoline Jenkins, who was almost a second founder, bequeathed to the College divers lands and tenements for augmenting the then sixteen fellowships and sixteen scholarships, and for founding two additional fellowships and scholarships. One fellowship was afterwards added, by a decree in chancery, out of the residue of Sir Leoline's personal estate. So that the Society at present consists of a principal, nineteen fellows, and eighteen scholars.

Several exhibitions have likewise been founded by different benefactors, of which twenty-four are for natives of North Wales, by the Rev. Edmund Meyrick, M.A., treasurer of St. David's; three for Caermarthenshire, by Bloom; two for Brecknockshire, or Radnorshire, by Powell; one for a native of Ruthin, or diocese of St. Asaph, by Bishop Parry; one for Caernarvonshire, by subscription, to be called Mr. Assheton Smith's; two by Le Hunt; four by the Grocers' Company; two by the Salters' Company; and some connected with the Cowbridge School foundation by Sir Leoline Jenkins.

The patronage of this College consists in the rectories of Longworth and Remenham in Berks; of Ashton Clinton in Buckinghamshire; of Bagendon, or Badgington, in Gloucestershire; Scarthe in Lincolnshire; Brandeston and Furthoo in Northamptonshire; Rotherfield Pipard and Wiginton in Oxfordshire; Nutfield in Surrey; Tudington in Worcestershire; Llandyssil in Cardiganshire; Clynnog Vawr and Llan Wuda in Caernarvonshire; and Llandon in Glamorganshire; with the vicarages of Shipston-cum-Tidmington in Worcestershire, and Holywell in Flintshire; the impropriation of Badgworth, and the chapelry of Charlton Kings, in Gloucestershire; and the impropriations of Holyhead, Bodedern, and Llandrygarn with Bodwrog, in Anglesey.

The present number of members upon the books of this College is 149.

(Gutch's *Colleges and Halls*; Chalmers's *Hist. of the Univ.*; *Oxford Calendar*, 1838.)

JET, a variety of coal, which occurs sometimes in elongated reniform masses, and sometimes in the form of branches, with a woody structure; fracture conchoidal; soft and brittle; sp. gr. but little greater than that of water; lustre brilliant and resinous; colour velvet black; opaque. It is found in Saxony, and also in the Prussian ambermines, in detached fragments. The finer sorts are used for the manufacture of ornaments and trinkets, and the coarser kinds as fuel; it burns with a greenish flame and a strong bituminous smell, and leaves a yellowish ash.

JETHOU. [GUERNSEY.]

JETSAM. [FLOTSAM.]

JEWELL, JOHN (born 1522, died 1571), one of the fathers of the English Protestant church. He was born in Devonshire, and educated in grammar-schools in that county, till at the age of thirteen he was sent to Oxford, where he was entered at Merton College, under the tuition of John Parkhurst, who was afterwards the Protestant bishop of Norwich. When eighteen, he was admitted B.A., and at that early age he became a college tutor. Henry VIII. was still upon the throne, and it was hazardous for any one to make himself conspicuous either as an opposer of the principles of the Reformation or as an advocate of them. Jewell therefore kept himself quiet, contenting himself with inculcating Reformation principles privately in his lectures to his pupils; but when King Henry was dead, and the ecclesiastical policy of the country became more decidedly

Protestant under his successor, Jewell declared himself openly a zealous Protestant; and when Peter Martyr, one of the foreign reformers, visited Oxford, and there held a public disputation (as was the manner of those times) with certain learned Catholic divines, Jewell acted as his notary. From this time he became a zealous promoter of the Reformation, both at the university and as a preacher and catechiser in the country about Abingdon, where he had a living.

Times however changed; King Edward died, and a new policy was adopted. It was sought to undo what had been done. Jewell, it seems, for a short time somewhat temporized; but he very soon recovered himself, and sought shelter in a foreign land from the severity of the storm which fell upon those who, in the preceding reign, had been zealous for the Reformation. He joined the English exiles at Frankfort, and afterwards at Strasburg, where he again met with Peter Martyr, whom he assisted in the composition of some of his works. The reign however of Mary was short, and with the accession of Elizabeth came brighter prospects to the friends of reform. Jewell returned home, and was almost immediately made bishop of Salisbury. His zeal was not relaxed. He continued both by his preaching and his writing to promote the doctrines of the Reformation, and to endeavour to extinguish whatever attachment there might still remain, especially in any part of his own diocese, to the older system. He died, in the course of one of his preaching tours, at the little village of Monkton Farleigh, in an obscure corner of his diocese, in the fiftieth year of his age. Camden, whose testimony is worth more than that of any party writer on either side, bears to him this testimony, that he was a man of singular ingenuity, of vast erudition in theology, and of eminent piety.

The writings of Jewell are chiefly controversial, the most remarkable of them being his 'Apology for the Church of England,' and his various Defenses of that Apology. These are together considered one of the ablest defences of the Protestant Church of England that appeared, and were translated into many languages for the purpose of circulation abroad. His writings were collected in a large folio volume in 1609. Copies of this volume were placed in many of the English churches for the common use of the parishioners, and may sometimes even now be found fastened by a chain to a reading-desk. This honour it has shared with Fox's 'Acts and Monuments of the Church,' and some of the theological writings of Erasmus.

The writings of Jewell are still greatly valued, and are much used in two departments of ecclesiastical controversy, the question between the Church of England and the Church of Rome, and the question respecting the doctrinal sentiments of the fathers of the Protestant Church of England. Lists of his writings may be seen in the 'Athenæ Oxonienses' of Anthony Wood, where is an outline of his life, the particulars of which have been written more in detail by many persons.

JEWELLING OF WATCHES is the art of setting diamonds, rubies, sapphires, chrysolites, or other hard stones, in the frame-plates and other parts of watches, in such a manner that the pivots of the watch may act in holes made in these stones. There are two kinds of jewelled holes necessary in watches, one of which is merely a perforation through the stone; the other consists of a perforated piece, and a piece called an end-piece. The latter mode of jewelling is adopted where it is necessary that the end of the pivot, and not the shoulder, should sustain the weight of the wheel whenever by a change of place it is brought into a vertical position, which is important in those cases where the pivot has a rapid motion and considerable weight to sustain, as the pivots at each end of the axis of the balance.

The province of the watch-jeweller is to select the stones, and, except in the case of diamonds, to grind, polish, turn, drill, and set them into the frames or other parts of the watch in such a manner that the holes in the stones may correspond exactly in position with holes previously made by the watch-finisher or escapement-maker. Jewelling is an operation which when well performed adds materially to the durability, and not a little to the elegance of the machine. A hole without an end-piece is thus made: the hole in any piece to be jewelled having been made in its proper place by the finisher, the piece is so fixed in a lathe by the jeweller that the hole shall be perfectly concentric to the centre of motion; this hole is then enlarged by turning, and afterwards so formed that a small circle of brass which contains the stone, and which is called the setting, may have a cavity to rest in, without the possibility of its going through the plate, or piece in which the hole has been made. After the setting has been fitted to the cavity, and adjusted so as to be flush with the plate, two screws are inserted in the plate so near to the cavity which contains the setting that the edges of the screw-heads project a small distance over the edge of the setting, and thereby secure it in its place. When a hole with an end-piece is required, the same process is adopted, but two stones are required for each hole instead of one, and the first or perforated stone with its setting is sunk into the cavity already described a sufficient distance below the surface of the plate to allow of the reception of a second setting, containing a stone which resembles in form a small slice cut from a sphere about the size of a shot, its form being plano-convex. The edge of this second setting is left flush with the plate or piece in which the cavity is made, and two screws being inserted, as in the former case, the two settings are secured at once. It must be remembered that the stone last inserted has no hole through it. The mode of forming the stones, &c. will be presently described, but it will be as well to observe here, that in the holes already described the stones are secured in their brass settings in a manner somewhat similar to that in which opticians set many of their glasses in telescopes, namely, by turning a place to receive the stone, and leaving a fine edge of brass, which is subsequently rubbed over the edge of the stone with a burnisher. Jewelling has sometimes to be performed in situations where there would not be room to insert the fastening screws without weakening the part, as in the foot of a watch potence. In this case the first stone is inserted with its setting into a cavity as already described, with the surface of the setting flush with the surface of the part into which it is placed, but the surface of the stone is so much lower than that of the setting as to allow of a dovetailed notch or slit being cut through it, and along the surface of that part which receives the setting, so that a small brass dovetail pushed tight into this groove or slit secures the setting in its place; and at that part of the dovetail which immediately covers the hole in the stone is inserted another small piece of stone, which forms an end-piece to the hole. When a diamond end-piece is used, it is usually set in steel, into which it is brazed, the diamond being a stone which will allow of heat sufficient for that purpose. After brazing, the steel is turned into shape, polished, and blued.

The apparatus necessary for the jeweller to carry on his business are a small lathe, the action of which in its collar should be as light as possible; small gravers for turning brass and steel; a quantity of rough diamond in fragments, technically termed *bort;* small mills or circular disks of metal (usually copper) for grinding the stones into shape; diamond-powder of various degrees of fineness for polishing; and turning tools made by cementing small pieces of bort into a notch made in the end of small brass wires and fixed in proper handles. In the preparation of a stone for a jewel-hole, it is necessary first to charge a copper disk about the size of a penny piece, and out of which it is frequently made with bort, which is done by strewing a quantity of it upon the copper, and by strokes and pressure from a hammer embedding it into the surface; the mill thus prepared is fixed unto the mandrel of the lathe, which is put in motion by a band from a rather large foot-wheel, the mill making from 6000 or 7000 to more than 20,000 revolutions in a minute, the latter velocity being given only in the act of polishing. The stone to be formed is then taken on the end of one of the fingers of the right hand and applied to the surface of the bort-mill, which is kept constantly wet with water applied by the fingers of the left hand, and in a few seconds a flat surface is produced on a stone of the most irregular form; the flat surface is then placed next the finger, and a similar surface is produced parallel to the former, until the stone is of such a thickness as is required; it is then placed, by means of cement, on a small chuck in the lathe, and with one of the before-mentioned bort tools turned into the proper shape for setting; the hole is also drilled either with a steel drill and diamond-powder and oil, or with a drill made of bort or small fragments of diamond. In drilling the hole it is necessary to drill the stone about half way through, after which the stone is reversed, and the drilling commenced on the opposite side, to prevent the fracture which would be likely to take place if the drill-

ing was continued through to the opposite surface. The piece of stone, or hole, as it is called, is also turned with a hollow or countersink to receive the oil necessary for the lubrication of the pivot. A piece of brass, one end of which is shaped to fit the hollow, is charged with fine diamond-powder, the finger being applied to the other end, and by pressing it against the stone, and at the same time by a motion of the finger giving every possible change of position to the brass which is compatible with keeping it in the hollow of the stone, from which it should not be suffered to slip, the stone is beautifully polished. The stone is afterwards detached from the lathe, and its flat or parallel surfaces polished by rubbing it with all the rapidity of which the hand is capable on a piece of plate-glass, previously charged with a small quantity of diamond-powder and oil. When an end-piece is required the same process is gone through, except that the drilling is omitted, and the spherical side of the stone is polished by using a piece of brass with a hollow end to suit the convexity of the stone. The jeweller also makes use of a small spirit-lamp to heat the cement when he applies it for the purpose of securing the stones upon the chucks in the lathe, and after one side of a stone has been made true by turning, and the hole drilled partly through the stone as before stated, it is reversed, and fixed perfectly true on the chuck by keeping the cement so warm that the stone may be moved by the pressure of a piece of wood or metal, which the workman makes use of for that purpose, by applying it to the edge or surface of the stone, as required, while the lathe is in motion. Another and very ingenious mode of changing the surface of the stone for the purpose of completing the operation of drilling without detaching it from the cement is the following:—A hollow chuck is made to fit upon the lathe, into the exterior edge, of which a groove is turned to receive a lid or cover, which is turned true, and so formed upon the edge that it will snap tight into the before-named groove with either of its sides outwards, a small piece being taken out of its edge to allow of the insertion of any small tool to remove the cover in the same way as the cover is removed from a watch-barrel. A small hole is made in the centre of this cover, over which the stone is cemented, and when the drilling on one side is completed, the cover, and with it the stone, is removed, and by snapping in the cover the contrary side outwards the other surface of the stone is presented to the operator, and the act of drilling is repeated; for the cover and groove being turned perfectly true, the centre of motion of the stone is not affected by the reversing of the cover.

The end-pieces, when real diamonds are used, are what are called rose diamonds, and are procured from Holland, where they are cut.

JEW'S-HARP, a musical instrument of the simplest and rudest kind, consisting of an iron frame, resembling in form the handle part of an old-fashioned corkscrew, in the centre of the upper and wide part of which is riveted at one end an elastic steel tongue, the extremity of which, at the free end, is bent outwards to a right angle, so as to allow the finger easily to strike it when the instrument is placed to the mouth and firmly supported by the pressure of the parallel extremities of the frame against the teeth.

Professor C. Wheatstone has shown that the sounds of the Jew's-harp mainly depend on the reciprocation of columns of air in the mouth of the performer, and that these sounds are perfectly identical with the multiples of the original vibrations of the instrument. Hence its scale must necessarily be very incomplete; but by employing two or more instruments, the deficiencies are supplied. A few years ago, an ingenious foreigner, M. Eulenstein, exhibited in London, at the Royal Institution, his very extraordinary talent on the Jew's-harp. He used sixteen instruments of different sizes, and was thus enabled to modulate into every key, and to produce effects not only original, but musical and agreeable.

JEWS (Ἰουδαῖοι and JUDÆI in Greek and in Latin), in its widest acceptation, is used as synonymous with Hebrews, or Israelites, but in a more restricted sense it means the inhabitants of the kingdom of Judæa as it existed in the time of Jesus Christ, and whose descendants are now scattered over all the world. The history of this people previous to the time of Christ is contained in the Old Testament and in Josephus. Their great ancestor Abraham, called 'the Hebrew' (*Genesis*, xiv. 13), by birth a Chaldæan, emigrated, about 1921 years B.C., with his wife Sarai, his nephew Lot, and his numerous servants and flocks, into the land of Canaan, the modern Palestine, where he settled. [ABRAHAM.] At an advanced age his wife bore him a son, Isaac, from whom the Hebrews are descended. Abraham's elder son Ishmael, whose mother was an Egyptian and a slave, settled in the wilderness of Arabia. Isaac married Rebecca, by whom he had two sons, Esau and Jacob, the former of whom was a hunter, and gave up his birthright to his younger brother Jacob. Jacob, surnamed Israel, or 'the strong' (*Genesis*, xxxii. 28), had twelve sons, namely Reuben, Simeon, Levi, Judah, Dan, Naphtali, Gad, Asher, Issachar, Zabulon, Joseph, and Benjamin. From these were descended the twelve tribes of Israel, or of the Hebrew nation. One of Jacob's sons, Joseph, came by a singular course of vicissitudes to be first minister to one of the Pharaoh kings of Egypt, and he settled his brethren in a fertile district of that country, where his and their descendants throve and multiplied so as to form in the course of about two centuries after Joseph's time a very numerous colony subject to the Egyptians, by whom they were disliked as aliens, and treated with great harshness. Being driven to despair, they found a leader in one of their countrymen, Moses, who, acting under the special direction of God, led them out of the land of Egypt, to return to that of their ancestors, Canaan, the possession of which God had promised to the posterity of Abraham. The number of the Israelites at their departure from Egypt is stated in *Exodus* (xii. 37) at six hundred thousand men, besides women and children, with their flocks and herds of cattle. Being pursued by the Egyptians, they crossed on dry land the northern extremity of the western of the two great gulfs in which the Red Sea terminates, now called the gulf of Suez, and entered the peninsula of Sinai, in Arabia. The waters of the sea, which, at the command of the Lord, had divided and made a passage for the children of Israel on dry land, returned at the same command, and overwhelmed their pursuers.

The departure of the Israelites from Egypt took place, according to most chronologists, in 1491 B.C. [EXODUS.] On Mount Sinai Moses received from God the law of the Ten Commandments, and from that time the Israelites were taught to consider themselves as being under the immediate government of the deity, who, from time to time, made known his will to them through their leader Moses. The books of Moses called *Exodus* and *Leviticus* contain the civil laws and social regulations, as well as the rites and religious ceremonies. Other laws which were successively promulgated are found in the following books of *Numbers* and *Deuteronomy*, so as to form a complete body of institutions for the Hebrew community. Of these laws some were temporary directions suited only to the nomadic state in which the Israelites spent many years in the wilderness; others are enactments intended for an agricultural people with settled habitations, and for the time when they should become possessed of the promised land of Canaan. Sanitary regulations concerning diet, cleanliness, and decency form an important part of the code, and are admirably adapted to the people, country, and climate for which they were intended. The political system was founded upon equality, without any distinction of castes; the whole nation was to be one great body of husbandmen cultivating their own property. The land could not be alienated in perpetuity; every fiftieth year a jubilee was to take place, when all estates which had been alienated were to revert to their original owners, and all burthens, debts, and other engagements were to cease.

One tribe, the descendants of Levi, was set apart for religious service: they had no tract of country assigned to them, but were to dwell by themselves in separate towns or villages, scattered through the territory of the other tribes. Out of this class the officiating priesthood was chosen, as well as the scribes and keepers of records, the judges, and perhaps also the physicians. They were in fact the learned class of the nation; they read the law to the people, and they attended by rotation on the officiating priests in the Tabernacle. One-tenth of the whole produce of the land possessed by the other tribes was assigned to the Levites for their maintenance. Each tribe had its own chieftain or prince, and the heads or elders of each family constituted the provincial assembly. On occasions of great emergency, national assemblies were held, probably consisting of delegates from each tribe, and their resolutions were ratified by the general voice of the people expressed by acclamation. This took place repeatedly during their encampment in the

desert. All who could bear arms were bound to fight in the common defence. The penal laws were severe, but considerate; punishments were fixed for every offence; nothing was left to caprice. Parental authority was enforced, but the law prevented its abuse; the father had no power of death over his children, and he could not disinherit them; the first-born received two portions, and the rest shared equally. No Hebrew could be sold or sell himself as a bondsman for life; he might hire himself as a servant for a period, but at the end of six years he became free again, unless he chose to renew his term for another six years. Foreign slaves however, whether captives or purchased, were held in perpetual bondage, both they and their children; but the law provided for their protection: they were entitled to rest on the Sabbath, and on the great festivals they partook of the common feasts and rejoicings. The condition of a slave among the Hebrews was better than that of a slave among the Romans and most other nations of antiquity. For further details concerning the constitution of the Hebrews the reader is referred to the 'Pentateuch,' especially to the books of *Leviticus* and *Deuteronomy*.

The office of high-priest was bestowed upon Aaron, the brother of Moses, and his descendants in perpetuity. This dignity was quite distinct from that of civil leader or judge, though in course of time some high-priests occasionally united both offices in their persons. The high-priest was the means of communication between God and the people: he alone could enter the recess of the sanctuary; in important cases there was a final appeal to him; and he was also consulted upon great national affairs. He had the charge of the tabernacle or sanctuary, which was the great bond of union among the tribes of Israel.

After remaining about a year encamped at the foot of Mount Sinai, the Israelites marched towards the land of Canaan, and arrived at Kadesh Barnea on its southern frontier, whence they sent spies to explore the interior. After forty days the spies returned with the information that the country was rich and fertile, but the people fierce, numerous, and strong, and likely to make a stout resistance. The Israelites, long accustomed to bondage, were frightened, and they loudly demanded to be led back to Egypt. Moses saw that the people were as yet unfit for a war of conquest, and on the authority of God he gave the order for retreat, not however for Egypt, but back into the peninsula of Sinai, where they encamped and settled with their flocks and cattle after the fashion of the Beduin Arabs. In this wilderness they remained for thirty eight years, the period assigned for their nomade life, until the first generation which had come out of Egypt had gradually sunk into the grave, and a new race had sprung up in the free air of the desert, trained to the bold and hardy habits of the wandering Arab, but with much of the arts, knowledge, and discipline derived from Egypt. At the expiration of this time, they again moved forward to Kadesh, but Moses perceiving that part of the country to be mountainous and well defended, led them round the eastern shore of the Dead Sea through the land of Edom and Moab. He crossed the Jabbok, defeated the Amorites and the king of Bashan, and encamped in a plain near the left bank of the Jordan above its influx into the Dead Sea, nearly opposite to Jericho. Here, after defeating the Midianites and giving the conquered territory on the west of Jordan to the tribes of Reuben, Gad, and half the tribe of Manasseh, he prepared to lead the Israelites across the river. But before this was effected Moses died, after bestowing his last advice and blessing on the people, assembled for this solemn purpose, and appointing Joshua, a man already tried for his bravery and skill, to be his successor. Joshua crossed the Jordan and took Jericho, and gradually conquered the greater part of Canaan, exterminating or driving away the former inhabitants. The events of the conquest are related in the book of *Joshua*. The country was then divided among the twelve tribes, substituting for those of Levi and Joseph the respective descendants of the two sons of the latter, Manasseh and Ephraim. For the limits of these tribes see PALESTINE.

In this manner the Hebrews became a settled agricultural people, though often at war with their neighbours the Philistines, the Moabites, the Midianites, the Ammonites, and other tribes. Even the whole land of Canaan was not subdued till a much later period, and the Canaanites remained in strength both in the north and the south, and repeatedly harassed the Hebrew colonists, as we observe in the invasion of Sisera (*Judges*, iv.). On these occasions gallant leaders arose among the Hebrews, styled Sophetim in the Scripture, generally translated Judges, who assumed a sort of dictatorial authority, and rescued the nation from danger; each tribe however retained its internal form of government, and often engaged in petty warfare with its neighbours on its own account. This period of the history of the Jews, which is called the period of the Judges, and which lasted about four centuries, may be considered as the heroic age of the nation, which still retained a primitive simplicity of manner, beautifully portrayed in the tale of Ruth. Samuel was the last of the Judges: he drove away the Philistines who had occupied a great part of the country, but the people growing tired of these frequent invasions, which they had not discipline or union enough among themselves to guard against, wished for a more settled form of government, and demanded of Samuel a king to rule over them. Samuel remonstrated on the dangers of despotism, but the people were determined in favour of the change, and Samuel appointed a youth named Saul, of the tribe of Benjamin, and anointing him, solemnly gave up the authority into his hands. The reign of Saul was long and agitated; he quarrelled with Samuel, and committed various acts of tyranny. Samuel then foretold the downfal of the house of Saul, and he secretly anointed as his successor a youth of the tribe of Judah, called David, who was distinguished for his bravery as well as for the comeliness of his person. Saul having discovered that his successor was already appointed, persecuted David, whose adventures constitute a narrative of romantic interest in the book of *Samuel*. Saul fell in battle against the Philistines, and David succeeded him, about 1056 B.C. The reign of David, which lasted forty years, forms a splendid epoch in Jewish history. He was victorious over all his neighbours. He reduced not only the whole of Canaan, but took possession of the country of Edom as far as the Red Sea, of Moab, of part of Syria, and formed alliances with the kings of Hamath and of Tyre. His power extended from the borders of Damascus to the Elanitic or eastern branch of the Red Sea, and from the coast of the Philistines to near the Euphrates.

David took Jerusalem, which was a town and fort of the Jebusites, a Canaanitish tribe till then unconquered, and made it the capital of the kingdom. He died at an old age, leaving to his son and successor Solomon a flourishing and secure kingdom, a full treasury, and a well disciplined militia. The reign of Solomon was long and peaceful. He raised the famous temple on Mount Moriah, on the east side of Jerusalem, and employed Tyrian and other foreign artificers for the purpose. Solomon was a very wealthy prince: he encouraged commerce, and had ships on the Red Sea manned by Tyrians, which traded with Ophir. His close alliance with the Phœnicians was of great advantage to him; he supplied them with corn, and received timber from Lebanon and other goods in exchange. The Phœnician caravans to Arabia and to Persia passed through his dominions. His own subjects carried on a trade with Egypt, with which country Solomon was on friendly terms, and he married a daughter of one of the Pharaohs. He is said to have built Tadmor or Palmyra, and Baalbek; but his great expenditure, and the taxes by which he supplied his wants, made the people dissatisfied, whilst his own example encouraged them in their licentiousness and effeminacy. He died after forty years' reign, and his son Rehoboam was only able to retain possession of the southern part of the country, comprising the territory of Judah and Benjamin, which then assumed the name of the kingdom of Judah, while the other ten tribes elected Jeroboam as their king, and retained the name of the kingdom of Israel, which had first Sichem, and afterwards Samaria, for its capital. This division took place about 975 B.C. The kingdom of Israel lasted 250 years, through a succession of stormy and blood-stained reigns, and was in the end overthrown by the Assyrians, who carried the inhabitants into captivity, from which they never returned, nor has the existence of their progeny ever been ascertained. The kingdom of Judah lasted above a century and a half longer under the dynasty of the house of David, until Nebuchadnezzar, king of Babylon, after repeated invasions, destroyed Jerusalem, 588 B.C., and carried its inhabitants into captivity. Thus the Jewish monarchy terminated after a period of about five centuries from its first institution, the stirring events of which period are related in the books of *Kings* and *Chronicles*. During this time flourished the prophets Isaiah, Jeremiah, Amos, Hosea, Joel, Micah, Nahum, Ze-

phaniah, Jeremiah, and Habakkuk. Daniel and Ezekiel belong to the period of the Captivity.

The captivity of Judah lasted seventy years, after which Cyrus, having conquered Babylon, allowed the Jews to return to their own country. They assembled for that purpose to the number of 42,360, under Zerubbabel, a descendant of their kings, and on arriving in Judæa were joined by those of the common people and cultivators of the soil who had remained in their native country. They began rebuilding Jerusalem and the Temple, and their neighbours the Samaritans, who inhabited part of the territory of the former kingdom of Israel, offered to join them in the furtherance of the great national work; an offer however which was contemptuously rejected by the Jews, who looked upon the Samaritans as alien colonists, although the Samaritans themselves asserted their descent from the tribes of Ephraim and Manasseh. When the Assyrians led the ten tribes into captivity, they probably took away only the higher class of people, as the Babylonians did with those of Judæa, and did not depopulate the whole country; besides which, during the course of more than two centuries, and particularly after the subversion of the Assyrian empire, many exiles or descendants of exiles may have found their way back to their native land. The fact that the Samaritans have preserved the 'Pentateuch' in the original characters, while the Jews on their return from Babylon adopted the Chaldæan form of letters, is strongly in favour of their Israelitish descent, though they may have been mixed by alliance with Assyrian and other colonists. The Jews however always showed a deadly animosity against the Samaritans, whom they insisted on considering as aliens and idolaters, although they in reality acknowledged the law of Moses.

The character of the Jews themselves had undergone a considerable change during their Babylonish captivity. They had become more exclusively attached to their country and their laws, and we hear no more of their proneness to idolatry after that epoch, as in former times. They strictly avoided intermarriage with foreigners, and assumed in every respect that unsocial spirit towards all except their own community for which they have been so often reproached. Adversity had soured their minds, while the expectations of a Messiah who was announced by their prophets roused the national pride. The doctrine of the immortality of the soul, which is not mentioned in the Mosaic law, was also introduced, especially among the great sect of the Chasadim, or Pharisees.

Under the mild rule of the Persian kings the Jews enjoyed many of the advantages of independence united with security. They were allowed the management of their internal affairs, and the high-priest was their chief magistrate. In this manner they lived quietly and unnoticed, but yet thriving, for about two centuries, till the year 333 B.C., when Alexander, after gaining the battle of Issus, appeared in Syria. Jerusalem made its submission, and was spared by the conqueror. After Alexander's death, Judæa fell under the dominion of the Ptolemies, who showed favour to the Jews, and planted colonies of them in their capital Alexandria, and at Cyrene. The high-priests continued to have the direction of the internal administration of the country. From the Ptolemies Judæa passed under the rule of the kings of Syria, under the reign of Antiochus the Great, 198 B.C. Antiochus visited Jerusalem, and confirmed the privileges which the Jews had enjoyed under the Ptolemies; but under the reign of his second son Antiochus Epiphanes, owing to the intrigues of several aspirants to the high-priesthood, an insurrection broke out in Jerusalem, which was put down by Antiochus with great slaughter of the inhabitants. Antiochus now attempted what no one had attempted before him, to force the Jews to renounce their God and worship Jupiter of Olympus, whose statue was erected on the altar of the Temple. The Jews generally refused. Great cruelties were committed by the officers of Antiochus against the recusants in every part of Judæa, until a spirited resistance begun by Mattathias, and continued under his son Judas, styled Maccabee, had the effect of delivering the country from the hateful oppression of the Syrians. [MACCABEES.] The Maccabees were a family of heroes. After the death of Judas and two of his brothers who fell in battle, Jonathan, another brother, continued the struggle, and having formed an alliance with Rome, was left at last in quiet possession of Judæa. A revolution in the kingdom of Syria added to his strength and importance. Alexander Balas, who claimed the crown of Syria, offered Jonathan the high-priesthood and exemption from all tribute and taxes, besides other advantages, if he would support him against his rival Demetrius. Jonathan assented, and Balas having seated himself on the throne, 150 B.C., presented Jonathan with a purple robe, and appointed him meridarch of Judæa, a title which, under his successors, was changed into that of king. With Jonathan begins the dynasty of the Asmonæans, or 'Illustrious,' which ruled Judæa for about a century, and under which the country resumed a degree of independence and splendour, which it had not experienced since the reigns of David and of Solomon. [ASMONÆANS.]

The last of the Asmonæan dynasty were put to death by Herod son of Antipater the Idumæan, who, with the support of the Romans, became king of Judæa, 38 B.C. [HEROD THE GREAT.] He died in the same year that Christ was born, although in the common chronology the birth of Christ is placed four years later. With Herod the independence of Judæa may be said to have expired. His son Archelaus was appointed ethnarch of Judæa Proper, Idumæa, and Samaria; his brother Herod Antipas had Galilee and Peræa; to Herod Philip were given the provinces of Trachonitis, Batanæa, and Gaulonitis, east of the Jordan, and another Philip had Ituræa. Thus the dominions of Herod were dismembered between four of his sons, who are accordingly styled Tetrarchs in the New Testament. Archelaus was summoned to Rome after a reign of nine years, to answer certain charges brought against him by his subjects, and was banished by Augustus to Vienne in Gaul. Judæa thus became a Roman province, or rather a district dependent on the great province or prefecture of Syria, though administered by a special governor, a man usually of the Equestrian order. This is the state to which Judæa was reduced in the time of our Saviour. The Jews however continued to enjoy the exercise of their religious and municipal liberties.

Under the reign of Claudius, Herod Agrippa, grandson of Herod the Great, who had been already appointed by Caligula ethnarch of Galilee, was appointed king of Judæa and all the former dominions of his grandfather, but he died three years after, at Cæsarea in Palestine, A.D. 44: this is the Herod mentioned in chapter xii. of the *Acts*. His son, called likewise Herod Agrippa, was then a minor, and Judæa relapsed into a Roman province. In A.D. 53 Claudius gave to Agrippa the provinces east of Jordan, which had belonged to Philip the Tetrarch, and Nero added to them part of Galilee. But Judæa and Samaria continued to be administered by Roman procurators. Herod however was entrusted by the emperor with the superintendence of the Temple and the right of appointing and deposing the high-priest at Jerusalem, and he occasionally resided in that city, while the Roman governor generally resided at Cæsarea. This second Herod Agrippa is the one mentioned in *Acts*, xxv., xxvi., there styled King Agrippa, whom St. Paul addressed in so impressive a manner in his defence. Agrippa was present at the final catastrophe of Jerusalem.

A succession of more than usually rapacious Roman governors, Felix, Albinus, and Florus, had driven the Jews to the verge of despair. A tumult, which broke out at Cæsarea between the Greeks and the Jews, followed by fresh exactions and cruelties of Florus, who seemed to wish to drive the people into insurrection, led the way to an open revolt against the Romans. Agrippa, who, with his sister Berenice, happened to be at Jerusalem, remonstrated with the people on the rashness of the attempt, but in vain, and he withdrew to his own dominions. A party called the Zealots, or fanatics, now obtained the ascendency over the minds of the people, and the feeble Roman garrison was overpowered and massacred. At the same time the Greeks of Cæsarea massacred all the Jews in that city, and the Roman governor Florus took no notice of the transaction.

Other cities of Palestine and Syria followed the example of Cæsarea by a wholesale butchery of the Jews. The Jews retaliated in those towns of Palestine where they were the majority by murdering the Syrians and Greeks. Cestius Gallus, the prefect of Syria, who had winked at the exactions of Florus, now advanced against Jerusalem with one legion and many auxiliaries, but he was obliged to retire, and was completely defeated by the insurgents in his retreat, with the loss of nearly 6000 men. The revolt now became universal throughout Judæa and Galilee. Nero, who received the news in Achaia, sent for Vespasian, an officer of tried abilities, and gave him the

command of Syria, A.D. 66-7. Vespasian assembled his forces at Ptolemais, where he was joined by Agrippa and by his own son Titus. His army, including auxiliaries, amounted to 60,000 men. For one year he employed himself in scouring the country and reducing the strongholds of the Jews. In the following year, A.D. 68, he was advancing to form the siege of Jerusalem, when he received the news of Nero's death, followed by the rapid succession of Galba, Otho, and Vitellius. Vespasian kept his troops ready for a more important enterprise than the taking of Jerusalem. That city had in consequence a respite of nearly two years, during which however the inhabitants destroyed each other through intestine factions. At last Vespasian was proclaimed emperor, and having defeated Vitellius and entered Rome, he sent his son Titus to complete the subjugation of Palestine. The regular siege began in the spring of A.D. 70, and it lasted till the following September, when Jerusalem was finally taken and totally destroyed, with its temple: the inhabitants were killed or sold as slaves. The fearful events of that siege are narrated by Josephus. The Arch of Titus at Rome is a standing record of the conquest. The landed property of the country was put up to sale. Still the Jewish population was by no means extirpated from the country, and we find them rising in vast numbers in the reign of Hadrian, and again engaging the Roman legions commanded by Severus. They were however overpowered with immense slaughter, and the second desolation of Judæa took place. [BARCOCHEBA; HADRIAN.]

Hadrian issued an edict forbidding circumcision, the reading of the Mosaic law, and the observance of the Sabbath.

The dispersion of the Jews over the world, which is commonly dated from the destruction of Jerusalem, had in reality begun long before. The Ptolemies had transplanted large colonies of them into Egypt, Cyrene, and Cyprus; and Antiochus the Great settled great numbers in the towns of Asia. In the time of Cicero (*Pro Flacco*) there was a wealthy Jewish community in Italy. A passage of Philo, in his letter of Agrippa, enumerates the countries in which the Jews were settled in the time of Caligula: Egypt, Syria, Pamphylia, Cilicia, the greatest part of Asia Minor as far as Bithynia, the shores of the Euxine, Macedonia, Thessaly, Ætolia, Attica, the Peloponnesus, Cyprus, and Crete, besides the countries beyond the Euphrates; for at the end of the Babylonish captivity many Jews voluntarily remained in Mesopotamia, where they continued to form for several centuries a considerable community, alternately under the Parthian and Roman dominion. After the final destruction of Jerusalem, the Mesopotamian Jews acknowledged an hereditary chief, who was called 'the prince of captivity,' while the western Jews, who were scattered all over the Roman empire, had their spiritual head in the patriarch of Tiberias. The civil condition of the Jews throughout the Roman empire has been not unaptly compared with that of the Greeks under the Turks.

Under the Antonines and other succeeding emperors the harsh provisions of the edict of Hadrian were either revoked or allowed to lie dormant, and the Jews were left to follow their old usages and rites, being only prohibited from making proselytes. New synagogues were erected by them, and schools opened in the principal cities of the empire. The Jews by means of their commercial industry acquired considerable wealth, many of them obtained the rank of Roman citizens, and at the same time exemption from military service. During this period of peace, Rabbi Jehuda, one of the patriarchs of Tiberias, composed the 'Mischna,' or code of traditional law, in which he embodied all the authorized interpretations of the Mosaic law, the traditions, the decisions of the learned, and the precedents of the courts or schools. At a later period Rabbi Ascha, a learned Mesopotamian Jew, with the assistance of his disciples, compiled the 'Gemara,' which, with the 'Mischna,' forms the 'Babylonian Talmud,' a work in which the most absurd traditions are mixed up with wise precepts, profound allegories, and pleasing moral apologues.

Constantine made several laws concerning the Jews, one forbidding them to endanger the lives of Christian converts, another prohibiting Christians from embracing Judaism, and a third prohibiting Jews from possessing Christian slaves. Under his successor Constantius an insurrection which broke out in Judæa, and another tumult at Alexandria, in which the Jews were deeply implicated, gave occasion to fresh enactments against them: they were heavily taxed, were forbidden to marry Christian women, and the edict of Hadrian, which prohibited their approaching near to Jerusalem, was formally renewed.

Julian favoured the Jews and proposed to restore their temple. Some extraordinary appearances which are related by Ammianus Marcellinus frightened the workmen who were employed in the restoration, and the death of Julian put an end to the design. Under the following emperors the Jews were protected by the state, though often annoyed by the intemperate zeal of the more violent Christian churchmen. Laws were passed by Theodosius, and confirmed by Arcadius and Honorius, recognising the power of the Jewish patriarch to punish the refractory members of their own community, and the prefects were forbidden from interfering with his judicial authority. In disputes with Christians both parties appeared before the ordinary tribunals. Under Theodosius II. the Jews were forbidden from publicly celebrating certain festivals which occasioned collisions between them and the Christians.

Theodoric and the other Gothic kings of Italy protected the Jews. During the frequent wars and invasions of that period the Jews had the slave-trade of Europe in great measure in their hands; and several councils and Pope Gregory I. interfered to prevent their abusing the power which they had thus acquired over the persons of Christians. That wise and humane pope, in his pastoral letters, bewails and denounces this traffic, which was carried on in Italy, Sicily, Sardinia, and France; he directs the bishops to interfere so as to prevent Jews from retaining Christian slaves when a proper price was offered for them. On another occasion he directs that those Christian slaves who had been long in possession of Jewish landed proprietors should be considered as villains attached to the soil, and should not be transplanted or sold away; he also entreated the Frankish kings to banish the traffic in slaves from their dominions.

Justinian was one of the first who enacted really oppressive and intolerant laws against the Jews. In litigations between Christians and Jews, or between Christians only, the testimony of a Jew or Samaritan was to be rejected; in the litigations of Jews among each other, the Jew's testimony was admitted, but that of a Samaritan or a Manichæan was of no value. By another law, all unbelievers, heathens, Jews, and Samaritans could neither be judges, nor prefects, nor fill any other dignity in the state. Justinian also enacted that in mixed marriages between Jews and Christians the chief authority over the children should rest with the Christian parent. A Jew parent could not disinherit his Christian child. But the Samaritans were treated more harshly: they were entirely deprived of the right of bequeathing or conveying their property to unbelievers. Those of their children who embraced Christianity inherited to the exclusion of the rest. Samaritans could not sue in courts of law. Their synagogues were ordered to be destroyed. By a subsequent edict, and on the humane interposition of Sergius, bishop of Cæsarea, Justinian somewhat mitigated the rigour of these enactments against the Samaritans, but his son Justin again enforced the original statutes against them. The effect of this persecution seems to have been to extinguish gradually that once flourishing community, the members of which probably embraced Christianity for the preservation of their property. In subsequent history the Samaritans no longer appear as a separate people. In the seventeenth century however a small community of them was discovered in the neighbourhood of their holy Mount Gerizim, who still possessed the law in the old Samaritan character, and their descendants exist to this day.

The Jews however were too numerous and strong to be annihilated, like the Samaritans, by imperial edicts: they had even the power of revenge. When Chosroes II. invaded Syria, the Jews of Palestine rose to join the Persians, with whom they entered Jerusalem, then a Christian city, and perpetrated a dreadful slaughter of the Christian inhabitants. They are said to have purchased at a cheap price the captives of their allies the Persians, for the sake of murdering them. The victories of Heraclius however soon put an end to their momentary triumph.

The rise of Mohammedanism brought an unfavourable change to the Eastern Jews; Mohammed endeavoured at first to win them over, but the Jews would not ac-

knowledge a descendant of Hagar the bondwoman as the greatest of prophets, and Mohammed treated them without mercy in Arabia, where they were at that time numerous. But under the Caliphs his successors they were protected on the easy terms of paying tribute, and as they made no resistance, they experienced not only protection but even encouragement from their new masters, whom they followed through their tide of conquest along the coast of Northern Africa. They also contributed materially to the triumph of the Crescent in the Spanish Peninsula.

In Spain, under the Gothic kings, the Jews had experienced the first of those sweeping proscriptions, which they were doomed to suffer in every country of Christian Europe. A series of oppressive laws was passed against them under the significant title of 'Statutes against Jewish Wickedness, and for the General Extirpation of Jewish Errors.' At last King Sisebut commanded them either to forsake their religion or to leave the country. Many fled, others were thrown into prison, and 90,000 are said to have received baptism. The fourth council of Toledo mitigated the rigour of the laws against the Jews by declaring 'that men ought not to be compelled to believe by force, although all who had once embraced the faith must be constrained to adhere to it.' But the eighth council of Toledo, A.D. 653, reinforced the former statutes against the Jews, and following councils enacted more rigorous laws. One hundred lashes on the naked body, chains, mutilation, banishment, and confiscation, were the punishment of those who observed Jewish practices and rites. All converted Jews were put under the strictest surveillance. The acts of the twelfth council of Toledo concerning the Jews are a complete model of ecclesiastical intolerance and refinement in persecution. Under King Egica, while the Saracens were spreading along the shore of Africa opposite to Spain, a general conspiracy of the Jews was reported, and another council passed a decree to disperse the whole race as slaves, confiscate their property, and seize all their children under seventeen years of age, to be brought up as Christians. Many escaped to return with the Saracen invaders, and the munificence of the Mohammedan princes towards them indicates that by their knowledge of the country the Jews had been highly instrumental in advancing the conquest. In Moorish Spain the Jews had really a golden age, which lasted for centuries. There they cultivated science and learning; and the names of Benjamin of Tudela, Isaac of Cordova, Hasdai, the confidant of Abderrahman, and a host of others, attest their proficiency. Rodriguez de Castro (*Bibliotheca Española*) and Vicente Ximeno (*Escritores del Reyno de Valencia*) give notices of the writings of the Spanish Jews. At the same time they were thriving in the East under the caliphs of Bagdad, whose favour they enjoyed, at least till towards the end of the tenth century.

Charlemagne protected the Jews like his other subjects: they filled municipal offices; they were physicians and bankers; and Isaac, a Jew, was chosen by that emperor as his ambassador to Harun al Rashid, caliph of Bagdad, a mission which was considered of the greatest importance at the time. The Jews enjoyed the same or even greater influence under Louis le Debonnaire and Charles the Bald, but towards the end of the latter reign the clergy began afresh to show their hostility. The Council of Meaux re-enacted the exclusion of the Jews from all civil offices; but it was under the third or Capet dynasty that the Jews suffered real persecution in France. Philippe Auguste, pressed by the wants of an empty exchequer, and perhaps also by the reports of fanatics, who charged the Jews with all sorts of crimes, banished, A.D. 1180, all the Jews from his dominions, confiscated their property, and declared all debts due to them to be annulled. About twenty years afterwards the Jews were allowed to re-enter France, which they did in great numbers. This was the beginning of a series of alternate proscriptions and relaxations, continued under the following reigns for about two centuries, until they were finally expelled under Charles VI.

In Germany about the same age they suffered under sudden bursts of popular fanaticism. They were massacred at the cry of 'Hep,' 'Hep,' the initials of the words 'Hierosolyma est perdita.' St. Bernard and Pope Eugenius III. loudly reprobated these atrocities. In Italy the Jews seem to have enjoyed greater, though not always uninterrupted security, but their safest asylum was Poland, where Casimir the Great allowed them considerable privileges, and where they formed the only middle order between the nobles and the serfs. It was in Spain and Portugal, after the expulsion of the Moors, that the proscription of the Jews was most sweeping and effectual. The regular Inquisition established under Ferdinand and Isabella undertook the task of punishing all relapsed converts. As for the unconverted Jews, the edict of 1492, made at the instigation of the Inquisitor Torquemada, banished them all from the kingdom. The number of Jews thus expelled from Spain has been vaguely estimated at half a million, and even 800,000. They were allowed to carry away or sell only their moveables. Few of them consented to embrace Christianity in order to remain. Soon afterwards they were driven away from Portugal also with circumstances of still greater barbarity. Many perished, and others took refuge on the African coast. The expulsion of the Jews and that of the Moors or Moriscoes drained Spain of its most useful subjects.

Throughout the dominions of the Sultan the Jews were allowed to settle and follow their trades, though looked upon with scorn by the Osmanlees. In the regencies of Barbary they settled likewise in great numbers.

During the eighteenth century a milder spirit of toleration manifested itself towards the Jews in several countries of Europe. Maria Theresa and Joseph I. gave them equal rights and subjected them to the same laws with the Christians. Frederic, called the Great, was not so liberal towards them, for he laid them under peculiar restrictions and disqualifications. In Holland they have long formed a highly flourishing, numerous, honourable, and intelligent community.

Napoleon in 1806 assembled a sanhedrim at Paris, and submitted to them twelve questions concerning the moral and social doctrines and discipline of the Jews. Their answers being found satisfactory, an ordinance was issued giving the Jews a regular organization throughout France, and placing them on the same footing as other Frenchmen. This system has remained unaltered. The king of Prussia and other German powers have followed the example. In Russia the Jews are subject to many restrictions, and especially the Rabbins.

The Jews in France are reckoned at 50,000; in Italy about 36,000; in the Austrian empire 520,000; in Prussia 135,000, in the rest of Germany 138,000; in Holland and and Belgium 80,000; in Great Britain 30,000; in Russia and Poland 658,000; in the Turkish dominions they have been vaguely estimated at 800,000; in Persia they are few and oppressed. There are communities of them at Bokhara and other parts of Tartary, in India, and even in China. In the United States they are reckoned at about 5000.

(Jost, *Allgemeine Geschichte des Israelitischen Volkes*; Millman, *History of the Jews*; Josephus; Basnage; Beer, *Geschichte aller Bestandenen und noch Bestehenden Religiösen Sekten der Juden*; Beugnot, *Les Juifs d'Occident.* Lindo's *Jewish Calendar* contains a Chronological Table, in which some of the dates differ from some of those given in this article.)

It does not appear at what time the Jews found their way to this island, but they were settled here in the Saxon period, and as early as A.D. 750. From the time of the Conquest the Jews in England rapidly increased in number. Under the first three Norman kings they lived undisturbed, so far as we are informed, and apparently acquired great wealth. But under Stephen and his successors they suffered grievously from the rapacity of the kings and the bigoted intolerance of the people. The cruel persecutions which they experienced from all persons, both lay and ecclesiastic, poor and rich, are fully attested, not by their own writers, but by the evidence of their enemies. Finally, in the reign of Edward I., about A.D. 1290, all the Jews were banished from the kingdom. Their numbers at that time are conjectured (but on what grounds we are not aware) to have been between 15,000 and 16,000. It was not till after the Restoration, A.D. 1660, that the Jews again settled in England; and though under the Protectorate they had entered into negotiations with Cromwell to obtain permission to enter the island, nothing seems to have been done in the matter, and those who have investigated the subject bring forward no proof of leave being formally granted to them to return. After the Restoration it seems probable that they came in gradually without either permission or opposition, and since that time foreign Jews have been on the same footing as other aliens with respect to entering the country. In the year 1753 an act was passed to enable foreign Jews to be naturalized without

taking the sacrament; but the act was repealed in the following session, under the influence of the popular feeling, which was most strongly opposed to the measure of 1753. Since this year no legislative act has passed with special reference to the Jews, and they have lived in the United Kingdom unmolested. It is said that the number of Jews in London alone is about 18,000, and in the rest of England about 9000. The number in Scotland and Ireland is probably small, but we are not aware that there is any good estimate as to their numbers in these parts of the United Kingdom.

During their residence in England, up to their banishment in the time of Edward I., the Jews were considered as the villains and bondsmen of the king, a relation which seems to explain the power over their persons and property which was assumed and exercised by the king in the most oppressive manner. They however could purchase and hold land, subject only to the right of the king, whatever it might be, to levy heavy taxes on them and seize their lands if they were not paid. By the act of the 55th of Henry III. the Jews were declared incapable of purchasing or taking a freehold interest in land, but might hold, as in time past they were accustomed to hold, houses in the cities, boroughs, and towns where they resided. Another act, 3 Edward I., forbade Jews from alienating in fee, either to Jew or Christian, any houses, rents, or tenements which they then had, or disposing of them in any way without the king's consent; they were permitted to purchase houses and curtilages in the cities and boroughs where they then resided, provided they held them in chief of the king; and they were further permitted to take lands to farm for any term not exceeding ten years; such permission however was not to continue in force for more than fifteen years from the date of the act. Since the time of their banishment no statute has been passed which in direct terms affects the right of the Jews to hold real estates in England; and it has been a matter of dispute whether they can now legally hold such estate. It has been contended that the act called the 55th Henry III. is not an act of parliament, but only an ordinance of the king, which however, to say the least, seems a very questionable proposition. Some Jews, we believe, do hold real estate, and it is contended by some that they are legally entitled to do so. It is out of the place here to discuss this question, and the reader is referred to the authorities at the end of the article.

The Jews are still incapacitated from being members of parliament and filling various offices in this country. The act of the 9th Geo. IV., c. 17, substitutes for the sacramental test a form of declaration to be made by every person, within one calendar month next before or upon his admission into any of the corporate offices mentioned in that act, or within six calendar months after his appointment to any place mentioned in the fifth section of that act. As this declaration contains the words 'upon the true faith of a Christian,' it has the effect of excluding Jews from corporate offices, and, in connection with the Abjuration Act, from places under government, so far as they are not relieved by the Annual Indemnity Act. The abjuration oath, which contains the same words, has the effect of excluding the Jews from parliament. (1 Geo. I., st. ii., c. 13; 6 Geo. III., c. 53.) Several attempts have been made, but hitherto unsuccessfully, to remove these impediments to the Jews being on the same footing as other British subjects.

It seems to be the general opinion that the Jews are within the benefit of the Toleration Act of the 1 William and Mary, as extended by the 53 George III., c. 160. The following disability is a singular one. It has been decided that a legacy given for the instruction of Jews in their religion is not one which will be supported by the Court of Chancery, though any other kind of charitable bequest for the benefit of Jews is valid. It is a vulgar error, still entertained by some people, that Jews, even if born in this country, are aliens. Perhaps it is hardly necessary to remark that they are British subjects, like any other persons who are born here.

(Blunt's *History of the Establishment and Residence of the Jews in England, with an Enquiry into their Civil Disabilities*, London, 1830; Goldsmid's *Remarks on the Civil Disabilities of British Jews*, London, 1830.)

JIDDA. [ARABIA.]

JIG, or GIGUE, an animated quick dance-tune, in six-eight time, to be found in the sonatas of Corelli, Handel, and other composers, till towards the middle of the eighteenth century. The *jig*, or at least the name, is unknown in modern music; though in a French work, of quite recent date, we are told that it is still in use in England.

JOAN, POPE, a supposed individual of the female sex, who is placed by several chroniclers in the series of popes between Leo IV. and Benedict III. about A.D. 853-5. The first who mentions the story is Marianus Scotus, a monk of the abbey of Fulda, who died at Mainz, A.D. 1086, and who says in his chronicle, under the year 853, the 13th year of the reign of the emperor Lotharius, that Leo IV. died on the 1st of August, and that to him succeeded Joan, a woman, whose pontificate lasted two years, five months, and four days, after which Benedict III. was made pope. But Anastasius, who lived at the time of the supposed Pope Joan, and who wrote the lives of the popes down to Nicholas I. who succeeded Benedict III., says, that fifteen days after Leo IV.'s death Benedict III. succeeded him. It is true that some manuscript copies of Anastasius, among others one in the king's library at Paris, contain the story of Joan, but this has been ascertained to be an interpolation of later copyists, who have inserted the tale in the very words of Martinus Polonus, a Cistercian monk and confessor to Gregory X., who wrote the lives of the popes, in which, after Leo IV., he places 'John an Englishman,' and then adds, '*Hic, ut asseritur*, fœmina fuit:' he then goes on to say that this Joan when a young woman left her home in man's disguise, with her lover, a very learned man, and went to Athens, where she made great progress in profane law; afterwards she went to Rome, where she became equally proficient in sacred learning, for which her reputation became so great that at the death of Leo she was unanimously elected as his successor, under the general belief of her male sex. She however became pregnant, and one day as she was proceeding to the Lateran Basilica, she was seized in child-labour on the road between the Colosseum and the Church of St. Clement, and there she died and was buried without any honours, after a pontificate of two years, five months, and four days. The story was generally copied from Martinus by subsequent writers, and Platina himself, in his 'Lives of the Popes,' repeats it on the authority of Martinus, adding various other reports concerning the 'sella stercoraria,' &c., and concluding with these words: 'The things I have above stated are current in vulgar report, but are taken from uncertain and obscure authorities, and I have inserted them briefly and simply, not to be taxed with obstinacy.' Panvinius, Platina's continuator, subjoins a very critical note, in which he shows the absurdity of the tale, and proves it to have been an invention. But the best dissertation on the subject is that of David Blondel, a Protestant, who completely refutes the story in his *Familier Eclaircissement de la question si une Femme a été assise au Siège Papal entre Leon IV. et Benoit III.*, Amsterdam, 1649. There are critics who contend that it is only the later MSS. of the 'Lives of the Popes' by Martinus Polonus which contain the tale of Pope Joan, and that those MSS. which were written during the life or soon after the death of Martinus do not contain it. It is evident however that the story was in circulation already in the 12th century, long before the time of Martinus, as Etienne de Bourbon de Belleville, a companion of St. Dominic, in his treatise 'De Septem Donis Spiritus Sancti,' under the head of 'Prudentia,' relates from 'the Chronicles' the story of Pope Joan, but places it about the year 1100, and says that on the discovery of her sex she was stoned to death by the people. These authorities prove at all events that the Protestants did not invent the tale of Pope Joan, as they have been accused of having done.

JOAN I. of Naples, daughter of King Robert of Naples, of the Anjou dynasty, succeeded her father in 1343. She was then only sixteen years of age, handsome, and accomplished. She had been married already some time to her cousin Andreas of Hungary, but their tempers and tastes did not sympathise together. Andreas claimed to be crowned king and to share his wife's authority, which, by the will of her father, had been left solely to her. His coarse and haughty manners offended the proud native barons, and the Hungarian guards which attended him excited their jealousy. A conspiracy was formed, and one night, while the court was at Aversa, the conspirators, who were of the nobles near his person, seized and strangled him, and threw his body out of a window of the castle. There seems little or no doubt that Joan knew of the plot, and that she did nothing to prevent the crime. As soon as it was per-

petrated she repaired to Naples, and thence issued orders for the apprehension of the murderers. Torture was employed to find out the conspirators, but the result of the interrogatories was kept secret. Many persons, high and low, were put to a cruel death, but public opinion still implicated the queen herself in the conspiracy. The same year Joan married her relative Louis, prince of Tarentum. Louis, king of Hungary, and brother of Andreas, came with an army to avenge his brother's death. He defeated the queen's troops, entered Naples, and Joan took refuge in her hereditary principality of Provence. She repaired to Avignon, and there, before Pope Clement VI., she protested her innocence and demanded a trial. The pope and his cardinals acquitted Joan, who, from gratitude, gave up to the papal see the town and county of Avignon. A pestilence in the mean time had frightened away the Hungarians from Naples, and Joan, returning to her kingdom, was solemnly crowned with her husband in 1351. Joan reigned many years in peace over her fine dominions. Having lost her second husband in 1362, she married a prince of Majorca, and on his death she married, in 1376, Otho, duke of Brunswick; but having no children by any of her husbands, she gave her niece Margaret in marriage to Charles, duke of Durazzo, who was himself related to the royal dynasty of Anjou, and appointed him her successor. Soon afterwards the schism between Urban VI. and Clement VII. broke out, and Joan took the part of the latter. Urban excommunicated her, and gave the investiture of the kingdom to Charles Durazzo, who, with the darkest ingratitude, revolted against his sovereign and benefactress; with the assistance of the pope he raised troops, defeated the queen, and took her prisoner. He tried to induce Joan to abdicate in his favour, but the queen firmly refused, and named as her successor Louis of Anjou, brother of Charles V., king of France. Charles then transferred Joan to the castle of Muro, in Basilicata, where he caused her to be strangled or smothered in her prison, in 1382, thirty-seven years after the death of her first husband Andreas.

JOAN II., daughter of Charles Durazzo, and sister of Ladislaus, king of Naples, succeeded the latter after his death in 1414. She was then forty-four years of age, and already noted for licentiousness and weakness of character. After her exaltation to the throne she continued in the same course, only with more barefaced effrontery. She however married, from political motives, James, count de la Marche, who was allied to the royal family of France; but the match, as might be expected, proved most unhappy. James was obliged to run away in despair from Naples, and retired to France, where it is said that he ended his days in a convent. Meantime unworthy favourites ruled in succession at the court of Joan. One of them, Ser Gianni Caracciolo, of a noble family, saw his influence disputed by the famous condottiere Sforza Attendolo, who, together with many barons that were jealous of Caracciolo, took the part of Louis of Anjou, a grandson of that Louis to whom Joan I. had bequeathed the crown. The queen sought for support in Alfonso of Aragon, king of Sicily, whom she adopted, and appointed her successor. Alfonso came to Naples, but the fickle Joan having made her peace with Sforza, revoked her adoption of Alfonso, and appointed Louis of Anjou as her successor. Alfonso was accordingly obliged to return to Sicily. The favorite Caracciolo was soon after murdered in consequence of court jealousy and intrigue. Louis of Anjou died also, and was followed to the grave by Joan herself, who, on her death, appointed René of Anjou as her successor. She died in 1435, leaving her kingdom in great disorder, and with the prospect of a disputed succession and a civil war. [ALFONSO V. of Aragon.]

JOAN OF ARC. [ARC, JOAN OF.]

JOA'NNINA, or YA'NINA, a city of Albania, situated in a valley in the heart of that province, on the south-western bank of a lake, from which a subterraneous stream flows into the Kalamá, the Thyamis (Θύαμις) of the antient Greeks. Joannina is in 39° 47′ N. lat., 20° 53′ E. long., according to the map prefixed to Colonel Leake's 'Travels in Northern Greece' (London, 1835). Its site is about 1000 feet above the level of the sea.

The origin and early history of this town are very obscure. In the later period of the Lower or Byzantine Empire it gradually became the chief city of that part of Greece which lay to the west of Mount Pindus. It is probably not very far from the site of the antient Dodona. In the seventh and following centuries, to the eleventh, the country around became a field of contention between the Byzantine Greeks and the Wallachians and Sclavonians, large colonies of whom settled in the district; but Joannina seems to have continued in the hands of the Greeks till the year 1082, when it was taken by the Normans under Bohemond (son of Robert Guiscard), who defeated the emperor Alexius Comnenus under the walls of the town. In the wars which subsequently desolated Western Greece it passed into the hands of the Frankish princes of the Ionian Islands, and in A.D. 1431 or 1432 into those of the Turks. In A.D. 1611 an unsuccessful attempt of the Albanian Greeks to throw off the Turkish yoke occasioned the expulsion of all Greeks from the old town, now termed the Castron (Κάστρον), or fortified part of Joannina. This led to the extension of the city along the banks of the lake on each side of the Castron, and subsequent tranquillity tended so far to its increase, that under the sway of the late Ali Pasha it contained a population of more than 40,000 inhabitants, chiefly Greeks, the remainder Moslems and Jews. It had two citadels (the Castron and the fortress of Litaritza), three palaces, nineteen mosques, five tekés, or Turkish monasteries, six Greek churches, one of them metropolitan, and two Jews' synagogues. There were an hospital, capable of receiving 150 patients, a prison, and two endowed colleges or schools, one of 300 scholars and one of 100, at which the antient languages were taught, and to which excellent libraries were attached. There were several smaller schools. The Greek spoken at Joannina was purer than in Greece Proper. The town was commercial rather than manufacturing: the chief commerce was carried on with Constantinople, Russia, Venice and Malta, and with the smaller towns and villages of Epirus, of which Joannina was the mart. The place was well supplied with turkeys and fowls, turtle-doves and beccaficos; fish and wild-fowl from the lake, and game from the neighbouring mountains. Little animal food was consumed, and ducks and geese were scarce. The climate is variable, and fevers, especially nervous, are common. The plain round Joannina yields fruit and grain of most kinds in vast abundance.

The lake of Joannina is in its greatest length twelve or fourteen miles measured from north-west to south-east; the greatest breadth is about five miles, the least about half a mile to a mile. It is bounded on the north-east by the Mitzikéli mountains (a branch of Pindus), which rise with very steep ascent to the height of 2500 feet above the lake; on the south-east by a rocky mountain of moderate height crowned with the extensive ruins of an antient Epirote city, which Colonel Leake considers it probable was the antient Dodona. On the south-west side of the lake is the plain of Joannina, and beyond that a range of low vine-covered hills. Opposite the town of Joannina is a small island on which is a fishing village, containing, in Ali's time, about two hundred houses: on this island were several convents, frequently used as state prisons; Ali, who had a house on it, kept a herd of red deer. The lake abounds with fish, among them are pike, perch, carp, tench and eels: some of them are of great size, sometimes weighing 24 or 25 lbs. avoirdupois; the eels are very fine, and sometimes of six or seven lbs. weight. Myriads of wild-fowl breed in the covert of the lofty reeds which surround the lake.

The lake is very commonly represented as divided into two parts, the north-western part being called the Lake of Lapsista, the south-eastern that of Joannina. But the middle part is rather a marsh than a lake, and is traversed by two long channels which connect the two portions of the lake. The Lake of Lapsista is much reduced in its dimensions in summer, and maize is grown on the desiccated ground. The waters of both lakes are absorbed by subterranean channels; that which communicates with the river Kalamá is in the Lake of Lapsista.

JOB, the Book of, is one of the poetical books of the Old Testament. Its title is taken from the patriarch Job ([illegible]) whose story it relates. Some critics have supposed, from the nature of the exordium, that Job was not a real person, and that the narrative in the book is fictitious. He appears however to be referred to as a real person by *Ezekiel* (ch. xiv., ver. 16), and *James* (ch. v., ver. 11); and the style of the book has all the circumstantiality of a real narrative. It has been inferred from his longevity (chap. xlii., 16), his holding the office of priest in his own family (chap. i., 5), his allusion to no other species of idolatry than the worship of the heavenly bodies (chap. xxxi. 26-28), the silence of the book respecting the history of the Israel-

tes and the Mosaic laws, and several incidental allusions to patriarchal customs, that Job lived in the patriarchal age. Dr. Hales has attempted, by astronomical calculations, to fix the exact time of Job's trial at 184 years before the birth of Abraham. (Hales's *Chronology*, vol. ii., pp. 55-7, 2nd edit.) There is a genealogy of Job at the end of the Septuagint version of this book, which makes him the fifth in descent from Abraham. Some critics have discovered what they consider proofs of a much later date in the book itself.

The scene of the poem is laid in the 'land of Uz' (עוץ), which, as Bishop Lowth has shown, is probably Idumæa.

The language is Hebrew, with a considerable admixture of Arabic, or, as others contend, of Aramaic.

The author is unknown. The arguments already stated with respect to the age at which Job lived are considered by most critics to prove the very high antiquity of the book. Lightfoot and others have supposed that Elihu was the author. This idea is founded chiefly on a translation of ch. xxxii., 16-17, the correctness of which is very doubtful. A very general opinion among critics ascribes it to Moses. Dr. Mason Good has concluded, from the character of the book, that the writer must have possessed certain qualifications of style, knowledge, country, and age, which are to be found in Moses alone. The same writer has collected a number of passages in which he sees a resemblance to the sentiments and style of Moses (Good's *Book of Job, Prelim. Disc.*, p. lvii., &c.) On the other hand Bishop Lowth remarks, that the style of Job differs widely from the poetical style of Moses, being much more concise, and more accurate in the poetical conformation of sentences. Several critics, among whom is Eichhorn, assign to the book a date earlier than the time of Moses. Schultens, Lowth, and others suppose Job himself, or some contemporary, to have been the author, and that the book fell into the hands of Moses while he lived in Idumæa, and was used by him to teach the Israelites patience and submission to the will of God, either during their bondage in Egypt, or in their subsequent wanderings. It is alleged that this hypothesis solves all the difficulties arising out of the internal character of the book, and accounts for its admission into the canon of the Hebrew Scriptures. Other critics assign a much later date to the book; several have ascribed it to Solomon, chiefly on the ground of a resemblance between certain passages in it and in the 'Proverbs.' Umbreit places it at the time of the Babylonish captivity (Umbreit's *Version of the Book of Job*, in the *Biblical Cabinet*, Introduction).

The canonical authority of the Book of Job is fully established by frequent quotations from it, both in the Old and New Testament. Several examples are pointed out in the notes to Good's version.

The design of this book appears to be to teach patience under suffering from the doctrine of a Divine Providence governing all things. It consists of a controversy between Job and three friends who came to visit him in his distress, on the question whether men enjoy prosperity or suffer adversity in this life according as their actions are good or wicked. At ch. xxxii. a new disputant is introduced in the person of Elihu, who reproves both parties for the sentiments they had expressed; and at length the dispute is decided by the interposition of God himself. The integrity of Job, which his friends had called in question on account of his calamities, is vindicated; and he is restored to possessions twice as great as he had before his trial. (Compare *James*, v., 10, 11.)

(The *Introductions* of Eichhorn, Jahn, De Wette, and Horne; Dr. Mason Good's *Translation of the Book of Job*; Lowth's *Lectures on the Sacred Poetry of the Hebrews*, lectures xxxii., xxxiii. For a list of Commentators see Watt's *Bibliotheca Britannica*.)

JOEL (יואל, Ἰωήλ), one of the twelve minor Hebrew prophets. In the first verse of the first chapter of his prophecy we are told that he was the son of Pethuel. Beyond this we have no certain information respecting him. The pseudo-Epiphanius states that he was born at Beth-horon, on the confines of Judah and Benjamin. He prophesied in the kingdom of Judah, but in what reign is uncertain. The most probable opinion is that which places his prophecy in the reign of Uzziah, contemporary with Amos and Hosea, between 800 and 780 B.C. He appears to refer to the same events as Amos (compare *Joel*, ch. i. with *Amos*, ch. iv., 6-9, and *Joel*, ii., 4-6 with *Amos*, i., 9, 10); and he does not mention the Assyrians or the Babylonians among the enemies of Judah, but only Egypt and Edom (ch. iii., 19). Other opinions have referred him to the reign of Joram (B.C. 895—883), and to that of Manasseh (B.C. 697—642).

The prophecy of Joel may be divided into two parts. In the first he describes a famine caused by the ravages of insects, and exhorts the people to repentance; denouncing still greater judgments if they continue impenitent, and promising the return of prosperity and plenty if they attend to his warning. The second part, beginning at ch. ii., ver. 28, alludes to events much more remote. The prophetic passage in ch. ii., ver. 28-32, is quoted by the apostle Peter as accomplished by the miraculous gift of tongues on the day of Pentecost (*Acts*, ii. 17-21). The remainder of the prophecy is supposed to be at present unfulfilled.

The canonical authority of this book has never been disputed. It is established by other quotations in addition to the remarkable one just mentioned.

Bishop Lowth (*Prælect.*, xxi.) remarks on the style of Joel: 'He is elegant, perspicuous, copious, and fluent; he is also sublime, animated, and energetic. In the first and second chapters he displays the full force of the prophetic poetry, and shows how naturally it inclines to the use of metaphors, allegories, and comparisons. But while we allow this just commendation to his perspicuity both in language and arrangement, we must not deny that there is sometimes great obscurity observable in his subject, and particularly in the latter part of the prophecy.'

(Rosenmüller's *Scholia*; Horne's *Introduction*; and list of commentators in Watt's *Bibliotheca Britannica*.)

JOHANNA. [ANZUAN.]

JOHANNISBERG. [NASSAU.]

JOHN, SAINT, THE BAPTIST, son of Zachariah, a Jewish priest, and Elizabeth his wife, who was a near relation of Mary the mother of Jesus Christ, was born to them in their old age. The sacred office was assigned to him of being the precursor or herald of the Messiah. The history of the public ministry of Jesus begins with the acts of John the Baptist, whom we find withdrawing himself from the ordinary affairs of life and retiring to the desert country watered by the Jordan, where he preached in a fearless manner against the vices of the age, urged an immediate repentance, enforcing his exhortations by the announcement that the Kingdom of Heaven was at hand, and requiring of those who professed to receive him as their instructor that they should submit to the rite of baptism.

Amongst those who came to him and were baptized by him was Jesus Christ, who at his baptism was announced, both by the Baptist himself and by a voice from heaven, to be the Son of God, the Messiah.

From this time we hear little more of John till we find him in prison. He had ventured publicly to reprove Herod the king for an act of great immorality. Herod had married Herodias who was the wife of Philip, tetrarch of Idumæa, his own brother. The Baptist's reproof was resented more violently by Herodias than by Herod. The history is related by the Evangelists with all particulars. Salome, the daughter of Herodias, had so pleased Herod with her dancing at a public entertainment given by him, that he in an Oriental affluence of professed obligation said publicly, that he [illegible] give her whatever she would ask, even to the half of his [illegible] The little girl, for she was then extremely young, instruct[illegible] wicked mother, asked the head of John the Baptist. [illegible] immediately sent to the prison in which John was con[illegible] beheaded him, and delivered the head to the young princess, [illegible] it in a dish to her mother.

JOHN, SAINT, THE APOSTLE AND EVAN[illegible]LIST. Among the persons who at the commencement of his ministry joined themselves to our Saviour were two brothers, named James and John, the sons of Zebedee. They were both admitted by him into the number of his Twelve Apostles, and John was throughout distinguished by him with peculiar marks of regard. He speaks of himself, in the account which he left of the ministry of Jesus, as the disciple whom Jesus loved: and whenever a very few only of the apostles were to be employed by Jesus, or to accompany him, John was always one of the number, James and Peter being usually the others.

At the Last Supper we find him leaning on the bosom of Jesus. He attended Jesus in the garden and in the hall of the high-priest. He accompanied him to Calvary, and when Jesus was hanging on the cross John drew near, and

while the miraculous darkness struck fear into the hearts of those who were employed in the work of death, he entered into conversation with Jesus, who commended to him the care of his mother Mary. This dying request of our Lord the apostle seems to have regarded as a sacred injunction, for he took her from that time to his own house.

After the resurrection of Jesus he was again distinguished by his notice; and when Jesus had ascended to heaven, and the interests of the Gospel were committed especially to those who had been chosen by him out of the world, John became one of the leading persons in the church; acting in concert with the other apostles, and especially Peter and James, till the history in the 'Acts of the Apostles' ceases to notice what was done by the other apostles, and is confined to the travels and labours of Saint Paul.

Saint John's labours in the church were chiefly among the inhabitants of Syria and Asia Minor, and no doubt he had a large share in planting Christianity in those provinces, where for a time it flourished greatly. But Christian antiquity does not present to us many particulars of the labours of the apostles, and we learn from it respecting John little more on which dependence may be safely placed, than that he resided at Ephesus in the latter part of his life, and died in extreme old age.

Two pleasing stories are related of him by early Christian writers, deserving of regard: one, that when too feeble to do more, he was wont to be carried into the assemblies of Christians at Ephesus, saying, as he went along, 'My little children, love one another.' The other respects his conduct to a young man who had joined a party of banditti. But when we read in those writers that he was thrown into a cauldron of boiling oil and came out unhurt, distrust arises, and we question the sufficiency of the evidence.

There is however little reason to doubt that he was at one period of his life banished to the island of Patmos, and that there he wrote the book called the 'Apocalypse,' or 'Revelation.'

There are also preserved three Epistles of his: but the most valuable of his writings which have descended to our time is the 'Gospel according to Saint John.' This Gospel is unlike the other three in several respects, and is supposed by those who have considered it to have been written with some especial purpose, either as a kind of supplement to the other Evangelists, which was the opinion of Eusebius, or with a view to the refutation of certain erroneous notions respecting our Saviour which had begun to prevail before the long life of Saint John was brought to a close. But with whatever design it was composed, it must ever be regarded as amongst the most valuable testimonies to the life, character, and doctrine of Jesus.

JOHN, king of England, surnamed Sansterre, or Lackland, a common appellation of younger sons whose age prevented them from holding fiefs, was the youngest of the five sons of Henry II. by his queen Eleanor of Guienne, and was born in the King's Manor House at Oxford, 24th December, 1166. In his youth he was created by his father earl of Montague in Normandy; and in 1176 he was contracted in marriage to Johanna (or Hadwisa, as she is called by some authorities), the youngest daughter of William earl of Gloucester (son of the great Earl Robert, natural son of Henry I.), who thereupon made Johanna his sole heir. The marriage was actually celebrated, 29th August, 1189. Henry, having after his conquest of Ireland obtained a bull from the pope authorising him to invest any one of his sons with the lordship of that country, conferred the dignity upon John in a great council held at Oxford in 1178. In March, 1185, John went over to take into his own hands the government of his dominions; but the insolent demeanor of the prince and his attendants so disgusted and irritated the Irish of all classes, that his father found it necessary to recal him in the following December. John however was his father's favourite son, in part perhaps from the circumstance that his youth had prevented him from joining in any of the repeated rebellions of his brothers; and it is said, that a suspicion began to be at last entertained by Richard, when, of the five brothers, he and John alone survived, that Henry intended to settle the crown of England upon the latter. According to this story, it was chiefly to prevent such an arrangement that Richard, joining Philip of France, flew to arms in January, 1189; but if so, it is difficult to account for the fact that John himself was found to be upon this occasion in confederacy with his elder brother, a discovery which was only made by their heart broken father upon his deathbed. [HENRY II.]

No opposition was offered by John to the accession of Richard, who endeavoured to attach him by the gift of such honours and possessions as amounted almost to sharing the kingdom with him. In addition to his Norman earldom of Montague, and that of Gloucester, which he acquired by his marriage, those of Cornwall, Dorset, Somerset, Nottingham, Derby, and Lancaster were bestowed upon him, so that there was thus placed under his immediate jurisdiction nearly a third of England. Richard however had not been long absent when his ambitious brother proceeded to take his measures for at least securing the crown to himself in case of the king's death, if not for an earlier seizure of it. The person next in the regular line of succession was Arthur, duke of Brittany, the son of John's elder brother Geoffrey, an infant of little more than two years old at the accession of Richard, who however recognised him as his heir, and had desired that his rights should be maintained by William de Longchamp, the bishop of Ely, whom during his absence he left in charge of the government. John accordingly directed his first efforts to the removal of the bishop, which, having obtained the co-operation of a strong party of the barons, he at length accomplished by actual force, in October, 1191. When the intelligence of Richard's captivity arrived in 1193, John at once openly took steps for the immediate usurpation of the throne. Repairing in haste to Paris, he secured the aid of Philip Augustus by the surrender of part of Normandy, and then, returning to England, proceeded to collect an army for the maintenance of his pretensions. In this attempt however he was successfully resisted by the loyal part of the nobility; and he also failed in his endeavours to induce the emperor, by the promise of a large bribe, to retain his brother in prison. On the return of Richard to England, in March, 1194, John's castles and estates were seized by the crown, and he and his chief adviser, Hugh, bishop of Coventry, were charged with high treason. John fled to Normandy, whither he was followed by the king at the head of an army; but the traitor made his peace by an abject submission, and, his mother seconding his supplications for pardon, he was allowed to retain his life and his liberty, and even restored to some measure of favour, though the restitution of his castles and territorial possessions was for a time firmly refused. Even that however was at length granted to his importunities and those of his mother; and it is further said, that Richard, when on his deathbed, was induced to declare John his successor.

John was present when Richard expired at Chaluz, 6th April, 1199, and before visiting England he hastened to secure the submission of the various continental territories of the crown. Upon repairing to Anjou, and the other original possessions of the Plantagenets, he found the prevalent feeling strongly in favour of his nephew Arthur; but both in Normandy, and also in Poitou and Aquitaine, where his mother's influence was predominant, his pretensions were readily acknowledged. Meanwhile in England, by the activity of the justiciary Fitz-Peter, a unanimous resolution to receive him as king had been obtained from a great council held at Northampton. Soon after this John made his appearance in person; and he was solemnly crowned at Westminster, on the 26th of May, the festival of the Ascension. The years of his reign are reckoned from Ascension-day to Ascension-day.

Philip Augustus having, for his own purposes, espoused the cause of Arthur, whom he had got into his possession, soon overran both Normandy and Anjou; but in May, 1200, John purchased a peace by a heavy pecuniary payment and the cession of several towns and other territories to the French king, who on his part relinquished such of his conquests as were not thus permanently made over to him, and also compelled Arthur to do homage to his uncle for Brittany. The next year John, having become tired of his wife, or never having been attached to her, procured a divorce on the plea of consanguinity, and married Isabella, daughter of Aymar count of Angoulême, who had already been betrothed, and even privately espoused, to Hugh count of La Marche. The complaints of the count in consequence of this injury gave Philip such a pretence as he wanted for renewing the war: he immediately took Arthur again by the hand, and putting him forward as the legitimate lord of the old fiefs of the Plantagenets, rapidly obtained possession of all the most important towns and places of

strength in those countries. Arthur however, while he was besieging the castle of Mirabeau in Poitou, which was held by John's mother, Queen Eleanor, was taken captive by his uncle (1st August, 1202): the unfortunate young prince was immediately consigned to close custody in the castle of Falaise, from which he was soon after removed to Rouen, and having never been seen more, was universally believed to have been there put out of existence by his uncle's order. Indeed, it was generally said that he had been murdered by John's own hand, an imputation which the latter never took the trouble to deny. Arthur's sister Eleanor, to whom devolved his claim to the inheritance of the English crown, was carried over to England, and confined in the castle of Bristol, in which prison she remained till her death in 1241. Notwithstanding the capture of Arthur however, the war in France went wholly against John; and before the end of the year 1204 Normandy, Anjou, Maine, and Touraine were rent from the crown of England, and re-annexed to that of France, from which they had been separated for nearly three centuries. Two years afterwards John made an unsuccessful attempt to recover what he had thus lost.

While still at war with France, John became involved in another contest at home, which was eventually attended with still more fatal results. By insisting upon the right of the crown to nominate the archbishop of Canterbury, on that see becoming vacant in July, 1205, he drew upon himself the formidable hostility of the whole body of the national clergy, and also of the able and imperious pontiff who then presided over the Western Church. [INNOCENT III.] John paid little regard either to the interdict under which his kingdom was laid in 1208, or to the bull of excommunication issued against him the following year, or even to that deposing him and absolving his subjects from their allegiance, which Innocent launched at him in 1212. In the midst of all this ecclesiastical thunder he chastised the Scottish king William, compelling him, in 1209, to avert further hostilities by the payment of a large sum of money, and the delivery of his two daughters, with other hostages, as pledges for his observance of his engagements; he passed over to Ireland in 1210, and reduced a rebellion of the English chieftains there; and in 1212 he marched into Wales, and compelled Llewellyn, the prince of that country, to make his submission. In the last-mentioned year he also put down a confederacy of certain of his barons, which had been formed with the object of seizing his person.

At last however Innocent had recourse to more effective arms than his apostolic artillery. At the instigation of the pope, Philip Augustus prepared to invade England; and though John at first attempted to meet this threatening danger with some spirit, by conducting an army to France in April, 1213, he soon returned home without having done anything; and in the despair produced by the universal hatred in which he found himself to be held by his subjects, whom his lawless and oppressive government had long alienated and disgusted, he consented, at Dover, 13th May, 1213, in an interview with Pandulf, the papal legate, to submit to all the demands of the holy see, of which the admission of the pope's nominee, Stephen de Langton, to the archbishopric of Canterbury, was the first. Two days after he made over to the pope the kingdoms of England and Ireland, to be held of him and of the Roman Church in fee, and took to his holiness the ordinary oath taken by vassals to their lords. It was now agreed that there should be an oblivion of the past on both sides, that the bull of excommunication should be revoked by the pope, and that of John's disaffected English subjects those who were in confinement should be liberated, and those who had fled or been banished beyond seas should be permitted to return home. Philip, whose ambition was mortified by this pacification, would have persisted in his project of invasion, even in opposition to the express commands of the pope, but he was compelled to disband his army by the result of a battle fought in June, between the English and French fleets, in the harbour of Damme, the first great victory in the naval annals of England, in which 300 of his vessels were captured, above 100 burned, and all his military stores and provisions, as well as his means of conveyance, taken from him.

One effect of this victory however was immediately to beget in John a hope of being able to extricate himself from his late engagement in favour of the exiles and outlaws, and perhaps also from the vassalage in which he had bound himself and his kingdom to the pope. In this view he at first attempted to raise an army with which to invade France, before doing anything in fulfilment of his promises either to the barons or the Church; but finding that the opposition of these united powers was too strong for him, he changed his course of proceeding, and temporised with both, until, by further submissions to the new papal legate, the Cardinal Nicholas, who arrived in England in the end of September, if he did not gain over the national clergy, he at least converted the pope himself, from being the head of the confederacy against him, into his friend and supporter. The Primate Langton however, greatly to his honour, still continued to make common cause with the barons. Langton had already, in a meeting held at St. Alban's, 25th August, proposed to the barons to rally round the charter of Henry I., and had solemnly sworn them to hazard their lives in the maintenance of the rights and liberties therein recognised. For a short time the commencing strife was appeased by an award of the pope; soon after which, in June, 1214, John hastened over to France, where however the great victory of Bouvines, gained by Philip, 27th July, over the allied army of the English under John's bastard brother, the earl of Salisbury, the forces of the emperor, of the earl of Flanders, and of the earl of Boulogne, compelled the English king to sue for a cessation of hostilities. On the 19th October a truce was arranged between the two kingdoms, to last for five years. But the depressed state of John's affairs now presented to his barons an opportunity for the renewal of their demands, of which they hastened to avail themselves. Their first memorable assemblage, in which they concerted their plans, was held, under pretence of celebrating the festival of the Saint, in the abbey of St. Edmund at Edmondsbury, on the 20th of November. Before they separated they advanced one by one to the high altar, and laying their hands upon it, took a solemn oath to withdraw their fealty, and levy war upon John, if he should refuse their demands, and never to lay down their arms till they had obtained from him a charter confirming the national liberties. Their petition was formally presented to John in the Temple, at London, on the feast of the Epiphany, the 6th of January following. On its rejection, both parties, after an appeal to the pope, who at once took the part of John, prepared for war. In the beginning of May, 1215, the barons having mustered their forces, which they put under the command of Robert Fitzwalter, and designated by the title of the army of God and of his Holy Church, proceeded to lay siege to the castle of Northampton. After wasting a fortnight however they were obliged to retire from this fortress; but having then marched to London, they were gladly received by the citizens, 17th May, and immediately took possession of the town. On this John consented to a conference, and the celebrated meeting on the plain of Runnymead, which lay about half-way between London and Odiham, in Hampshire, whither John had retired, was held in consequence on Trinity Monday, the 15th June. The result was, the concession and signature by John of the Great Charter, embodying all the barons' demands. [MAGNA CHARTA.]

Scarcely however had the charter been thus extorted, when John set himself to work to endeavour to escape from its obligations. The suspicions excited by his general conduct, and especially by his introduction into the kingdom of numerous bodies of foreign troops, again called up the barons in arms by the following October. At first the new contest ran strongly in favour of the king; William D'Albiney, who, by the direction of the insurgent leaders, had thrown himself into the castle of Rochester, was, after sustaining a siege of seven weeks, compelled to surrender at discretion: news soon after arrived that the pope, as requested by John, had annulled the charter; this intelligence was followed by other papal bulls suspending Archbishop Langton, excommunicating the chiefs of the barons by name, and laying the city of London under an interdict; and John was soon enabled to wreak his vengeance on his enemies almost without encountering any resistance. While one part of his army, under the command of the earl of Salisbury, wasted the counties around the metropolis, where the chief strength of the barons lay, he himself, with another force, proceeded to the north, where he drove back their ally, Alexander, the young king of Scotland, pursuing him as far as Edinburgh, and reducing to ashes every town, village, and castle, on both sides of the border, that fell within the range of his furious progress. In these

disastrous circumstances, the barons congregated in London resolved, after much debate, upon the desperate expedient of offering the crown to Louis, the dauphin of France, as the only chance left to them of preserving any part of the national liberties. Accepting the invitation, Louis set sail from Calais with a fleet of six hundred and eighty sail, and, on the 30th of May, 1216, landed at Sandwich. John retired to the west at his approach, and the French prince, after attacking and easily reducing the castle of Rochester, immediately marched to the capital. The fortune of the contest now turned. The people in all parts of the country eagerly rallied around Louis; even his foreign auxiliaries, most of whom were Frenchmen, began to quit the standard of the English king, and either to join that of the invader or to return home. At this critical moment arrived the news of the death of John's powerful friend Pope Innocent III. (16th July). Still however most of the places of strength were in his hands; and some months were spent to little purpose by the adverse party in attempts to reduce Dover, Windsor, and other castles which were occupied by his garrisons. Meanwhile, in the disappointment produced by the protraction of the war, jealousy of their foreign allies was beginning to spread among the insurgents; and it is very doubtful what the issue of the struggle might have been if the life of John had been prolonged. But on the 14th of October, as he was attempting to ford the Wash at low-water, from Cross-keys to the Foss-dyke, and had already got across himself with the greater part of his army, the return of the tide suddenly swept away the carriages and horses that conveyed all his baggage and treasures; on which, in an agony of vexation, he proceeded to the Cistercian convent of Swineshead, and was that same night seized with a violent fever, the consequence probably of irritation and fatigue, but which one account attributes to an imprudent indulgence at supper in fruit and new cider; another to poison administered to him by one of the monks. Although very ill, he was conveyed the next day in a litter to the castle of Sleaford, and thence on the 16th to the castle of Newark, where he expired on the 18th, in the forty-ninth year of his age, and the seventeenth of his reign.

All our historians paint the character of John in the darkest colours; and the history of his reign seems to prove that to his full share of the ferocity of his race he conjoined an unsteadiness and volatility, a susceptibility of being suddenly depressed by evil fortune and elated beyond the bounds of moderation and prudence by its opposite, which give a littleness to his character not belonging to that of any of his royal ancestors. He is charged in addition with a savage cruelty of disposition, and with the most unbounded licentiousness: while on the other hand so many vices are not allowed to have been relieved by a single good quality. It ought to be remembered however that John has had no historian; his cause expired with himself, and every writer of his story has told it in the spirit of the opposite and victorious party. In regard to what has generally been accounted the act most decisive of the baseness of his character, his surrender of his kingdom in vassalage to the pope, we may observe that Dr. Lingard has lately advanced some considerations tending to show that it does not deserve to be viewed in the light in which it has been usually regarded.

The children of John by his queen Isabella of Angoulême were:—1. Henry, who succeeded him as Henry III.; 2. Richard, born January 5, 1208, created earl of Cornwall 1226, elected king of the Romans 1257, died 2nd April, 1272; 3. Joan, married June 25, 1221, to Alexander II. of Scotland, died March 4, 1238; 4. Eleanor, married, first, 1235, to William Marshall, earl of Pembroke, secondly, 1238, to Simon Montfort, earl of Leicester; and 5. Isabella, born 1214, married 20th July, 1235, to Frederic II., emperor of Germany, died 1st December, 1241. Several natural children are also assigned to him, none of whose names however make any figure in our history.

JOHN OF GAUNT. [EDWARD III.; HENRY IV.]

JOHN, Kings of Portugal. [PORTUGAL.]

JOHN OF SALISBURY finds a place, and very deservedly, in every catalogue of learned Englishmen. His æra was the reign of King Henry II., which, according to a very common but an incorrect mode of speaking, is called a dark age; for an age cannot possibly be dark which had such men living in it as this John, Peter of Blois, Thomas à Becket, and many others, especially historians, whose writings still remain to show what kind of men they were, and to attest the great extent of their reading and the general intellectual power which they had acquired. John had studied at Oxford, but he visited also the universities of France and Italy. In fine, if we may trust Leland, an excellent authority, he was intimately acquainted with the Latin and Greek writers; he had some knowledge of Hebrew; he was skilled in the mathematics and every branch of natural philosophy, as he was also in theology and morals; he was an eloquent orator and an eminent poet. Leland further says of him that he was possessed of the most amiable dispositions, ever cheerful, innocent, and good.

He was much connected with Becket, archbishop of Canterbury, the murder of whom is one of the dark stains on the reign of Henry II. Peter of Blois, in the twenty-second of his Epistles, which are collected and printed, calls John the eye and hand of the archbishop. John became himself bishop of Chartres in 1164. He died in 1182.

His principal historical writings were Lives of two archbishops of Canterbury, Anselm and Thomas à Becket. But the work by which he is best known to scholars, for the curious matter which it contains can scarcely be said to have found its way into the vernacular literature of his own or any other country, is entitled 'Polycraticon, de Nugis Curialibus et Vestigiis Philosophorum,' in which he describes the manners of the great, speaking not unfrequently in the style of sharp satire. There is an edition of it at Paris, 1513, and another at London, 1595. A large catalogue of his writings may be seen in Pitz and other writers of that class.

Mr. Berington has devoted several pages to John of Salisbury in his 'Literary History of the Middle Ages,' 1810, pp. 315-320.

JOHN HYRCA'NUS. [HYRCANUS, JOHN.]

JOHN I., a native of Tuscany, succeeded Hormisdas in the see of Rome, A.D. 523. He was employed by King Theodoric on a mission to the Emperor Justin of Constantinople; but after his return, from some unknown cause, he incurred the displeasure of Theodoric, and was put in prison, where he died, A.D. 526.

JOHN II. succeeded Boniface II. A.D. 532, being elected by the clergy and the people of Rome, and confirmed by King Athalaric, for which confirmation a certain payment was fixed by an edict of the same king. He died in 535.

JOHN III., a native of Rome, was elected to succeed Pelagius I. in the year 560, and was confirmed by the exarch of Ravenna in the name of the Emperor Justinian. Two French bishops, of Embrun and of Gap, having been deposed by local councils, appealed to John, who ordered their restoration, which Gontram, the Burgundian king, enforced in opposition to the French clergy, who asserted their independence of the Roman see. (Dupin, *De Antiqua Eccles. Discipl.*) John died in 574.

JOHN IV., a native of Dalmatia, succeeded Severinus in 640. He condemned the heresy of the Monothelites [EUTYCHIANS], and died in 642.

JOHN V., a native of Syria, succeeded Benedict II. in 686, and died after a few months.

JOHN VI., a native of Greece, succeeded Sergius I. in 702. In a council which he held at Rome he acquitted Wilfred, archbishop of York, of several charges brought against him by the English clergy. He died in 705.

JOHN VII., also a Greek, succeeded John VI., and died in 707.

JOHN VIII., who has been styled the IX. by those who believed in the story of Pope Joan, whom they style John VIII. [JOAN, POPE], succeeded Adrian II. in 872. He crowned Charles the Bald emperor, and after him also Charles the Fat. He confirmed the exaltation of Photius to the see of Constantinople. He had disputes with the marquises of Tuscany and the dukes of Spoleto, and died in 882, after a busy pontificate.

JOHN IX. was elected in 898, held two councils at Rome and Ravenna, and died about the year 900.

JOHN X. succeeded Lando in 915. He crowned Berengarius as king of Italy and emperor. The Saracens from Africa, who had landed in Italy and fortified themselves near the banks of the Liris, made frequent irruptions into the Roman territory. John, united with Berengarius and the dukes of Benevento and Naples, marched in person against them, and completely routed and exterminated them. The famous Marozia, a Roman lady of very loose

conduct, and her husband, Guido, duke of Tuscany, ruled at Rome by force and intrigue. John, having had repeated disputes with them, was at length seized by their satellites in his palace of the Lateran, and thrown into prison, where he was put to death, according to report, A.D. 927.

JOHN XI., son of Marozia, succeeded Stephen VIII. in 931. His brother Alberico headed a revolt of the Romans against his mother, who was secured in prison, and her new husband King Hugo was driven away from the city. John himself was closely watched by his brother, and died in the year 936, not without suspicion of violence.

JOHN XII., originally called Octavianus, son of Alberico and grandson of Marozia, succeeded Agapitus in 956, while he was only in his 19th year. In 960 he crowned at Rome Otho I. of Germany as emperor and king of Italy. But some time after the complaints against his licentious conduct became so loud, that the emperor returned to Rome, and there in an assembly of the clergy caused John to be deposed and Leo VIII. to be elected in his stead, in 963. In the following year however John re-entered Rome at the head of numerous partisans, drove out Leo, and committed many acts of cruelty. Otho, who was then in the north of Italy, was preparing to return to Rome at the head of his troops, when John fell suddenly ill, and died in 964. Panvinius, in a note to Platina's account of Pope Joan, suggests that the licentiousness of John XII., who among his numerous mistresses had one called Joan who exercised the chief influence at Rome during his pontificate, may have given rise to the story of 'Pope Joan.'

JOHN XIII., bishop of Narni, succeeded Benedict V. in 965, with the approbation of the emperor Otho, but soon after the Romans revolted and imprisoned John. Otho however marched to Rome, reinstated John, and hanged thirteen of the leaders of the revolt. John crowned at Rome Otho II., son and successor of Otho I., and died in 972.

JOHN XIV., bishop of Pavia and chancellor to Otho II., succeeded Benedict VII. in the see of Rome in 983. Boniface VII., an intruder, entered Rome soon after, and put John in prison, where he died of violence, after a pontificate of only nine months.

JOHN XV. (styled XVI. by some who place before him another John, who is said to have lived only a few days after his election) was elected in 985. The disturbances of the patrician or consul Crescentius began in his pontificate. John however remained at Rome, and kept on good terms with Crescentius. He died in 996.

JOHN XVII., a Calabrian and bishop of Piacenza, was appointed pope in 997 by Crescentius, in opposition to Gregory V., but Otho III. came to Rome, imprisoned and mutilated John, and put to death Crescentius and his partisans. [GREGORY V.] John however is generally numbered in the series of the Popes.

JOHN XVIII. succeeded Sylvester II. in 1003, and died four months after his election.

JOHN XIX. succeeded the preceding, and died about 1009. The history of the popes during this period is very obscure, and the chronology confused.

JOHN XX., son of Count Gregory of Tuscany, succeeded his brother Benedict VIII. in the year 1024. He crowned the Emperor Conrad, and died in 1034.

JOHN XXI., a native of Lisbon, succeeded Adrian V. in 1277, and died about three months after.

JOHN XXII., James of Cahors in France, succeeded Clement V. in 1316, and, like him, took up his residence at Avignon. He was a man of considerable abilities, but he has been taxed with avarice and worldliness. The crown of Germany was then contested between Louis of Bavaria and Frederic of Austria, and John, assuming the right of deciding, excommunicated Louis. But this measure produced little effect in Germany; the diet of Frankfort declared that the imperial authority depended upon God alone, and that the pope had no temporal authority, direct or indirect, within the empire. In Italy however John met with greater success; his ally, Robert, king of Naples, defeated the Guibelines, and the pope excommunicated Matteo Visconti, the great leader of that party, and likewise Frederic, king of Sicily. Between Guelphs and Guibelines, Italy was at that time in a dreadful state of confusion. The pope preached a crusade against Visconti, Cane della Scala, and the Este, as heretics. Robert, with the assistance of the pope, aspired to the dominion of all Italy, and the pope sent a legate, who, at the head of an army, assisted Robert and the other Guelphs against the Guibelines of Lombardy. But the Guibelines had clever leaders; Castruccio Castracani, Cane della Scala, and the Visconti kept the fate of the war in suspense, and Louis of Bavaria sent troops to their assistance. Louis came himself to Italy in 1327, and after being crowned at Milan with the iron crown, he proceeded to Rome, where the Colonna and other Guibelines roused the people in his favour, and drove away the papal legate. Louis was crowned emperor in St. Peter's by the bishops of Venice and of Aleria, after which he held an assembly in the square before the church, in which he summoned James of Cahors (meaning the pope) to appear to answer the charges of heresy and high treason against him. After this mock citation, the emperor proceeded to depose the pope and to appoint in his stead Peter de Corvara, a monk of Abruzzo, who assumed the name of Nicholas V. Louis also proclaimed a law, which was sanctioned by the people of Rome, to the effect that the pope should reside at Rome, and if absent for more than three months, should be considered as deposed. Louis now returned to the north of Italy, and thence to Germany. Castruccio and Cane della Scala died, and the Guelphs and the papal legate began to resume the preponderance. In 1334 John XXII. died at Avignon, leaving the affairs of Italy as embroiled as ever, and 18 millions of golden florins in his coffers, besides jewels. It was under his pontificate that the clergy and people of the towns were deprived of the right of electing their bishops, which right he reserved to himself, on payment of certain fees by the person elected. He was also the inventor of the ANNATES, or FIRST FRUITS.

JOHN XXIII., Cardinal Cossa, succeeded Alexander V in 1410. He supported the claims of Louis of Anjou against Ladislaus, king of Naples; but the latter, having defeated his rival in battle, advanced to Rome, and obliged the pope to escape to Florence. John preached a crusade against Ladislaus, which gave occasion to denunciations and invectives from John Huss. Meantime the great schism continued, and Gregory, styled XII., and Benedict, antipope, divided with John the homage of the Christian states. John in his exile, wishing to secure the favour of the Emperor Sigismund, proposed to him the convocation of a general council to restore peace to the church, and Sigismund fixed on the city of Constance as the place of assembly. On hearing of the death of Ladislaus, by which event Rome became again open to him, John repented of what he had proposed, but was obliged to comply with the general wish by repairing to Constance. The fathers of the council decided that John, as well as his two rivals, should renounce their claims to the papacy as the only means of restoring peace. John signed the form of renunciation, but soon after, by the assistance of Frederic of Austria, he was conveyed out of the city, and resumed his authority by ordering the council to dissolve. But the council, in its fourth and fifth sessions, decided by a solemn decree that the general council once assembled is superior to the pope, and can receive no orders from him. A formal process being instituted against John, sixty charges were laid against him, of which only part were made public. Witnesses being heard, a solemn deposition was pronounced on the 29th May, 1415, to which John submitted, and was then given into the custody of the elector palatine. After the election of Martin V. and the termination of the council of Constance, John, now again Balthazar Cossa, escaped from Germany, and made his submission to the new pope, who treated him kindly and gave him the first rank among the cardinals. He died soon after.

JOHN'S COLLEGE, ST., OXFORD, was founded by Sir Thomas White, Knt., alderman of London, in 1557. It consists of a president, fifty fellows and scholars, one chaplain, an organist, six singing-men, six choristers, and two bible-clerks. All the fellows, except six of the founder's kindred, and two from Coventry, two from Bristol, two from Reading, and one from Tunbridge schools, are elected from Merchant Taylors' School, London.

The older buildings of St. John's College are those of St. Bernard's College, founded in the time of Henry VI., by Archbishop Chichele, for scholars of the Cistercian order. King Henry VIII. had granted these premises to Christ Church, Oxford, from which college Sir Thomas White purchased them, under a licence from the crown, in 1555. The second quadrangle of St. John's was entirely built at the expense of Archbishop Laud. It was begun in 1631,

and completed in 1635, from a design furnished by Inigo Jones.

Among the greater benefactors to this College, after the founder, were Dr. John Buckeridge, bishop of Ely, and the Archbishops Laud and Juxon, all of whom were presidents, and the last two successively; Dr. Richard Rawlinson, and Dr. William Holmes, the last of whom was also president from 1728 to 1748, from whom and from whose widow, who followed up her husband's intentions, the College received no less a sum than 15,000*l.*

Among the more eminent members of this College, beside those already mentioned, were Archbishop Tobie Matthew, and Peter Mews, afterwards bishop of Winchester, who were also presidents; Sir William Dawes, afterwards archbishop of York; Campian, the celebrated Jesuit; Sir James Whitelocke; Shirley, the dramatist; Sir Bulstrode Whitelocke; Sir John Marsham, the chronologist; Dr. Edward Bernard; Sherrard and Dillenius, the botanists; and Dr. Tucker, dean of Gloucester.

From the founder's endowment, and by means of other benefactions, this College is possessed of the following livings:—the *rectories* of Aston-le-Wall, Creek, and East Farndon, in Northamptonshire; Baynton in Yorkshire; Bardwell in Suffolk; Barfreston in Kent; Belbroughton in Worcestershire; Cheam in Surrey; Codford St. Mary in Wilts; Handborough and Tackley in Oxfordshire; Kingston Bagpuze in Berks; Sutton in Bedfordshire; Leckford and South Warnborough in Hampshire; Winterburne in Gloucestershire; and Cranham in Essex; the *vicarages* of Chalfont St. Peter in Buckinghamshire; Charlbury and Kirtlington in Oxfordshire; St Giles's in the suburbs of Oxford; Fyfield and St. Lawrence Reading in Berkshire: St. Sepulchre's, London; Linton in Herefordshire; and Stoughton Magna in Huntingdonshire; and the *curacies* of Frenchay in Gloucestershire, and Summer-town Chapel in the suburbs of Oxford.

The present number of members of this College, dependent and independent, is 226, exclusive of the choir.

(Gutch's *Colleges and Halls of Oxford*: Chalmers's *Hist. of the Univ.*; *Oxford Univ Calendar* for 1838.)

JOHN'S COLLEGE, ST., CAMBRIDGE, was projected and begun by Margaret countess of Richmond, a short time before her death, which happened in 1509. It was completed by her executors, under the authority of a papal bull and the royal mandates of her son and grandson King Henry VII. and King Henry VIII., which gave them the power of suppressing a decayed hospital dedicated to St. John, at that time existing on the same site. The College, then consisting only of the present first court, was four years in building: the fabric is said to have cost between four and five thousand pounds. The statutes of the College were given by Henry VIII.; but these having become confused and ambiguous, owing to various changes, erasures, and marginal notes, Queen Elizabeth gave the College a new set of statutes.

The original endowment was for fifty fellows; but part of the foundation-estates having been seized by King Henry VIII., the funds were found to be sufficient for thirty-two only. These fellowships are (by letters patent from Geo. IV. on the petition of the college, and in pursuance of a power to that effect said to be reserved to the crown by the statutes of Henry and Elizabeth) now open to natives of England and Wales, without any restriction or appropriation whatsoever, one only excepted, which is in the appointment of the bishop of Ely; but the bishop is required, agreeably to an arrangement between James Stanley bishop of Ely, and the executors of the countess of Richmond, to elect according to the statutes in every respect.

There are also twenty-one fellowships founded by different benefactors, which have all the privileges of the former, and give an equal claim to the college patronage.

Besides these there are numerous scholarships, exhibitions, &c. belonging to this college: the former amount to no fewer than 114.

The present buildings consist of the first court, a second court of large dimensions, and a third, which contains the library. A handsome new court has recently been built by Rickman on the opposite side of the river Cam, and is connected with the old buildings by a bridge.

This being a divinity college, all the fellows are obliged to take priest's orders within six years from the degree of M.A., except four, who are allowed by the master and seniors to remain laymen; two for the practice of physic, and two for law. The rest must proceed to the degree of B.D. at the regular time. The electors to fellowships are the master and eight senior resident fellows. The visitor is the bishop of Ely. The number of persons on the boards of this college, March 12th, 1838, was 1096. The schools of Pocklington and Sedburgh in Yorkshire, Shrewsbury in Salop, Rivington in Lancashire, Stamford in Lincolnshire, and Aldenham in Herts, are in the patronage of this college: the benefices in the gift of this college are the rectories of Houghton Conquest with Houghton Gildaple, Marston Mortaine, and Mapershall, in Bedfordshire; the vicarages of Aldworth and Sunninghill, in Berks; the rectories of Brinkley and Fulbourn, and the chapel of Horningsea, in Cambridgeshire; the rectory of Aberdaron in Caernarvonshire; those of Morton in Derbyshire and Marwood in Devonshire; of Fratring cum Thorington, Lawford, Morton, Oakley Magna, and Warley Magna, in Essex; the vicarage of Hormead Magna, and the rectories of Hormead Parva and Lilly, in Herts; of Freshwater in Hants: the vicarages of Higham and Ospringe, and the rectories of Murston and Staplehurst, in Kent; the vicarage of Barrow on Soar, and the rectory of Medbourn cum Holt, in Leicestershire; the vicarage of Minting, in Lincolnshire; the rectories of Thurston cum Snoring, Holt, Ditchingham, Fornset, Sterston, South, and Aldburgh, and the vicarage of Cherry Marham, in Norfolk; the rectory of Ufford cum Bainton, in Northamptonshire; the vicarage of North Stoke, and the rectory of Souldern, in Oxfordshire; the rectories of St. Florence, in Pembrokeshire; of Barrow, Cockfield, and Leyham, in Suffolk; of Wootton Rivers, in Wilts; of Brandeston, and Holme including the vicarage of Holme in Spalding Moor, and the vicarage of Marton cum Grafton, in Yorkshire. (Lysons's *Magna Britan.*, 'Cambr.,' and the *Cambr. Univ. Calendar* for 1838.)

JOHN'S, ST. [NEWFOUNDLAND.]

JOHN'S, ST. [NEW BRUNSWICK.]

JOHN'S, ST., RIVER. [MAINE.]

JOHNSON, SAMUEL, the son of Michael Johnson, a bookseller at Lichfield, and Sarah, his wife, was born at Lichfield on the 18th of September, 1709. As a child he was afflicted with the king's evil, which disfigured his face and impaired his eyesight, and he was taken to Queen Anne to be touched. His education was commenced at Lichfield, whence he was removed to a school at Stourbridge; and in 1728, two years after he had left Stourbridge, he was placed at Pembroke College, Oxford. Young Johnson had early shown a vigorous understanding and an eagerness for knowledge: though he had poverty to contend with and a natural indolence, and was also subject to periodical attacks of morbid melancholy, he acquired a large fund of information at the university. Necessity compelled him to abandon the hope of taking a degree; his debts, though small, were increasing; remittances from Lichfield could no longer be supplied; and he quitted college and returned to his father's house. In the December following (1731) his father died in such pecuniary distress, that Johnson was soon afterwards glad to become usher of a school at Market Bosworth, in Leicestershire, to which, it appears from his diary, that he went on foot: 'Julii 16,' he writes, 'Bosvortiam pedes petii.' But finding the drudgery of this employment intolerable, he sought other means of obtaining his bread, and procured temporary employment in translating for a bookseller in Birmingham. During his residence in this town he became intimate with the family of a mercer named Porter, whose widow he subsequently married (1736). Mrs. Porter was more than twenty years older than himself, but he was fondly attached to her, and she added to other powers of increasing his happiness the possession of 800*l.* With this capital he established a school, but his advertisements produced few scholars, the scheme failed, and he left Staffordshire with his pupil Garrick to seek his fortune in the metropolis. His prospects must have been very gloomy: he had nothing but literature to trust to for subsistence, and those were times when the condition of literary men was most miserable and degraded. In the reigns of William, of Anne, and George I., successful writers were rewarded by private munificence and public situations. But such patronage was now at an end; and the year in which Johnson left his home formed part of an interval which elapsed before a new source of remuneration arose—before the number of readers became large. Of readers there were still but few; the prices therefore that booksellers could afford to pay to authors were necessarily

small, and an author, whatever were his talents or his industry, had great difficulty in keeping a shilling in his purse. The poverty and neglected condition of his friend and brother author Savage were the causes of Johnson's writing his 'London,' an imitation of the third satire of Juvenal, for which Mr. Dodsley gave him ten guineas, and by which he obtained a certain degree of reputation. We are told that when Pope read it he said, 'The author, whoever he is, will not be long concealed.' No great advantage however immediately accrued to him. Again he sought to be a schoolmaster, again his scheme miscarried, and he returned to his drudgery in the service of Cave the bookseller, who was his only patron. His pen was continually at work, and his pamphlets, prefaces, epitaphs, essays, and biographical memoirs, were continually published by Cave, either by themselves or in his periodical the 'Gentleman's Magazine.' For many years his bread continued to be earned by literary slavery; by slow degrees only did his great talents become known, and the trust reposed in him by publishers increase. In 1740, and for more than two years afterwards, he wrote the parliamentary speeches in the 'Gentleman's Magazine.' In 1744 he published his 'Life of Savage;' in the following year some observations on Shakspeare, whose plays he proposed to edit; and in 1747 he commenced his 'English Dictionary,' which he engaged to complete in three years for 1575*l.*, a small sum if we consider that the author agreed to bear the heavy expenses necessary for preparing a work of such magnitude and importance. In 1749 appeared 'The Vanity of Human Wishes,' an imitation of the tenth satire of Juvenal; and in the following year was printed the first paper of the 'Rambler.' These are some of his most remarkable publications, for a complete list of which, and the dates at which they were published, we must refer to Boswell's 'Life.' For 'The Vanity of Human Wishes' 15 guineas only were received from Mr. Dodsley. We mention this because the frame and condition of Johnson's mind and temper, his views of things and persons, were influenced in no small degree by the deficiency of his means. He was now engaged in a steady course of occupation sufficient to employ his time for several years; and so assiduous were his labours, that at his residence in Gough Square he had an upper room fitted up like a counting-house, in which several copyists sat, whom he supplied with continual employment. The efforts of his mind were the utmost it could bear; and when it was subdued by grief at the death of his wife (1752), he relinquished the 'Rambler.' Bad as his circumstances were, still they were somewhat more easy than they had been: the number of his acquaintances had increased; the Dictionary, which occupied eight instead of the promised three years, was nearly complete; and he found leisure (in 1754) to make an excursion to Oxford for the purpose of consulting its libraries. This was his first emancipation from necessary labour. He soon returned to London to increase the number of reviews and essays, which flowed continually from his pen. Thus occupied, an offer of a living was made to him if he would take orders: but though he was a firm believer in revelation, and a somewhat rigid moralist, he could not overcome his scruples respecting the fitness of his temper and habits for the duties that would be required of him, and the offer was rejected. He continued therefore to write for his bread; and it was not until he was fifty-three years old, and had for thirty years been toiling with his pen, that any certain source of income was opened to him. In May, 1762, George III., through his minister Lord Bute, granted Johnson a pension of 300*l.* a year, and the days of his penury were at an end. Happy, in a state of independence, he enjoyed the society of a weekly club, of which Burke, Goldsmith, and Sir Joshua Reynolds were also members. He was introduced in the following year to his biographer Boswell, and we have from this date (1763) as full and minute account of him as has ever been written of any individual. From this time we are made as familiar as it is in the power of writing to make us with the character, the habits, and the appearance of Johnson, and the persons and things with which he was connected. 'Everything about him' (says the *Edinburgh Review*, vol. liii., p. 20), 'his coat, his wig, his figure, his face, his scrofula, his St. Vitus's dance, his rolling walk, his blinking eye, the outward signs which too clearly marked the approbation of his dinner, his insatiable appetite for fish-sauce and veal-pie with plums, his inextinguishable thirst for tea, his trick of touching the posts as he walked, his mysterious practice of treasuring up scraps of orange-peel, his morning slumbers, his midnight disputations, his contortions, his mutterings, his gruntings, his puffings; his vigorous, acute, and ready eloquence; his sarcastic wit, his vehemence, his insolence, his fits of tempestuous rage, his queer inmates—old Mr. Levett and blind Mrs. Williams, the cat Hodge, and the negro Frank—all are as familiar to us as the objects by which we have been surrounded from childhood.'

In 1765 the university of Dublin sent over a diploma creating him a doctor of laws, but he did not assume the title of doctor until eight or ten years afterwards, when the university of Oxford conferred the same honour upon him.

In 1766 his constitution seemed to be rapidly giving way, and he was depressed with a deep and gloomy melancholy. In this condition his friend Mr. Thrale received him into his house at Streatham; an apartment was fitted up for him, companions were invited from London, and he became a constant resident in the family. His celebrity attracted the notice of the king, to whom he was introduced by the librarian of Buckingham House. We are not told that politics had in any way led to this introduction, but it is not impossible that the opinions that Johnson entertained upon the principal questions of the day might have reached the king's ears. For several years he occasionally published political pamphlets. In the autumn of 1773 he made a tour, in company with Mr. Boswell, to the Western Islands of Scotland, of which he published an account. Two years afterwards he made a short excursion to Paris. The last of his literary labours was 'The Lives of the Poets,' which were completed in 1781. We now take leave of him as an author, and have only to record the few domestic occurrences which took place before the close of his long life. These are for the most part melancholy. His friends Mr. Thrale and Mrs. Williams preceded him to the grave. In June, 1783, he had a paralytic stroke, and in the following November was greatly swollen with the dropsy. During a journey to Derbyshire he felt a temporary relief; but in 1784 he suffered both from dropsy and from asthma. His diseases were evidently irremediable; the thought of death preyed upon his mind, and the history of his death-bed is painful. On Monday, the 13th of December, 1784, he expired in his house in Bolt-court; on the 20th of the month his remains with due solemnity and a numerous attendance of his friends were buried in Westminster Abbey, near the foot of Shakspeare's monument, and close to the grave of Mr. Garrick.

'The characteristic peculiarity of Johnson's intellect was the union of great powers with low prejudices. If we judged of him by the best parts of his mind we should place him almost as high as he was placed by the idolatry of Boswell; if by the worst parts of his mind, we should place him even below Boswell himself.' (*Edin. Review*, vol. liii., p. 27.)

Though poverty made him a pensioner and a ministerial partisan, he had great independence of character, and his Tory opinions are to be attributed to disinterested conviction, and were in harmony with his general spirit. He was steady and inflexible in maintaining the obligations of religion, a sincere and zealous Christian, and, as such, benevolent. Besides these great qualities he possessed others of a most humiliating littleness. In many respects he seemed a different person at different times. He was intolerant of particular principles, which he would not allow to be discussed within his hearing; of particular nations, and particular individuals. He was superstitious; and his mind was at an early period narrowed upon many questions religious and political. He was often the first to practise what he had censured in others, and this not from a passionate want of control, but from an ignorance of himself. 'He was no master of the great science of human nature; he had studied not the *genus* man, but the *species* Londoner.' He was open to flattery, hard to please, easy to offend, impetuous and irritable. These were the principal blots upon his character, but his great qualities predominated, and he has left more to admire and revere than to censure and condemn.

His reasoning was sound, dextrous, and acute; he was seldom imposed upon either by fallacies or exaggerated statements; his perception was quick; his thoughts striking and original, and his imagination vivid. In conversation his style was keen and pointed, and his language appropriate; he had also a remarkable facility of illustration

from familiar objects. His wit may be described as logical, and chiefly consisted in dextrously convicting his opponent of absurdity. Conscious of his power, he was fond of dispute, and used to argue for victory. Scarcely any of his contemporaries except Burke was a match for him in such discussions. His written style was eminently periodic; and in order to construct every sentence into a balanced period he frequently introduced superfluous and high-sounding expressions; hence his general style was pompous, heavy, bombastic, and diffuse. He was also fond of words of Latin derivation, to the exclusion of more familiar words of Saxon origin. A good burlesque of his style may be seen in the 'Rejected Addresses.'

Johnson's strong and penetrating intellect did not fit him for poetry. His 'Irene' is deservedly forgotten. His 'Imitation of the Third Satire of Juvenal' contains some nervous thoughts expressed in harmonious verse. His 'Imitation of the Tenth Satire of Juvenal' is a fine poetical declamation, though deformed by occasional tautology. Among his smaller pieces the two most remarkable are his verses on the opening of Drury-Lane Theatre in 1747, 1747, and the stanzas on the death of Mr. Levett; the latter of which is, in our opinion, the most poetical of Johnson's productions. His tale of 'Rasselas' holds an intermediate place between his poetry and his prose. It is characterized by a tone of pleasing melancholy, and the style, though somewhat artificial, is elegant and harmonious.

His prose works consist of short pieces, his Dictionary excepted. His 'English Dictionary' was a work of great labour, and the quotations are chosen with so much ingenuity, that, though necessarily mere fragments, they are amusing to read. Dr. Robertson, the historian, said that he had read Johnson's Dictionary from beginning to end. It is however in some respects a very defective work. Johnson had scarcely any knowledge of the Anglo-Saxon, and no knowledge of any of the cognate Teutonic dialects; accordingly the etymological part is not of much value; the etymologies being blindly copied chiefly from Skinner and Junius. His definitions are constructed without sufficient consideration, and without any systematic plan. He also frequently errs in tracing the successive significations of a word. Between 1750 and 1760 he published the 'Rambler' and the 'Idler,' periodical essays in the style of the 'Spectator.' Johnson was as little fitted for this species of composition as for poetry; his serious essays generally consist of trite morality, and his attempts at facetiousness are ponderous and clumsy. His edition of Shakspeare was published in 1765; the preface is one of his ablest productions, particularly that part which relates to the unities and dramatic illusion. He had not sufficient antiquarian knowledge or poetical feeling for commenting on Shakspeare; his notes are not numerous, and though marked with his strong sense are only occasionally valuable. In 1775 he published the account of his journey in the Hebrides, an entertaining and even an instructive work, though it discusses with needless solemnity subjects familiar to every inhabitant of the country, but strange to a townsman like Johnson. His 'Lives of the Poets,' published in 1781, are a useful and interesting contribution to English biography and criticism, and are too well known to require specific notice. The criticisms in this work are sometimes biased by political, religious, and even personal antipathies, as may be seen in his unfavourable judgment of Milton's poetry, dictated by his dislike for the republican and non-conformist; and his captious censure of Gray, which evidently proceeded from his jealousy of a successful contemporary. His judgments of the general character of a poet are however more frequently correct than his criticisms upon particular passages and expressions. His verbal criticisms on poetry are for the most part the mere cavillings of a prosaic grammarian.

A complete list of Johnson's works is prefixed to Boswell's 'Life;' but from what has been stated, it sufficiently appears that his intellectual efforts were desultory and unconnected, and took the form of Essays, Lives, Critical Notices, Prefaces, &c. He had no comprehensive or profound acquaintance with any department of human knowledge; he did not attempt any systematic investigation of any considerable branch of metaphysical, ethical, political, or æsthetical science. Even as a grammarian, his acquirements were shallow and limited; of physical and mathematical science he was quite ignorant. It may however be remarked that he had adopted that theory of ethics which is now commonly known by the name of *utilitarian*, as may be seen from his review of Soame Jenyns's 'Inquiry into the Origin of Evil,' his ablest speculative production. Johnson here says of this theory, that it affords 'a criterion of action on account of virtue and vice, for which he has often contended, and which must be embraced by all who are willing to know why they act or why they forbear, to give any reason of their conduct to themselves or others.'

From his habit of writing for the booksellers, he had acquired a power of treating the most heterogeneous subjects with scarcely any preparatory knowledge; witness his papers on the construction of Blackfriars Bridge, and his argument, dictated to Boswell, on a question of Scotch law. In English literature his reading was extensive, particularly in the writers of the seventeenth and eighteenth centuries; but he seems to have known little about the writers of the age of Elizabeth: his 'Lives of the Poets' begin with Cowley. He had not studied attentively the works of any of the chief English philosophers, as Bacon, Hobbes, Locke; his theological learning was scanty; nor was he well versed in the political history or laws of his country. He had a fair acquaintance with the ordinary Latin classics; of Greek he knew but little. He could read French and Italian; but he seems to have been nearly ignorant of the modern literature of foreign countries.

Johnson's opinions were regarded by many of his contemporaries with a sort of superstitious reverence, and even his style was considered worthy of imitation. In the present generation his credit has perhaps fallen lower than it deserves. Many of his works will long continue to be read, if not for their intrinsic value, at least from the vigour of thought which they display.

(Murphy's *Life*, in preface to Works; Boswell's *Life*, Croker's edit., including two curious vols. of 'Johnsoniana;' *Memoir* by Walter Scott, Prose Works, vol. iii.; *Edin. Review*, vol. liii. A brief but elaborate and able character of Dr. Johnson has been written by Sir James Mackintosh, and will be found in his *Life*, vol. ii., p. 166.)

JOINT. [ARTICULATION.] Everything that need be here said on Joints is contained in the article referred to.

JOINT STOCK COMPANIES [BANK, BANKER, BANKING; PARTNERSHIP.]

JOINT TENANCY signifies joint ownership of two or more persons in land, or other property, as goods and chattels. It differs from Tenancy in Common [COMMON, TENANCY IN] and Coparcenership [PARCENERS] in the following essentials: joint tenants are severally seised or possessed of the undivided whole of the land or other property in which they have a joint interest, and also of their several shares, which shares are always equal shares, inasmuch as joint tenants take by purchase only, and by a joint title: the estate or interest must be limited to the several persons by the same deed or instrument, and such estate or interest must vest in them at the same time, except (according to the more common opinion) the estate be limited to take effect under the Statute of Uses or by devise, in which cases the contemporaneous vesting of the several parts is not necessary: the whole estate or property will go to the survivors and survivor of the joint tenants, if the jointure continue until such survivorship; which is the important characteristic of a joint tenancy. It is a consequence of the mode in which joint tenants are legally considered to be seised or possessed, and of the right to the whole which accrues to the survivors and survivor, if no separation of the joint tenancy has been made before such survivorship takes place—that they cannot grant, or bargain and sell, or surrender or devise to each other; they cannot exchange with each other, nor can one make a feoffment to another. But any joint tenant may transfer his interest to any one of his companions by release, or rather he can by such instrument put an end to his interest; and any joint tenant may convey his share to a stranger by grant; or he may compel his companions to make a partition, by statute. Every person to whom the interest of a joint tenant is transferred becomes, as to such share, a tenant in common with the remaining joint tenants.

A joint tenant cannot dispose of either the whole or the part of the property in which he is jointly interested consistently with the proper notion of a joint tenancy, by a will made during the continuance of the joint tenancy, even though he should happen to be the survivor; because until he has survived he has nothing to dispose of by will. But by severing the joint tenancy he acquires the power of disposing of his share by will. By a recent act (1 Vict., c. 26), a person may by a will, made according to the provi-

sions of that act, dispose of all real and personal estate to which he shall have a legal or equitable title at the time of his death, and which, if not disposed of by will, would go to his heir, or the heir of his ancestor, or to his personal representatives. But this act gives no power of disposal over the unsevered interest of a joint tenant.

As to the written instruments and words by which a joint tenancy may be created, and the various rights and remedies which belong to a joint tenant, it is not necessary to dwell at any length here. The discussion of them belongs to special treatises on law. As an example of words which would create a joint tenancy, we may take the case of a feoffment to two or more persons and their heirs, which would make the feoffees joint tenants in fee simple, so that the survivors would always succeed, and the last survivor would take the whole in fee, unless any one of the joint tenants had in his lifetime conveyed his share. And generally, when there is a gift of real or personal estate to several persons, and nothing more is said, these words make them joint tenants, even in the case of pecuniary legacies and residuary bequests. To create a tenancy in common, it is not necessary, either in a deed or will, to declare that the parties to whom the gift or devise is made shall take it as tenants in common, and not as joint tenants. Any words which undoubtedly convey this meaning are sufficient for the purpose; but less exact or definite words are required for this purpose in a will than in a deed. Where an estate is given to two persons and the heirs of their bodies, if the two persons are such as cannot have common heirs of their bodies (as two men or two women, or a man and a woman who cannot legally intermarry), then such persons are joint tenants for life, but have separate inheritances, or are tenants in common in remainder in tail. But if the gift be to a man and his wife and the heirs of their bodies, or to a man and woman who may marry and the heirs of their bodies, the parties are joint tenants of the inheritance; and if they be husband and wife they take by intireties. The tenancy by intireties is a consequence of the legal unity of husband and wife. Such tenancy exists when real estate is limited by deed or will to husband and wife jointly during their marriage for an estate of inheritance or freehold: the husband and wife possess the lands intirely as one individual; on the death of either of them they go to the survivor, and there is no power of alienation or forfeiture of either alone which can prejudice the right of the other.

Partners in trade are joint tenants of the partnership stock which is of a moveable kind, but on the death of a partner his personal representatives become tenants in common in equity, with the surviving partners; and it was at one time considered that they acquired a legal tenancy in common, with the survivor. In equity there is no survivorship in lands which partners have held for the purposes of trade.

If money is jointly advanced by two or more persons on a mortgage security, there is in equity no benefit of survivorship among them.

A joint tenant, like a tenant in common, cannot maintain an action of trover against his companion for goods which are in his companion's possession; for according to the English doctrine of possession, possession by one joint tenant, tenant in common, or parcener, is generally the possession of all. The doctrine of possession by joint tenants, tenants in common, and parceners, is materially altered as to lands and rents by 3 and 4 Will. IV., c. 27, sec. 12, and in another case by sec. 13.

JOINTURE. This legal term was originally used to denote the interest of joint tenants, which interest was called an estate *in jointure*. Before the statute of 27 Henry VIII., c. 10 (of Uses), lands conveyed to uses were not subject to dower; and as such conveyances were frequent, it became usual to stipulate, upon a treaty for a marriage, that the intended husband should convey an adequate portion of his lands to the use of himself and wife *in jointure*, i.e. as joint tenants for their lives, whereby a provision would be secured to the wife, if she survived, commensurate in point of duration with the dower which the common law would have given her, if the system of uses had remained unknown. When the Statute of Uses was passed for transferring the legal estate to the *cestui que use*, it was considered unreasonable that wives should by means of the destruction of uses be entitled to claim dower in their husbands' lands, and should at the same time enjoy a provision made for them in consideration that they were not so entitled. The sixth section of this statute therefore provided that women having provisions in the nature of jointures should not be entitled to claim dower of the residue of their husbands' lands. [DOWER.]

An estate limited to a woman must, in order to be deemed a good jointure and a bar to dower under this statute, commence and take effect in possession or in profit immediately on the death of the husband. It must also be for the life of the wife, or for some greater estate. It must be in satisfaction of the whole dower, and not of a part only. It must be made before the marriage; for by the ninth section, if the jointure be made during the marriage, the wife is at liberty after the death of her husband to refuse the jointure and demand her dower. If however the widow once accept such jointure, she is perpetually bound, even though the estate in jointure created during the marriage be made subject to a condition, and is in that respect less beneficial than dower.

A woman, though under age at the time of her marriage, is bound by an antenuptial jointure, inasmuch as the bar of dower arising out of the limitation of a jointure is not a matter of contract (by which minors are not bound), but proceeds upon the ground of the substitution of a new provision made by the husband, or on his behalf, under the authority of an act of parliament. It was formerly considered that the estate must be directly limited to the wife herself, and not conveyed to others in trust for her; but it is now settled that a trust estate is a good equitable jointure in bar of dower.

Where an estate tail is limited to a woman for her jointure, she is restricted from alienation or discontinuance by 11 Henry VII., c. 20, and 32 Henry VIII., c. 36; on the other hand, if she be lawfully evicted from the whole or part of the jointure lands, she will be entitled to be endowed of the residue of the lands of which, but for such jointure, she would have been dowable, to the value of the lands of which she has been deprived by such eviction.

In consequence of the practical inconveniences attending a limitation of land by way of jointure, it has become usual to create a rent-charge (*i.e.* an annuity charged upon land with a power of distress) for the life of the wife, with the power of distress, and also a power of entry, that is, the right of entering upon the land charged and retaining the possession until the annuity is paid, and further protected by a demise of the land to a trustee for a term of years. Such annuity ought in strictness to be charged upon the land which would otherwise be liable to dower, or upon some part of it.

This arrangement is equally beneficial to the widow and to the heir or devisee of the husband. A more certain income is provided for the widow, and the heir or devisee may enter into the immediate possession and take upon himself the management of the whole estate. This substituted provision by way of annuity is frequently called the wife's jointure. (*Co.-Litt.* and Hargrave's *Notes;* Cruise's *Dig.;* Bacon's *Abr.*)

JOINVILLE, JEAN, SIRE or LORD DE, born of a noble family of Champagne, was brought up in the court of Thibaut, king of Navarre and count of Champagne, then one of the most polished courts in Europe. Joinville followed Louis IX. in his first crusade in 1248 with a body of several hundred armed men, which he raised among his tenants; and he was present at the taking of Damiata, and at the disastrous campaign of Massoura, in which Louis and most of his army, with Joinville among the rest, were taken prisoners. Joinville narrowly escaped being killed by the Egyptians; but the ransom being paid, he followed the king to Acre, and was present at the war which was carried on in Palestine, until he returned to France with Louis in 1254. Being a great favourite with the king, and almost constantly near his person during the six years of that crusade, his narrative of that period, written in a simple unpretending style, is extremely interesting. It is entitled 'Histoire de St. Louis, IX. du nom, Roi de France, par Jehan Sire de Joinville,' and has been often republished. One of the best editions is that by Ducange, fol., 1668, with useful notes and learned dissertations. It has been translated into English by T. Jones, 2 vols. 4to., 1807. The character of Joinville, a favourable specimen of a feudal lord in that, the golden age of chivalry, valiant, gay, witty, generous, shrewd, and yet at times careless through vivacity of temper, somewhat worldly and proud of his rank, but withal good-natured and sociable, forms a happy contrast with the piety, auste-

rity, and simplicity of Louis, who however esteemed and loved Joinville for his sincerity and abilities, as much as Joinville cherished Louis's honesty and goodness of heart, of which he gives numerous and affecting proofs in his narrative. Joinville, after his return to his native domain, did not forsake the king, but frequently repaired to his court, and continued to enjoy Louis's confidence. When Louis, in 1269, set out on his second expedition, in which he died at Tunis, he invited Joinville to join him, but he excused himself. Joinville kept away from the corrupt court of Philip le Bel, but afterwards he is said to have joined the army which Louis X. collected at Arras against the Flemish. He died not long after; but the precise epoch of his death is not known. Joinville and his predecessor Villehardouin are among the oldest of the French chroniclers who wrote in the vernacular tongue.

JOLIBA. [Quorra.]

JOMELLI, NICOLO, one of the few celebrated composers of the early part of the last century, whose works justify the encomiums bestowed on them, was born in 1714, at Aversa, according to Mattei—at Avellino, says Burney—both places being near Naples. He was initiated in music by the Canon Muzzillo, and afterwards studied at one of the Neapolitan conservatories, first under Feo, then as the pupil of Leo, confessing himself chiefly indebted to the latter for having inspired him with a true feeling for the art. Subsequently however, when he turned his attention to sacred music, he derived considerable improvement in the more elaborate branches of composition by his intercourse with the learned Padre Martini.

Jomelli produced his first opera at Naples, being then only twenty-three years of age, and so speedily acquired fame, that in 1740 he was summoned to Rome, where he composed two operas, and was warmly patronized by the Cardinal Duke of York. Next year he proceeded to Bologna, and brought out his 'Ezio.' He then returned to the papal capital, and produced one of his finest works, 'Didone.' This led to his being invited to Venice, at that time the great theatre for the display of musical excellence, where his 'Merope' for the *Teatro Fenice*, and a 'Laudate' for the church of Santo Marco, well sustained his reputation. The failure of his 'Armida,' in the following year, at Rome, determined him to visit Germany, and at Vienna he formed an acquaintance with Metastasio, which ripened into a friendship of the closest kind, that death only terminated. To the enlightened conversation and judicious criticisms of the Imperial poet he always confessed his obligations, and to which he ascribed much of the success of his later productions. He set the 'Achille in Sciro,' and got up afresh the 'Didone,' of his illustrious friend, both of which were received by the Germans with enthusiasm.

Metastasio, speaking of Jomelli, in several letters, says, 'He is of a spherical figure, pacific disposition, with an engaging countenance, most pleasing manners, and excellent morals. . . . . He is the best composer for words of whom I have any knowledge. . . . . If ever you should see him, you will be attached to him; he is certainly the most amiable *gourmand* that ever existed.'

At Vienna Jomelli remained two years, where he devoted no inconsiderable portion of his time to the beautiful and accomplished empress Maria Theresa, to whom he gave instructions in music. He was afterwards recalled to Rome, and there produced several operas, also his famous oratorio 'La Passione.' The duke of Würtemberg now prevailed on him to visit Stuttgard, in which city he resided nearly twenty years, and composed an incredible number of Italian operas, most of them however now forgotten; but his 'Missa pro Defunctis,' or 'Requiem,' there produced, will always be known and remain as a monument of his genius. When the duke of Würtemberg was obliged to reduce his establishment, Jomelli went to Naples, where the ill success of two new operas operated so powerfully on his sensitive mind, that an attack of paralysis was the consequence. From this however he sufficiently recovered to compose a Cantata and a 'Miserere,' the latter being by many considered the finest of his works. He died at Naples, in 1774.

Jomelli has been not unaptly called the 'Glück of Italy.' He possessed the deep feeling and vigour that characterized the German composer, and is nearly as rich in accompaniments. Indeed in his admirable, his marvellously affecting scena, 'Berenice, ove sei?' in the serious opera of 'Lucio Vero,' he not only left at an unmeasurable distance all former and contemporary composers, but gave birth to a work which has never yet been surpassed, if ever equalled, and which must transmit his name to posterity, so long as a taste for what very nearly approaches the sublime in music shall exist. We hardly need mention his 'Chaconne,' it is familiar to all; and though not of so high an order of composition as some of the above-named works, yet its great and long-continued popularity is an incontestable proof of its originality and other sterling merits.

JONAH (יוֹנָה, Ἰωνᾶς), was one of the twelve minor Hebrew prophets. He is mentioned in 2 *Kings*, xiv. 25, where we are told that Jeroboam II. 'restored the coast of Israel from the entering of Hamath unto the Sea of the plain, according to the word of the Lord God of Israel, which he spake by the hand of his servant Jonah, the son of Amittai, the prophet, which was of Gath-hepher,' or Gittah-hepher (*Joshua*, xix. 13), a city near the eastern boundary of the tribe of Zebulun, which formed a part of the kingdom of Israel, and afterwards of Galilee. From this passage most critics have supposed that Jonah lived under Jeroboam II., who reigned from 823 to 782 B.C. Bishop Lloyd places him near the close of Jehu's reign, or the beginning of that of Jehoahaz. The book of Jonah, with the exception of the highly poetical prayer in chap. iii., is entirely narrative. It may be divided into two parts. The first (chaps. i. and ii.) relates the attempt of Jonah to evade God's command to preach to the people of Nineveh by fleeing to Joppa, and there embarking in a ship sailing for Tarshish; his being thrown into the sea and swallowed by a fish, in the belly of which he remained three days and three nights; and his deliverance from the fish, which at the command of the Lord vomited him out upon the dry land. The second part gives an account of his second commission to Nineveh, where the king and people repented at his preaching (chap. iii.); his anger because God, upon the people's repentance, did not execute the judgments which the prophet had predicted, and the striking reproof which Jonah received (chap. iv.). The history of Jonah is referred to in several passages of the New Testament (*Matt.* xii. 39-41; xvi. 4; *Luke*, xi. 29, 30, 32), from which it appears improbable that the book of Jonah is to be considered merely a parabolic story, as some have supposed. The canonical authority of the book is generally admitted.

Bochart supposes that the fish which swallowed Jonah was a species of shark (Bocharti *Opera*, tom. iii., p. 742), and Townsend endeavours to identify it with the idol-fish worshipped at Ascalon under the name Derceto.

(The *Introductions* of Horne and Jahn; Calmet's *Dictionary*; Townsend's *Old Testament arranged in Chronological Order*; Rosenmüller's *Scholia*; and list of commentators in Watt's *Bibliotheca Britannica*.)

JONATHAN APPHUS was the youngest brother of Judas Maccabæus, on whose death he was chosen commander of the Jewish forces. After carrying on the war with some success for a few years, he made peace with Bacchides, the general of Demetrius Soter. At the commencement of Alexander's insurrection [Alexander Balas], Jonathan's alliance was warmly courted both by Demetrius and by Alexander. He joined the latter, by whom he was appointed high-priest (B.C. 153). He continued in great favour with Alexander during that king's life, and defeated Apollonius, the governor of Cœle-Syria, who had espoused the cause of Demetrius Nicator. He also laid siege to the Syrian garrison in the castle on Mount Zion. On the accession of Demetrius Nicator, Jonathan succeeded in obtaining the confirmation of his power; but, disgusted by the faithless treatment he afterwards received from Demetrius, he joined the insurrection of Trypho in favour of Antiochus Theos, whose cause he supported with great success. He also confirmed the alliance made by Judas with the Romans. Trypho had put Antiochus on the throne with the purpose of afterwards usurping it himself. Dreading the powerful opposition of Jonathan, he took him by treachery and put him to death, in B.C. 144.

(1 *Maccabees*, chaps. ix.-xii.; Josephus, *Antiquities of the Jews*, book xiii., chaps. i.-vi; Jahn's *Hebrew Commonwealth*, vol. i.)

JONES, INIGO, who has been styled the English Palladio, and who forms an epoch in the history of architecture in this country, was born in the neighbourhood of St. Paul's in London, where his father was a respectable cloth-

worker. Of his youth and education very little is known,—perhaps quite as much as was to be known,—except that by his talent for drawing he attracted the notice of William earl of Pembroke, by whom he was sent abroad, where he spent three or four years studying with his pencil, measuring and examining various remains of antiquity, as well as modern buildings. At that period such task required much greater application and diligence than at present, when almost every ancient building has been shown in engravings, and when the student has been previously familiarised at home with specimens of almost every style, including those of edifices avowedly Italian in their design. Jones, on the contrary, found himself in an entirely new world of art, for the ancient orders were then utterly unknown in England, nor were the Italian orders known, except as exhibited in diminutive columns, pilasters, entablatures, and pediments, applied merely as adscititious ornaments patched upon a degenerate Tudor style. So far the times were eminently propitious to Jones, nothing more being required than for him to transplant the full-grown Italian style, as he found it in the works of Palladio and that school, in order at once to obtain the celebrity of an originator. It was not however until many years after his first visit to Italy that he fully adopted the 'classic' taste.

About the year 1604 he was invited from Italy to Denmark by Christian IV., for whom he is said to have designed part of the buildings of the royal château of Frederiksborg, and also the palace of Rosenborg. Fortunately this is doubtful, there being nothing in the architecture of either of these that would reflect any credit on the taste of our English Palladio. Yet, whether the patronage of the Danish monarch did much for Jones or not, in itself, it promoted his interest at the English court, Christian's sister being the queen of James I. Inigo returned to England in 1605, and was immediately employed at court in devising the machinery and decorations of the costly masques and pageants then in vogue. He was appointed architect to the queen and to Prince Henry. None of his best works belong to this period, for it was not till after his second return from Italy, which he again visited in 1612, on the death of the prince, that he emancipated himself from the mesquin style that had succeeded the downfal of Tudor architecture. Without this second residence in Italy he might have designed a palace for Whitehall quite as extensive as the one he actually made, but it would, no doubt, have been very different in style. On his return he was appointed to the surveyorship-general of the royal buildings, and commenced his plans for that just mentioned. Soon after the only portion ever built of it, namely, the Banqueting House, was completed, he engaged in a task of a very different nature, that of ascertaining the origin and purpose of Stonehenge; and notwithstanding that its rude amorphous blocks—from which no lessons were to be derived, even in regard to construction—could have no attractions for the eye of a votary of Vitruvius and Palladio, and little to captivate the fancy of him who had displayed his invention in courtly pageants, he appears to have prosecuted his ungrateful researches with application that deserved a far better object. His fancy however enabled him to see much in those barbaric remains that had never existed; but as for the question, he left it, as he found it, a subject for speculation.

After the building at Whitehall, he was engaged upon the back-front of old Somerset House, and in adding a Corinthian portico to the west front of old St. Paul's. Both of them have been greatly extolled, more especially the latter, but neither of them remains; we have however another very celebrated production of Inigo's in the church of St. Paul, Covent Garden, in regard to which Quatremère de Quincy, though by no means unfavourable to him, says the most remarkable thing about it is the reputation it enjoys. York Stairs, Ashburnham House, Westminster, a house originally built for the Earl of Lindesay, on the west side of Lincoln's Inn Fields, and Surgeon's Hall, yet remain among his works in the metropolis; and when we say that the last-mentioned has been asserted by some to have been one of his best, no very flattering notion is conveyed of the taste of his admirers. In fact the Banqueting House is almost the only specimen that accounts for his reputation, and even that we suspect is now more praised as a matter of course, than really admired. The designs for the palace of Whitehall, together with many others by Jones, were published in a folio volume by Kent. To give a list of all the buildings attributed to him, or even of the principal ones in addition to those mentioned, would occupy a considerable space. He died in June, 1653, at the age of eighty.

JONES, SIR WILLIAM, was born in London, September the 28th, 1746. William Jones, his father, who was a mathematician of some eminence, was born in 1680, and died in 1749. He was the author of 'A New Compendium of Navigation,' 8vo., London, 1702; 'Synopsis Palmariorum Matheseos, or a New Introduction to the Mathematics,' 8vo., London, 1706; 'Analysis per Quantitatum Series, Fluxiones, ac Differentias,' &c., 4to., London, 1711; besides some papers in the 'Philosophical Transactions.'

William Jones having died when his son was only three years of age, the care of the child's education devolved upon his mother, who appears to have been a sensible and intelligent woman. Jones was remarkable in his early years for his progress in learning. At the age of seven he was sent to the grammar-school at Harrow, and though his classical studies were suspended for a twelvemonth when he was nine years old, in consequence of an accident which kept him from the school, he surpassed almost all his schoolfellows in learning; and so high an opinion had Dr. Thackeray, at that time head-master of the school, formed of the talents of his pupil, that he used to say that 'if Jones were left naked and friendless on Salisbury Plain, he would nevertheless find the road to fame and riches.' Dr. Thackeray was succeeded by Dr. Sumner, who had an equally high opinion of the abilities of Jones; he has been known to declare 'that Jones knew more Greek than himself, and was a greater proficient in the idiom of that language.' During the last two years of his residence at Harrow Jones did not confine himself to the study of the classical writers; he learned the Arabic characters, and made some progress in Hebrew. He devoted a considerable part of his time to composition in Latin, Greek, and English; some of his juvenile pieces have been printed in the fragment of a work which he began at school, and entitled 'Limon,' in imitation of a lost work of Cicero. During the vacations he studied the French and Italian languages.

In 1764, at the age of seventeen, he entered at University College, Oxford, where he continued to prosecute his studies with the greatest diligence. He especially directed his attention to the study of Arabic and Persian; and employed his vacations in reading the best authors in Italian, Spanish, and Portuguese. In 1765 he left Oxford, and went to reside in the family of Earl Spencer in order to superintend the education of Lord Althorp. In 1770 he resigned this situation with the intention of going to the bar, but he did not immediately commence his legal studies. During the five years that he resided in Earl Spencer's family he made great acquirements in Oriental literature, and obtained by his publications the reputation of being one of the first Oriental scholars of his age. In 1768 he was requested by the king of Denmark to translate the 'Life of Nadir Shah' from the Persian into French; this translation was published in 1770, with a treatise on Oriental poetry, also written in French, in which he has translated several of the Odes of Hafiz into French verse. In the following year he published a grammar of the Persian language, which is the best grammar of that language that has yet appeared. It has been republished of late years with many additions and improvements by Professor Lee, of Cambridge. In his twenty-first year he began his 'Commentaries on Asiatic Poetry' in imitation of Bishop Lowth's 'Prelections on the Sacred Poetry of the Hebrews.' This work, which was written in Latin, and was published in 1774 under the title of 'Poeseos Asiaticæ Commentariorum Libri Sex,' contains many excellent remarks on Oriental poetry in general and translations from the most celebrated Hebrew, Arabic, Persian, and Turkish poets. It was republished by Eichhorn, at Leipzig, 1776. He also began, during his residence with Earl Spencer, a Dictionary of the Persian language, in which the principal words were illustrated by quotations from the most celebrated Persian authors. In 1771 he replied anonymously in French to Anquetil du Perron, who had attacked the University of Oxford and some of its learned members in his introduction to the 'Zend-Avesta.' This reply was written in such good French that Biorn Sthal, a Swedish Orientalist, says, 'that he had known many Frenchmen so far mistaken in the writer as to ascribe it to some *bel-esprit* of Paris.' For some further remarks on this subject the reader may consult the article ANQUETIL. In 1772 Mr. Jones published a small volume of poems

consisting chiefly of translations from the Asiatic languages.

In 1774 Mr. Jones was called to the bar. Feeling the importance of devoting his whole time to his legal studies, he left all his Oriental books and MSS. at Oxford, and diligently attended the courts of common law. During this time he wrote an essay on the law of bailments, which has since been re-published. The work is characterized by Jones's usual perspicuity and ease of expression; so far as concerns the arrangement and matter, we are not aware that it contains anything original, and it is sufficient to read it to be convinced that the author had not a mind adapted to seize with precision the fundamental principles which form the science of law. Jones's extravagant panegyric on Blackstone is sufficient to show in what manner he had studied law.

In 1780 he became a candidate to represent the University of Oxford in parliament, but finding that he had no hope of success in consequence of his opposition to the ministers of the day, and his condemnation of the American war, he withdrew from the contest. His opinions on political subjects are given in his 'Enquiry into the Legal Mode of Suppressing Riots,' in his 'Speech to the Assembled Inhabitants of Middlesex,' &c., in his 'Plan of a National Defence,' and in his 'Principles of Government;' which are printed in the eighth volume of his works (8vo. edition). After an interval of six years, when he had acquired great reputation in his profession, he again resumed his Oriental studies, and employed the leisure hours of the winter of 1780-1 in translating some antient poems of the highest repute in Arabia, which are called *Moallakat*, or 'suspended,' because they are hung up in the Temple of Mecca. In 1783 he was appointed, through the influence of Lord Ashburton, a judge in the supreme court of judicature at Fort William in Bengal; on which occasion he was knighted. A few weeks after he married Miss Shipley, the eldest daughter of the bishop of St. Asaph.

Sir William Jones arrived at Calcutta at the close of the year; and from this time to that of his death, a period of eleven years, he devoted all his leisure time to the study of Oriental literature. Almost immediately after his arrival he induced those persons who had paid attention to Oriental literature to unite in forming a Society 'for inquiring into the history and antiquities, the arts, sciences, and literature of Asia.' To the 'Asiatic Researches,' which were published by this Society, of which Sir William Jones was the first president, Oriental scholars in Europe are indebted for much of their knowledge of the literature and antiquities of the Hindus. Sir William Jones contributed the following treatises to the first four volumes of the 'Asiatic Researches:' eleven 'Anniversary Discourses' on the different nations of Asia, &c.; 'A Dissertation on the Orthography of Asiatic Words in Roman Letters;' 'On the Gods of Greece, Italy, and India;' 'On the Chronology of the Hindus;' 'On the Antiquity of the Indian Zodiac;' 'On the Second Classical Book of the Chinese;' 'On the Musical Modes of the Hindus;' 'On the Mystical Poetry of the Persians and Hindus,' containing a translation of the Gîtagovinda by Jayadêva; 'On the Indian Game of Chess;' 'The Design of a Treatise on the Plants of India;' and many other treatises of less importance.

The study of Sanskrit principally engaged the attention of Sir William Jones during the first three or four years of his residence in Bengal. When he had attained sufficient proficiency in this language he proposed to the government to publish a copious digest of Hindu and Mohammedan law; he offered to superintend the compilation, and to translate it. This offer was willingly accepted, and Sir William Jones laboured for many years on the work. It was unfinished at the time of his death; but has since been completed under the superintendence of Mr. Colebrooke. The laws of Manu, on which the whole system of Hindu jurisprudence is founded, were translated by Sir William Jones, and published separately in 1794. Those who are interested in Hindu literature are also indebted to Sir William Jones for a translation of Sacontalâ, a dramatic poem by Câlidâsa, which appeared for the first time at Calcutta in 1789; and also for a translation of the Hitopadêsa, which appears to have been the original of the celebrated collection of Persian fables known under the name of Pilpay or Bidpai. [BIDPAI.] But while he was indefatigable in the pursuit of literature, he never neglected his duties as a judge; and 'the inflexible integrity,' remarks Lord Teignmouth, 'with which he discharged the solemn duty of this station, will long be remembered in Calcutta, both by Europeans and natives.' He died at Calcutta, on the 27th of April, 1794, after a few days' illness.

A mere catalogue of the writings of Sir William Jones would show the extent and variety of his knowledge. He had a wonderful facility for the acquisition of languages; his knowledge of Latin and Greek was extensive, though not profound; his acquaintance with Arabic, Persian, and Sanskrit has seldom been equalled, and scarcely, if ever, surpassed by any European; he was familiar with Turkish and Hebrew; and had learned enough of the Chinese to enable him to translate an ode of Confucius. He was also well acquainted with most of the modern languages of Europe,—French, Italian, Spanish, Portuguese, and German; and had studied less critically numerous other languages. His knowledge of science was not so extensive or accurate: he had however made some progress in mathematics; was well acquainted with chemistry; and had studied botany during the latter years of his life with the greatest diligence. But though the attainments of Sir William Jones were so various and extensive, he does not appear to have possessed any originality. He neither discovered new truths nor placed old ones in a new light. He possessed neither the power of analyzing nor of combining and constructing. For language, as a science, he did nothing: he only collected materials for others. His writings on Oriental literature are interesting and instructive; but neither they nor any of his other works are distinguished by any originality of thought or power of expression; his style is weak, and his judgment frequently defective. His literary attainments were certainly such as few men, perhaps none, have ever made; yet with every disposition to admire and honour him for what he has done, we cannot assign him a high intellectual rank. Doubtless he weakened his powers by diffusing them over so large a surface, instead of concentrating them on a few objects. His personal character must always command our respect; he was an indefatigable scholar, an affectionate son, a faithful friend, a useful citizen, and an upright judge.

In addition to the works which have been already mentioned, Sir William Jones published a translation of Isæus; and also translations of two Mohammedan law tracts 'On the Law of Inheritance, and of Succession to Property of Intestates;' 'Tales and Fables by Nizami;' 'Two Hymns to Pracriti;' and 'Extracts from the Vedas.'

A complete edition of the works of Sir William Jones was published in 6 volumes, 4to., 1799, and in 13 volumes, 8vo., 1807, with his life by Lord Teignmouth.

JONES, JOHN PAUL, was born 6th July, 1747, according to the 'Encyclopædia Americana' at Arbingland (Arbigland?), according to other accounts in the parish of Kirkbean, in Kirkcudbright, Scotland. The name of his father, who was a gardener, was Paul; the addition of Jones was assumed by the son after he grew up in life. He went to sea at the age of twelve, and after making many voyages to America and other parts, was in 1768 made captain and supercargo of a vessel which he had shortly before brought safe into port, having, at the request of those on board, when he was sailing in her as a passenger, taken the command on the death of the captain and mate. Having in a few years made a good deal of money, he settled in Virginia in 1773, on a property which fell to him by the death of an elder brother, who had been for some years established there as a planter. After the declaration of their independence by the colonies, he offered his services in the war against his native country, in which he soon greatly distinguished himself. On being appointed to the command of the Providence, he cruised among the West India Islands, and, as it is stated, made sixteen prizes in little more than six weeks. In May, 1777, he proceeded, by order of the Congress, to France, where he was immediately appointed, by Franklin and his brother commissioners, to the command of the Ranger, in which the next year he sailed upon a cruise to the coasts of Britain, and, after making a descent by night at Whitehaven, where he spiked the guns of the forts and set fire to one or two vessels, besides plundering the house of the earl of Selkirk on the opposite coast of Scotland, returned to Brest with 200 prisoners, and the boast that he had for some time kept the north-western coast of England and southern coast of Scotland in a state of alarm with his single ship. In the autumn of 1779 he set sail again on a similar expedition

for the eastern coasts of England and Scotland, in which his success and the terror he created were still greater than on the former occasion. Among other exploits, having encountered the Baltic fleet, he attacked its convoys, the Serapis frigate and the Countess of Scarborough, off Flamborough Head, on the 23rd of September, and, after a sanguinary engagement, succeeded in capturing the first-mentioned of these vessels. For this achievement he was, on his return to Paris, presented by Louis XVI. with a richly ornamented sword, bearing a flattering inscription, was invested with the military order of Merit, and received in every way the most distinguished reception both from the government, the court, and in general society. At this time it seems he wrote verses, and evinced a violent ambition to make a figure in the fashionable world; he is described by an English lady then resident at Paris as 'a smart little man of thirty-six, who speaks but little French, and appears to be an extraordinary genius—a poet as well as a hero.' On his return to America, in February, 1781, a gold medal was voted to him by Congress. He then served till the peace under the French admiral D'Estaing, after which he proceeded to Paris with the appointment of agent for prize-money. Some years afterwards he entered the Russian service with the rank of rear-admiral; but disputes in which he became involved with the Russian naval authorities soon compelled him to retire, on which he returned once more to Paris, where he lived till his death, 18th July, 1792, having, according to his American biographer, gradually sunk into poverty and neglect before he was attacked by disease. 'Jones,' concludes the writer in the 'Encyclopædia Americana,' was a man of signal talent and courage; he conducted all his operations with the most daring boldness combined with the keenest sagacity in calculating the chances of success and the consequences of defeat. He was however of an irritable impetuous disposition, which rendered him impatient of the authority of his superiors, while he was at the same time harsh in the exercise of his own; and he was deficient in that modesty which adorns great qualities and distinguished actions, while it disarms envy and conciliates jealousy. His early education was of a very limited kind. It terminated when he went to sea at the age of twelve; but he supplied its defects by subsequent study, so as to enable himself to write with fluency, strength, and clearness, and to sustain his part respectably in the polished society into which he was thrown. . . . . His memorials, correspondence, &c., are quite voluminous.' A biographical memoir of Jones, by Mr. J. S. Sherburne, appeared, it seems, at Washington in 1825. We may add that in Scotland his name, and the impression of the dread he occasioned, are still alive in the popular memory, and universally familiar to old and young. Some account of his traditionary reputation may be found in a singular book entitled 'The Scottish Gallovidian Encyclopædia,' by John Mactaggart, 8vo., London, 1824 (pp 373-376). According to this writer, who tells us that he has had his information about Jones 'from the lips of many who personally knew him, and all about his singular ways,' he was 'a short thick little fellow, about five feet eight in height, of a dark swarthy complexion.' 'He was,' continues the account, 'a common sailor for several years out of the port of Kirkcudbright, and was allowed to be unmatched on that coast for skill in sea matters.'

JONE'SIA, a genus of plants of the tribe Cassieæ, and of the natural family of Leguminosæ, which was named by Dr. Roxburgh in honour of Sir William Jones, who, in the midst of his numerous other avocations, found time to pay attention to Indian plants. The species are few in number, and indigenous in the islands of the Malayan Archipelago, as well as on the eastern frontier of Bengal, that is, in Silhet and lower Asam. They form trees which are highly ornamental from their handsome, shining, abruptly pinnate leaves, and from the showy nature of their crowded racemes of flowers. *J. Asoca*, the best known species, is often referred to by Hindu poets by the name which has been adopted by botanists to distinguish it as a species. Dr. Roxburgh says, and we can in a great measure coincide with him in opinion, 'When this tree is in full blossom, I do not think the whole vegetable kingdom affords a more beautiful object.' (*Fl. Ind.*, ii., p. 220.)

JONSON, BENJAMIN, was born at Westminster in the year 1574, and educated at Westminster school. While he was there his mother married a second husband, by trade a bricklayer, and when Jonson became of sufficient age to be employed, he worked at his father-in-law's business. According to Dr. Fuller, he soon left it and went to the University of Cambridge, but was obliged from necessitous circumstances speedily to return, and was employed in the new structure of Lincoln's Inn. According to Mr Wood, some gentlemen who saw him working with his father took compassion on him, and he was sent by Camden to Sir Walter Raleigh, whose son he attended on his travels on the Continent. On his return he went to Cambridge. According to a third account, before going to Cambridge he served as a soldier in the Low Countries, and the statement seems to be confirmed by one of his own epigrams. The fact is, that the early part of his life is quite uncertain, though it is well known that on leaving Cambridge he betook himself to the stage, where he proved but an indifferent actor and at first an indifferent author. While a retainer to the stage he had the misfortune to kill a man in a duel, and was committed to prison, where the visits of a Catholic priest converted him to the Church of Rome. Twelve years afterwards he returned to the Church of England.

It was in the year 1598 that his fame rose by the production of the comedy of 'Every Man in his Humour,' at the Globe Theatre, and from this time he adopted the practice of writing a play a year, for several successive years. 'Every Man out of his Humour' was acted at the Globe; 'Cynthia's Revels,' which the author has called not a comedy, but a comical satire, was performed by the children of Queen Elizabeth's chapel, as was also another comical satire, 'The Poetaster.' This last piece was occasioned by a quarrel with Decker, who is satirized under the name of Crispinus. Decker retaliated by a play entitled 'Satiromastix,' in which Jonson appears under the title of Young Horace. Jonson's tragedy of 'Sejanus' was produced in 1603, and his noble play of 'Volpone' appeared two years afterwards. About this time he was committed to prison with Chapman and Marston, the three poets having written the comedy of 'Eastward-hoe' (printed in Dodsley's collection), which contained some reflections on the Scots. They were in danger of losing their ears and noses, but were soon pardoned and released. It is said that Jonson's mother intended to poison herself, if the punishment had been inflicted. Being much occupied with court masques, in the writing of which he had acquired great celebrity, Jonson did not produce another play (in the strict sense of the word) till 1609, when his 'Epicœne' was acted, which is regarded by Dryden as a perfect comedy. 'The Alchemist' appeared in 1610, and though more deservedly reckoned one of the best of his works, was no great favourite with the public. Its ill success is ascribed by some to a party raised against him. Dryden has supposed that the 'Alchemist' was written in imitation of a piece called 'Albumazar' (in Dodsley's collection), but the style and general conduct of the two pieces are so very different that there scarcely seems a reason for supposing any imitation other than the mere circumstance that both plays satirize pretended adepts. It is a curious fact that the fine play of 'Albumazar' likewise met with no success. In 1611 appeared the tragedy of 'Catiline,' in which the long speeches translated from Cicero and Sallust called forth animadversions, which were disregarded by the author, as he gloried in plagiarisms which served to exhibit his learning. After the production of 'Bartholomew Fair' in 1614, and 'The Devil is an Ass' in 1616, he published his works in folio, and soon after retired to live in Christ Church, Oxford, whither he had been invited by several members. In 1619 he became poet laureate, and received an annual stipend of 100*l.* and a tierce of Spanish wine. The condemnation of 'The New Inn,' which he produced in 1625, nearly disgusted him with the stage, though he afterwards wrote 'The Magnetic Lady' and 'The Tale of a Tub,' which are considered inferior productions. He appears to have suffered much from poverty in the latter part of his life. He died on the 6th August, 1637, and was buried three days afterwards in Westminster Abbey. His monument, inscribed 'O Rare Ben Jonson,' is familiar to every person who has visited the Abbey.

Jonson's plays are well adapted to the perusal of earnest students, who will find in them a mine of sterling though often rugged beauty; but those will be disappointed who look to his works for the amusement of a passing hour. In the first place it requires a suitable education to enable a person to relish his imitations of the classic authors; and in the second, his plays do not so much represent human

character generally, as mankind under the particular circumstances of Jonson's own time, and many local allusions are made which cannot be understood without some knowledge of the manners and customs of the time: but Mr. Gifford's notes in his edition of Jonson are a treasure of this kind of information. The practice of exhibiting the 'humours,' that is, the peculiarities of character, obtained for Jonson the name of the 'humorous' poet, which name must be understood in a sense quite different from that in which it is used at present. The lovers of a more natural school of poetry are seldom admirers of Jonson, who finds his chief readers among those who like to observe the elaboration of dramatic art. Besides his completed dramatic works, Jonson has left two fragments, 'Mortimer's Fall,' which he intended to be a tragedy in the Greek style, and the 'Sad Shepherd,' a dramatic pastoral which is one of the gems of early English literature. He has also left a translation of Horace's 'Art of Poetry,' an 'English Grammar' of some merit, and a few poems, some of which are singularly beautiful. 'Every Man in his Humour' is the only piece that has kept possession of the stage. 'The Alchemist' has been abridged to a farce called 'The Tobacconist.'

JOPPA. [SYRIA.]

JORDAENS, JACOB, born at Antwerp in 1594, was a disciple of Adam van Oort, but was indebted to Rubens for the greater part of his knowledge in the art of painting. He was prevented from visiting Rome by an early marriage with Van Oort's daughter; but he diligently copied the best pictures of the great Italian masters to which he could procure access. His pictures are distinguished by powerful, brilliant, and harmonious colouring, as well as knowledge of chiaroscuro. His composition is rich, his touch free and spirited; but he is deficient in elegance and taste; he copied nature as he found it. He painted with great facility and rapidity, and being also extremely diligent and living to a great age (he died in 1678, aged eighty-four), his works are very numerous: a great many of the churches in the Netherlands have altar-pieces by him, and his pictures are met with in most collections of any eminence.

JORDAN. [SYRIA.]

JORTIN, JOHN, D.D (born 1698, died 1770), was of foreign extraction, his family having left France when Louis XIV. revoked the edict of Henry IV., commonly called the Edict of Nantes, for the protection of his Huguenot subjects. He was himself born in London. He had his grammar education at the Charter House, from whence he passed to Jesus College, Cambridge, of which he became in due time a Fellow.

While living at Cambridge he published a small volume of Latin poems, which are greatly admired, and allowed to possess a high rank among modern Latin verses. His College presented him to a living in Cambridgeshire, but he determined on leaving the country and residing in London, where he soon became an acceptable, or rather, in the better sense of the phrase, an admired and popular preacher. His sermons, many of which are printed, are distinguished for their excellent sense and the originality at once of thought and style. In 1751 he obtained the living of St. Dunstan in the East. His other church preferment was the living of Eastwell in Kent, presented to him by the earl of Winchelsea. This was for the greater part of his life all the preferment he enjoyed; but in 1762, when his friend Dr. Osbaldeston became bishop of London, Jortin was appointed his domestic chaplain, and was presented with a prebend in the church of Saint Paul and the living of Kensington. To these was soon added the archdeaconry of London. He fixed his residence at Kensington, and was buried in the new churchyard of that place.

The critical writings of Dr. Jortin are greatly admired by all who have a taste for curious literature. It is not merely on account of the learning which is displayed in them, and the use which is made of obscurer authors, but there is a terseness in the expression, and a light playful satire in the thoughts, which make them exceedingly entertaining. The first work of this class was published in 1731, and is entitled 'Miscellaneous Observations on Authors, antient and modern.' In 1751 the first volume appeared of his 'Remarks upon Ecclesiastical History;' and in 1758 he published his 'Life of Erasmus.

JORULLO. [MEXICO.]

JOSEPH I., of the house of Austria, emperor of Germany, succeeded his father Leopold I. in 1705. He carried on the war called that 'of the Spanish succession,' which had begun under his father, against Louis XIV. The allied armies under Eugene and Marlborough were prosperous in his reign. The battles of Ramilies, Oudenarde, and Malplaquet, the deliverance of Turin by Prince Eugene, the surrender of Naples to the Austrians, and the permanent footing obtained by the Archduke Charles in Spain, seemed to have nearly decided the question, when Joseph died of the smallpox in April, 1711, leaving his brother Charles, afterwards Charles VI., the last male heir of the house of Habsburg, to conclude the war. Joseph was a good prince; he was learned, and assiduous in the discharge of his duties, humane, and though a sincere Catholic, yet tolerant. He was one of the best of a house fertile in good and wise princes.

JOSEPH II., eldest son of Maria Theresa and of Francis of Lorraine, was elected king of the Romans in 1764, and in the following year, on the death of his father, he became emperor. As long as his mother lived he had little real power, as Maria Theresa retained the administration of her vast territories in her own hands; but on her decease, in 1780, he became possessed of all the hereditary Austrian dominions. Joseph soon displayed considerable ambition mixed with much restlessness: he was however kept in check by France and by Frederic of Prussia. After the latter died, in 1786, Joseph joined Catherine of Russia in a war against Turkey, which his general Laudon carried on with success, taking Belgrade and other fortresses in 1789. But the threatening aspect of affairs in France and Brabant arrested the progress of the Austrian armies, and Joseph himself died in 1790. The character in which Joseph is chiefly viewed is that of a reformer; in many instances a wise one, but in others rash and inconsiderate. He abolished all separate jurisdictions, and divided the Austrian monarchy into thirteen governments subdivided into circles, all under a uniform administration, civil and judicial. He abolished feudal servitudes, and substituted a fixed tax in lieu of corvées, taskworks, tithes, heriots, &c. He issued the edict of toleration, by which all Christians, of whatever denomination, were declared equally citizens, and equally eligible to all offices and dignities. Wherever there was a population of 3000 inhabitants, whether Protestants or Greeks, they were allowed to build a church for themselves, provided they established at the same time a permanent fund for the support of the minister and relief of the poor. The Jews were allowed the exercise of all trades and professions, with access to the public schools and universities. He took away from the clergy the censorship of the press, and gave it to a commission of literary men resident at Vienna. He opened colleges and universities, enlarged those already existing, endowed new professorships, and collected libraries. He encouraged manufactories, but, according to the old system, he placed exorbitant duties on foreign articles. He subjected the monastic fraternities to diocesan jurisdiction; and he suppressed many convents, but he did it harsh manner, without regard to the necessities and feelings of the older inmates, who were turned adrift into the world with only small pensions, and in some cases even without them. He forbade pilgrimages and processions, prohibited the pomp of funeral ceremonies, declared marriage to be a purely civil contract, forbade all papal bulls to be published throughout his dominions without the permission of the government, abolished the privileges of the university of Louvain, and established a new theological seminary in its place. These innovations, in a country so strongly attached to its old institutions and religion as the Belgian provinces were, led to an insurrection, and ultimately to the separation of those fine territories from the Austrian monarchy. His scheme of establishing the German as the universal language throughout his dominions led to a revolt in Hungary, which his more temperate successor Leopold had some difficulty in pacifying. In short, the reforms of Joseph partook both of the good and the evil of that spirit of innovation which has prevailed in Europe ever since his time; for with all his liberality he was perfectly despotic in carrying his measures into effect, without regard to the feelings, prejudices, or interests of individuals. He has been quaintly, but not inappropriately, styled the imperial avant-courier of the French revolution.

JOSEPH, King of Portugal. [PORTUGAL.]

JOSE'PHUS, FLA'VIUS, the celebrated Jewish historian, was born at Jerusalem A.D. 37. His family was one of very distinguished rank; by his mother's side he was de-

scended from the Asmonæan princes; and his father Matthias belonged to the chief sacerdotal family of the first of the twenty-four courses. Josephus was brought up at Jerusalem with his brother Matthias; and, according to his own account, he made such progress in learning that he was frequently consulted at the age of fourteen concerning difficult points in the law. At the age of sixteen he resolved to become acquainted with the opinions of the three principal Jewish sects, namely, those of the Pharisees, Sadducees, and Essenes. He accordingly studied the doctrines of each; but having heard that a celebrated Essene of the name of Banus lived in an ascectic manner in the desert, Josephus joined him in his solitary mode of life, and passed three years in his society. At the age of nineteen he again returned to Jerusalem, and embraced the opinions of the Pharisees. In his twenty-sixth year he sailed to Rome with the view of obtaining the liberation of some priests of his acquaintance, who had been seized by Felix, procurator of Judæa, and sent as captives to Rome. He had the misfortune to be shipwrecked in the Adriatic; but upon arriving at Puteoli, he became acquainted with an actor of the name of Aliturius, through whose means he was introduced to Poppæa, the wife of Nero, who procured the liberation of the priests, and bestowed many presents upon Josephus.

On his return to Jerusalem, Josephus found the greater part of his countrymen preparing for war against the Romans. Being strongly opposed to this measure, he joined himself to that party which was anxious for the preservation of peace. After the defeat of the Roman general Cestius, and the massacre of the Jews in Syria and Alexandria, all hope of peace appears to have been lost; and Josephus accordingly united himself to the war party. Being deputed, together with Joazar and Judas, to defend the province of Galilee, he made vigorous preparations against the Romans, though his plans were constantly thwarted, and his life frequently in danger from his personal and political enemies. On the approach of Vespasian's army in the following year, A.D. 67, Josephus retreated to Jotapata; and after defending the city for forty seven days against the whole Roman army, he was taken prisoner on the capture of the town. But instead of being put to death, as was the fate of all his companions, he was received by Vespasian with distinguished honour, in consequence of his pretending to the character of a prophet, and artfully predicting that Vespasian would shortly succeed Nero in the government of the Roman empire. He was present with Titus at the siege of Jerusalem, and endeavoured to prevail upon his countrymen to submit to the Romans. After Vespasian succeeded to the purple he was treated by Titus with still greater honour than before; but by the Jews he was regarded as a renegade, and by the Roman soldiers was looked upon with suspicion. On the taking of the city, Titus offered to grant him anything he wished. He asked for the sacred books, and the lives of his brother and fifty friends. He received a large estate in Judæa; and upon going to Rome was admitted to the privileges of a Roman citizen by Vespasian, who also gave him an annual pension and apartments in his own house. After the death of Vespasian, he continued to live in Rome in high favour with Titus and Domitian. The time of his death is uncertain; he was certainly alive at the latter end of the first, and probably at the beginning of the second century.

The first work published by Josephus was the history of the 'Jewish War;' it was originally written in the Syro-Chaldaic language for the use of those Jews who lived beyond the Euphrates. He afterwards translated it into Greek for the benefit of the learned Romans. The 'Jewish War' consists of seven books, and gives an account of the history of the Jews from the taking of Jerusalem by Antiochus Epiphanes to the destruction of the city by Titus. Many years afterwards, A.D. 93, Josephus published in Greek his great work on the 'Antiquities of the Jews,' with the view of increasing the reputation of his nation with the Romans, and of refuting the many calumnies in circulation against the Jews, by giving a faithful account of their history and opinions. This work commences, in the same manner as the book of *Genesis*, with the creation of the world; and it gives a consecutive account of Jewish history from the birth of Abraham to the commencement of the war with the Romans. The early part is taken from the books of the Old Testament, with many additions and explanations; some of which were probably genuine Jewish traditions; but the greater part appear to have been only added by the historian, in order to give more importance to his nation, and a greater air of probability to the miraculous occurrences in Jewish history. The 'Antiquities of the Jews' consists of twenty books, and was dedicated to Epaphroditus, a philosopher at Rome.

Josephus also wrote 'Two Books against Apion,' in reply to those Greeks who questioned the truth of the early part of his work on the 'Antiquities of the Jews.' He likewise published an account of his own life in answer to Justus, who had written in Greek an account of the Jewish war, in which he attacked the character of Josephus.

The best editions of Josephus are by Hudson, Oxf., 1720, 2 vols. fol.; Havercamp, Amst., 2 vols. fol; Oberthür, Leip., 3 vols. 8vo., 1782-5; and Richter, Leip., 6 vols. 12mo., 1826-7. The works of Josephus have been frequently translated into most of the modern languages of Europe: the best translations are—in French, by Gillet, Paris, 1756, 4 vols. 4to.; that in Italian, by Angiolini, Verona, 1779, 4 vols. 4to; and in English by Whiston. There are several German translations: one by J. B. Ott, Zürich, 1736; another by J. F. Costa, Tübingen, 1736; and the 'Jewish War,' by J. B. Frise Altona, 1804 5, 2 vols. 8vo.

JOSHUA (יְהוֹשֻׁעַ: in the LXX., Josephus, *Acts*, vii. 45, and *Hebr.* iv. 8, he is called Ἰησοῦς), a book of the Old Testament, so called because it records the exploits of Joshua, the son of Nun, who succeeded Moses in the command of the Israelites. Joshua, whose original name was Hoshea (הוֹשֵׁעַ, *Numb.* xiii. 8, 16), accompanied his countrymen from Egypt, and distinguished himself by his courage and military talents in a war with the Amalekites (*Exod.* xvii. 9 13). He was sent, together with several others, to explore the Promised Land, and was the only one of the spies, with the exception of Caleb, who exhorted his countrymen to invade Canaan (*Numb.*, xiv. 6-9, 38). In consequence of this he received especial marks of favour from God, and was nominated by Moses, on the express order of God, to succeed him in the command of the Israelitish army (*Numb.*, xxvii. 18-23; *Deut.*, iii. 28; xxxi. 23) Joshua led the Israelites over the Jordan, B C. 1451; and in the course of seven years conquered the greater part of Palestine, and assigned a particular part of the country to each of the tribes. He died at the age of 110, and was buried at Timnath-serath, in Mount Ephraim (*Josh.*, xxiv. 29, 30). We learn from Josephus that Joshua commanded the Israelites for twenty-five years (*Antiq.*, v. 1, sec. 29).

The author of the Book of Joshua and the time in which it was written are equally uncertain. Many critics have supposed that it was written by Joshua himself; but the entire book in its present form could not have been written by him, for many parts of the book refer to events which happened after the death of Joshua (*Josh*, iv. 9; xv. 13-19, compared with *Judg.*, i 10 15; *Josh*, xvi 10, with *Judg.*, i. 29; *Josh.*, xix 47, with *Judg.*, xviii. 29). Many critics suppose the book to have been written by Samuel or Eleazar, whose death is recorded in the last verse of the book: Lightfoot ascribes it to Phinehas, the son of Eleazar, and De Wette to the time of the Babylonish captivity. But at whatever time it may have been written, the author appears to have compiled the greater part, if not the whole, of the work from very antient documents, some of which were probably drawn up by Joshua himself. The survey of the conquered country is expressly said to have been 'described in a book' (*Josh.*, xviii. 9); and Joshua is also said to have written 'in the book of the law of God' the renewal of the covenant between God and the people of Israel (*Josh.*, xxiv 26). The Book of Jasher, which has long since been lost, is quoted in *Joshua* (x. 13) as a work of authority. In *Josh*, v. 1, the author appears to quote the exact words of a document written by a person who was present at the events recorded

The Book of Joshua is a continuation of the Book of Deuteronomy, and gives an account of Jewish history from the death of Moses to that of Joshua. It may be divided into three parts, of which the first contains the history of the conquest of the southern and northern parts of Palestine (chaps. i.-xi.), and a recapitulation of the conquests both of Moses and Joshua (ch. xii.); the second part gives a description of the whole of Palestine (ch. xiii.), and an account of the land which was allotted to Caleb and each of the tribes (chaps. xiv.-xxii); the third part contains an account of the dying address, death, and burial of Joshua (chaps. xxiii., xxiv.)

The canonical authority of this book has never been disputed. In all the MSS. of the Old Testament it immediately follows the Pentateuch.

Many Christian commentators consider Joshua to have been a type of Christ; but this opinion is not supported by any writer of the New Testament.

The Samaritans have two books which bear the name of Joshua. 1. One of these is a chronicle, consisting of forty-seven chapters, of Jewish history from a little before the death of Moses to the time of the Roman emperor Alexander Severus. It appears to have been called the Book of Joshua, because the history of Joshua occupies the greater part of the work (the first thirty-eight or thirty-nine chapters). It is written in the Arabic language, in Samaritan characters. Copies of this work are extremely scarce. The only copy in Europe, as far as we are aware, is in the University Library at Leyden, to which it was left by Joseph Scaliger. 2. The other Book of Joshua, written by one Abul-Phatah, is also a chronicle of events from the beginning of the world to A.H. 898 (A.D. 1492). There is a copy of this work in the Bodleian Library at Oxford. Schnurrer, who also possessed another copy, has given an account of the chronicle in the ninth volume of the 'Repertorium für Bibl. und Morgenl. Litt.'

(The *Introductions* of Eichhorn, Jahn, De Wette, Augusti, and Horne; Rosenmüller's *Scholia;* the best critical works on Joshua are by Masius, *Josuæ Imperatoris Historia illustrata*, Antwerp, 1574; Meyer, *Ueber die Bestandtheile und die Oekonomie des B. Josua*, with a review of the same book in Bertholdt's 'Journal der Theolog. Litt.' vol. ii., pp. 337-366; Herwerden's *Disputatio de Libro Josuæ*, Groning. 1826; Maurer's *Commentar über d. B. Josua*.)

JOUDPORE. [MARWAR.]

JOURNALS OF THE LORDS AND COMMONS. [PARLIAMENT.]

JOVELLA'NOS, GASPER MELCHIOR DE. This patriotic and enlightened writer and statesman, who zealously devoted his talents to the improvement of his countrymen and the defence of their liberties, was born at Gijon in the Asturias, in 1749. Although of noble lineage, being nephew to the duke of Losada, he possessed but a moderate patrimony; accordingly, as soon as he had completed his studies at the universities of Oviedo, Avila, and Alcala, he accepted the appointment of magistrate at Seville. Yet such were his economy and public spirit, that he would have declined the salary if he had not been pressed, and he appropriated a considerable portion of his emoluments to the 'Instituto Asturiano.' In 1778 he was made chief judge of the King's Court at Madrid, in which city he became acquainted with Cabarrus, Campomanes, and other eminent literary characters. He was afterwards removed, upon some futile pretexts, through the machinations of court intrigue, but was again recalled, and raised to the more important office of minister of grace, or home-secretary of state, to retain it however only for a few months, when the influence of the unprincipled Godoy expelled him. He now returned to Gijon, where his cares were directed towards the 'Instituto Asturiano,' which he had succeeded in establishing in 1794; yet he was not allowed to pursue his plans for public instruction long, since in about two years and a half afterwards he was arrested, and sent as prisoner to Majorca, where he was confined in the castle of Bellver. Even during this period, which continued upwards of seven years, he prosecuted his studies as diligently as circumstances would permit, and commenced a 'Flora Bellverica,' and collected materials for a history of the island. At length, after the downfal of Godoy, he was permitted to return by Ferdinand VII., and on that sovereign's abdication, was chosen member of the central junta. When that body was dissolved, the illustrious veteran returned to Gijon, to be shortly after driven from his home when the French invaded Asturias, in 1812. Within two months death liberated him from all his persecutors.

As a writer on subjects of political economy and legislation, Jovellanos stands foremost among his countrymen; but besides his productions of that class, he wrote numerous others, among which may be mentioned his celebrated 'Pan y Toros,' the tragedy of 'Pelayo,' the comedy of 'El Delincuente Honrado,' a translation of the first book of 'Paradise Lost,' besides several poetical pieces; an éloge on Ventura Rodriguez, the eminent architect; a dissertation on English architecture, &c. A biographical memoir of him was published by his friend Cean Bermudez (the well known author of several works on the fine arts), under the title of 'Memorias para la Vida del Exc. Sen. Don G Jovellanos, y Noticias analiticas de sus Obras.'

JOVIA'NUS, FLA'VIUS CLAU'DIUS, born A.D. 331, was the son of Veronianus, of an illustrious family of Mœsia, who had filled important offices under Constantius. Jovianus served in the army of Julian in his unlucky expedition against the Persians, and when that emperor was killed, A.D. 363, the soldiers proclaimed him his successor. His first task was to save the army, which was surrounded by the Persians, and in great distress for provisions. After repelling repeated attacks of the enemy, he willingly listened to proposals for peace, which were—that the Romans should give up the conquests of former emperors westward of the Tigris, and as far as the city of Nisibis, which was still in their hands, but was included in the territory to be surrendered up to Persia, and that moreover they should give no assistance to the king of Armenia, then at war with the Persians. These conditions, however offensive to Roman pride, Jovianus was obliged to submit to, as his soldiers were in the utmost destitution. It is a remarkable instance of the Roman notions of political honesty, that Eutropius reproaches Jovianus not so much with having given up the territory of the empire, as with having observed so humiliating a treaty after he had come out of his dangerous position, instead of renewing the war, as the Romans had constantly done on former occasions. Jovianus delivered Nisibis to the Persians, the inhabitants withdrawing to Amida, which became the chief Roman town in Mesopotamia. On his arrival at Antioch, Jovianus, who was of the Christian faith, revoked the edicts of Julian against the Christians. He also supported the orthodox or Nicene creed against the Arians, and he showed his favour to the bishops who had formerly suffered from the Arians, and especially to Athanasius, who visited him at Antioch. Having been acknowledged all over the empire, Jovianus, after staying some months at Antioch, set off during the winter to Constantinople, and, on his way, paid funeral honours to Julian's remains at Tarsus. He continued his journey in very severe cold, of which several of his attendants died. At Ancyra he assumed the consular dignity, but a few days after, being at a place called Dadastana in Galatia, he was found dead in his bed, as some say being suffocated by the vapour of the charcoal burning in his room, according to others by the steam of the plaster with which it had been newly laid, whilst others again suspected him to have been poisoned or killed by some of his guards. He died on the 16th of February, A.D. 364, being 33 years of age, after a reign of only seven months. The army proclaimed Valentinianus as his successor.

Coin of Jovianus.
British Museum. Actual Size. Gold.

JOVI'NUS, born of an illustrious family of Gaul, assumed the imperial title under the weak reign of Honorius, and placing himself at the head of a mixed army of Burgundians, Alemanni, Alani, &c., took possession of part of Gaul A.D. 411. Ataulphus, king of the Visigoths, offered to join Jovinus and share Gaul between them, but Jovinus having declined his alliance, Ataulphus made peace with Honorius, attacked and defeated Jovinus, and having taken him prisoner at Valence, delivered him to Dardanus, prefect of Gaul, who had him put to death at Narbo (Narbonne) A.D. 412.

JO'VIUS, PAUL. [GIOVIO.]

JUAN FERNANDEZ. [FERNANDEZ.]

JUAN DE ULLOA. [MEXICO.]

JUAN DEL RIO. [MEXICO.]

JUBA I., son of Hiempsal, king of Numidia, succeeded his father about the year 50 B C. He was a warm supporter of the senatorial party and Pompey, moved, it is said, by a gross insult which in his youth he had received from Cæsar. He gained, B.C. 49, a great victory over Curio, Cæsar's lieutenant in Africa. After the battle of Pharsalia and the death of Pompey, he continued steady to his cause; and when Cæsar invaded Africa, B.C. 46, he supported Scipio and Cato with all his power, and in the first instance reduced the dictator to much difficulty. The battle of Thapsus turned the scale however in Cæsar's favour. Juba fled; and finding that his subjects refused to receive him, put an end to his life in despair. His connection with Cato has suggested the underplot of Addison's tragedy

Coin of Juba I.
British Museum. Actual Size. Silve

JUBA II., his son, was carried to Rome by Cæsar, kindly treated, and well and learnedly educated. He gained the friendship and fought in the cause of Augustus, who gave him the kingdom of Mauritania, his paternal kingdom of Numidia having been erected into a Roman province. He cultivated diligently the arts of peace, was beloved by his subjects, and had a high reputation for learning. He wrote, in Greek, of Arabia, with observations on its natural history; of Assyria; of Rome; of painting and painters; of theatres; of the qualities of animals, on the source of the Nile, &c Juba married Cleopatra, the daughter of Antony and Cleopatra queen of Egypt. Their medal, which is here given, has IVBA REX on one side, and ΚΛΕΟΠΑΤΡΑ ΒΑCΙΛΙCCΑ on the other. Strabo in his 6th book speaks of Juba as living, and in his 17th and last book as then just dead. This would probably fix his death about A D. 17. (Clinton's *Fasti*; Dion Cass.; Cæs., *Bell Civ*; Pliny, *Hist. Nat.*, lib. v. 1, &c; see the Abbé Sevin, *Sur la Vie et les Ouvrages de Juba*, in *Acad. des Inscript*, vol. iv., p. 457.)

Coin of Juba II

JUDAH, JUDÆA. [JEWS; PALESTINE.]

JUDAISM includes, in its most extensive signification, not only the system of religion which is believed in by the Jews, but also all those laws, moral, civil, political, and ritual, which are contained in the five books of Moses. Some of the peculiar tenets of this religion were imparted to Abraham, the ancestor of the Jewish people; but it did not receive its full development till after the departure of the Israelites from Egypt and their arrival at Mount Sinai, where the Supreme Being imparted to Moses the whole system of the Jewish economy. After the destruction of Jerusalem by the Romans, and the dispersion of the Jews over the various countries of the world, all those laws which related to government, and which could only be enforced in a country where the Jews possessed political power, necessarily became obsolete; and the term Judaism has consequently been restricted to those religious and moral laws which are contained in the 'Pentateuch,' and which are recognised by the Jews to the present time as the rule of their faith and conduct. The peculiar characteristics of Judaism, with a history of its rise and progress, are given in the article JEWS.

An interesting account of the ceremonial rites and religious and philosophical opinions of the modern Jews (that is, of those who lived during and subsequently to the time of Christ) is given in Allen's 'Modern Judaism,' London, 1816, 2nd ed. 1830

JUDAS MACCABÆUS succeeded his father Mattathias (B.C. 166) as the leader of the Jews in their patriotic attempts to throw off the yoke of the Syrian kings (1 *Macc.* iii. 1). He greatly distinguished himself in the war by his military talents, his personal courage, and his implacable hostility to the Syrian princes. Immediately after his father's death he defeated two Syrian armies; and in the following year conquered Lysias and Gorgias, who had been sent against him with much larger forces. He afterwards took possession of Jerusalem, purified the Temple from all idolatrous pollutions, and restored the national worship. He strengthened his power by subduing the Idumæans and Ammonites and other nations bordering upon Palestine. The unexpected success of Judas greatly exasperated Antiochus, who swore that he would destroy the whole Jewish nation, but he died before he could make preparations for the conquest of the country. He was succeeded by Antiochus Eupator, who marched against Jerusalem, but was obliged to raise the siege and return to Upper Asia in consequence of a revolt of a powerful noble. Before he left Palestine he entered into an alliance with Judas. This treaty however was soon broken by the Syrian king; fresh armies were sent against Judas, which were all defeated by this intrepid warrior. Anxious to render Judæa independent, and feeling the difficulty of continuing the contest against the whole power of the Syrian empire, he sent ambassadors to Rome to solicit an alliance with the Roman people (1 *Macc.* i. 8; *Justin*, xxxvi. 3). This was readily granted by the Romans; but before Judas could receive any assistance from his new allies, Palestine was again invaded by a Syrian army of 22,000 men under the command of Bacchides. Judas had only 3000 men with him, and his number afterwards diminished to 800; but with these he ventured to attack the Syrians, and after an obstinate struggle was at length defeated, and perished in the contest (B.C. 160).

(*The First Book of the Maccabees*; Josephus's *Jewish Antiquities*; Prideaux's *Connexion*; Jahn's *Hebrew Commonwealth*.)

JUDE, THE EPISTLE OF SAINT, a book of the New Testament, was probably written by the Apostle Jude, who was surnamed Lebbæus (Λεββαῖος) and Thaddæus (Θαδδαῖος) (*Matt.*, x. 3; *Mark*, iii. 18; *John*, xix. 22). He is also called the brother of James (*Luke*, vi. 16; *Acts*, i. 13), and the brother of Christ (*Matt*, xiii. 55). This James was probably 'James the Less,' the son of Alphæus and Mary (*Matt.*, x. 3; xxvii. 56; *Mark*, xv. 40), who was also the brother of Christ. The meaning of the 'brother of Christ' has been already discussed under JAMES. It has however been maintained that this epistle could not have been written by the Apostle Jude, since he does not describe himself as an apostle, but, on the contrary, refers to the authority of the apostles as superior to his own (v. 17). (De Wette's *Lehrbuch*, sec. 182.)

The object of this epistle is to guard believers against the false teachers who had crept into the church, and to exhort them to persevere in their Christian profession. There is a great similarity between this epistle and the second epistle of St. Peter. Hug, in his Introduction to the New Testament, argues, that since 'the language of Jude is simple, unpremeditated, and expressive, without ornament; while that of Peter is artificial, and has the appearance of embellishment and amplification,' the epistle of Jude was written first, and was used by St. Peter in the composition of his second epistle. The epistle of Jude appears to have been written shortly before the destruction of Jerusalem.

The canonical authority of this epistle has been rejected by many, because the apocryphal books of Enoch and the Ascension of Moses are supposed to be quoted in it (v. 14, 9). It is not contained in the 'Peshito,' and is classed by Eusebius among the *Antilegomena* (*Hist. Ecc.*, ii. 23; iii. 25). Origen also expresses doubts respecting it (*Comment. in Matt.*, iii. 814); but the greater number of the fathers refer to it as a work of divine authority.

(The *Introductions* of Michaelis, Eichhorn, De Wette, Bertholdt, Hug, and Horne; and the *Commentaries* of Hänlein (1799) and Laurmann (1818).)

JUDEX, JUDI'CIUM. It is of some importance to form a correct notion of the terms *judex* and *judicium* in the Roman writers. The *judicia privata* were those in which one party claimed something of or against another party, and must be distinguished from the *judicia publica*. The former had relation to *actiones*, and may be generally described as Civil actions; the latter were of the nature of Criminal prosecutions.

In the Judicia Privata the party complainant (actor) came before the prætor or other magistrate who had jurisdiction (jurisdictio), and made his claim or complaint, to which the defendant (reus) might put in a plea (exceptio). The prætor then made an order by which he referred the matter to Judices or Recuperatores, or Arbitri, whose chief office was to ascertain the facts in dispute. The formula, or order of the prætor, was of the nature of a provisional decree: it stated the matter at issue between the parties and the judgment that was to follow upon the determination of the facts. The plaintiff had to prove his case, or the defendant to prove his plea, before the judices. Sometimes there was only one judex. The speech of Cicero 'Pro Publio Quintio' was made before a single judex, aided by assessors (consilium).

The patroni or orators appeared before the judices to support the cause of their clients. The judices were sworn to act impartially. Witnesses were produced on each side and examined orally; and it is clear from the remarks of Cicero (*Pro Cæcina*, c. 10), where he is commenting on the evidence in the case of Cæcina, that he had cross-examined and put to confusion an impudent witness on the other side (see also the Oration *Pro Flacco*, c. 10). It is clear also from the oration 'Pro Cæcina,' that the inquiry before the judices was public. Written documents, such as letters and books of accounts, were produced before the judices by way of evidence. (Cicero, *Pro Q. Roscio.*) When the orators had finished their speeches, the judices decided by a majority. The sentence was, if necessary, perhaps in some cases carried into effect by the lictors of the magistrate who appointed the judices. The form in which the judices pronounced their decision was that of a judgment or decree.

The difference between the judicium and arbitrium was this: in the judicium, the claim, demand, or damages, was a sum fixed; in the arbitrium it was a sum uncertain; and this difference was attended with certain variations in the procedure. This is very clearly expressed by Cicero (*Pro Q. Roscio*, c. 4).

The judices must necessarily to some extent have settled questions of law, inasmuch as the determination of the facts sometimes involved the interpretation of the law. They were accordingly allowed to have assessors (consilium) learned in the law (juris-consulti), but the juris-consulti merely advised the judices, who alone delivered the decision. In case of doubt as to the law, the judices might consult the magistrate under whom they were acting; but as to the matters of fact, the judices were the sole judges, and could take no advice from the magistrate (*Dig.*, v. 1. 79). Gellius (xiv. 2) gives an amusing account of the difficulty which he felt on being appointed a judex, and how he got rid of the business by declaring on oath, as the judex always might do, that he could not come to any decision. The difficulty which he experienced was exactly one of those which a person not practically acquainted with legal proceedings would experience.

We may presume that the judices were generally persons qualified by a sufficient education, though they were not necessarily lawyers; but it does not appear that they were named out of any determinate class, and there is good reason for thinking that both parties generally agreed upon the judices, or at least had the power of rejecting them. It would seem as if every Roman citizen was considered competent to discharge the functions of a judex in civil actions, at least under the emperors: but this part of the subject is not free from difficulty.

Appeals from the decisions of the judices were not uncommon. (Ulpian, *Dig.*, xlix. 1, 1; Scaevola, *Dig.*, xlix. 1, 28.)

So far seems pretty well ascertained. Such being the qualifications of the judices, and the magistrates who had 'jurisdictio' being only annual functionaries, it appears that there was no class of men among the Romans, like our judges, who were the living interpreters of law for a series of years in succession. The juris-consulti seem to have kept the Roman law together as a coherent body, and it is from their writings alone that the *Digest* is compiled. [JUSTINIAN'S LEGISLATION.]

A court is often mentioned by the Roman writers, the origin and constitution of which, if they could be thoroughly ascertained, would throw great light on the Roman judicial system, and indeed on the Roman polity generally. We allude to the Judicium Centumvirale, which in the earlier times of the Republic was a court in which weighty matters of law were decided. This court gradually declined, but was restored by Augustus. The author of the dialogue 'De Causis Corruptæ Eloquentiæ' speaks of it as most flourishing in his time; but he proves its former decay by observing that there was not a single speech then extant made by any great orator before this court, except one which he mentions. Yet both L. Crassus and Q. Scaevola had pleaded before the Centumviri. (Cic., *De Orat.*, i. 39.) The origin, number, and constitution of this body are not known, though some writers say that the number was 105, three being chosen from each tribe. (Festus, *v.* 'Centumviralia.') But there were not thirty-five tribes till A.U.C. 513, and therefore it might be inferred that the Centumviral body was of comparatively recent date. However this does not necessarily follow from the words of Festus; and besides, such an explanation may be nothing more than his attempt to assign the origin of the court, without being able to trace it historically. The Centumviri were not *magistratus*, but a college of *judices*, who decided in Judicia Privata. The matters which came before them were only *actiones in rem*, or *vindicationes*, not *actiones in personam*, or actions founded on contracts or delicts: consequently the matters brought before them were actions affecting ownership, servitutes (easements), wills, and intestacies. (Cicero, *De Oratore*, i. 38, 39.) The Querela Inofficiosi Testamenti seems to have come before this court only. So far as is here stated seems to be pretty clearly made out. A valuable essay on this subject by Hollweg will give further information, and solve with some degree of probability various difficulties that may suggest themselves to the student. (Hollweg, *Ueber die Competenz des Centumviralgerichts*, *Zeitschrift für Geschicht. Recht.*, v., 358.) A more recent writer (Tigerström, *De Judicibus apud Romanos*) dissents altogether from Hollweg's view of the court of the Centumviri, and perhaps on some points he has shown him to be wrong. The value of Tigerström's essay however appears to be rather in the numerous passages which he has collected from the Roman writers than in the deductions which he has made from them.

It is not our purpose to treat at length of the Judicia Publica. They were in the nature of criminal prosecutions, in which any person, not disqualified, might be the prosecutor, and in which the verdict was followed by a legal punishment. Judices were employed here also, and were a kind of assessors to the magistrate, or the Judex Quaestionis, who presided. Both the accuser and the accused, as it seems, might challenge a certain number of the judices. Witnesses were examined before them: slaves by torture, freemen orally. The judices, at least in the more important matters, voted by ballot: each judex put into the urn the tablet of Acquittal, of Condemnation, or the tablet N. L. (non liquet, 'it is not clear'), according to his pleasure. The magistrate pronounced the verdict according to the tablets which made a majority. A lively picture of the intrigues and bribery which were not unusual on such trials is given by Cicero in speaking of the affair of Clodius and the Bona Dea (*Ep. ad Attic.*, i. 13, 16). The various changes made as to the body from which the judices were chosen appear to refer only to the judicia publica. [EQUITES.]

There is a distinction between judicia publica, judicia popularia, judicia extraordinaria, and judicia populi.

The title 'De Officio Judicis' in the 'Institutes' (iv. 17) contains merely general directions for the conduct of the judices.

It should be observed that this subject is not free from difficulty. What is above stated must be taken only as correct in the main features. Further inquiry is still wanted on several matters connected with the functions of the judices. Enough has been said to enable the reader to compare the Roman judices with the modern jury, and to show the difference of the institutions.

(Gaius, lib. iv.; Heineccius, *Syntagma, &c.*, by Haubold; Unterholzner, *Ueber die Rede Cicero für den Schauspieler Roscius*, *Zeitschrift*, &c., i. 248; and his remarks on the difference between the *condictio* and the *actio in personam*, with reference to the *judices*; 'De Judiciis,' *Dig.*, v. 1; 'De Judiciis Publicis,' *Dig.*, xlviii.; *Instit.* iv., tit. 18.) [INTERDICT.]

Dr. Pettingall's 'Enquiry into the Use and Practice of Juries among the Greeks and Romans,' London, 1769, may be consulted as to the functions of the Roman judices in the Judicia Publica. The author's conclusions seem in the main to be correct, though his essay is an ill-arranged and unmethodical production. The 'Attische Process,' by Meier and Schömann, and the essay of Pettingall, may be

consulted with reference to the functions of the Attic Dicastæ.

JUDICIARY. [Courts.]

JUDGES, THE BOOK OF (שֹׁפְטִים: κριταί, *Acts*, xiii. 20), a book of the Old Testament, which gives an account of the history of the Israelites from the death of Joshua to that of Samson. Joshua did not exterminate according to divine commandment all the nations of Canaan, but allowed each tribe to settle in the district of land allotted to it before the termination of the war. Since the tribes were not united by any national league, and were surrounded by powerful enemies, they were frequently conquered by the neighbouring nations and obliged to pay tribute. But they seldom remained in subjection for any length of time; they still retained much of the valour by which they were originally distinguished; and their patriotic efforts were usually directed or supported by a series of individuals, who were remarkable either for craft, bodily strength, or daring valour. These persons were called *Shophetim*, which is not very well translated by our English word 'Judges;' since, with the exception of Deborah (*Judges*, iv. 4, 5), none of them appeared to have exercised the judicial office till the time of Eli, who was also high-priest. After they had delivered their countrymen from their oppressors, they usually retired into private life (*Judges*, viii. 23, 29).

The book of Joshua consists of two distinct parts. The first, after an introduction on the state of the Israelites after the death of Joshua (ch i., ii.), gives an account of the exploits of the different Judges from Othniel to Samson (ch. iii.-xvi.). There were thirteen Judges, excluding Abimelech, who was made king by the men of Shechem (ix. 6), namely: Othniel (iii. 9); Ehud (iii. 15); Shamgar (iii. 31); Deborah (iv. 4); Barak (iv. 6); Gideon (vi. 11); Tola (x. 1); Jair (x. 3); Jephthah (xii. 7); Ibzan (xii. 9); Elon (xii. 11); Abdon (xii. 13); Samson (xv. 20). The second part of the book (ch xvii.-xxi.) gives an account of an idol that was worshipped first in the family of Micah (ch. xvii.), and afterwards in the tribe of Dan (ch. xviii.); and also a history of a barbarous act committed by the Benjamites of Gibeah, which led to a war between the tribe of Benjamin and all the other tribes; in which the former was nearly extirpated.

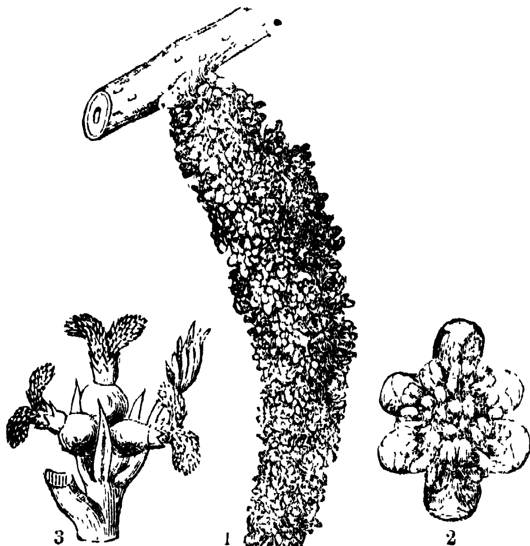
The author of the book and the time in which it was written are equally uncertain. It is commonly ascribed to Samuel, though some have argued, from *Judg.* xviii. 30, that it could not have been written till the time of the Babylonish captivity. It is probably however only a collection of different documents, composed at different periods; it does not give a continuous history of the people; and contains many things which could hardly have been written by the same individual. Many of its narratives are repeated in other books of the Old Testament; compare *Judg.* iv. 2; vi. 14; xi. 2, with 1 *Sam.* xii. 9-12; *Judg.* ix. 53, with 2 *Sam.* xi. 21; *Judg.* vii. 21, with *Is.* ix. 4; *Judg.* vii. 25, with *Ps.* lxxxiii. 11. Two or three verses in the song of Deborah are copied almost word for word in some of the Psalms; compare *Ps.* lxviii. 8, 9; xcvii. 5, with *Judg.* v. 4, 5.

The chronology of this book has occasioned considerable difficulty. The period of the Judges is usually estimated at 299 years, in consequence of a passage in the Book of Kings (1 *Kings*, vi. 1); in which it is said that 480 years elapsed from the departure of the Israelites from Egypt to the foundation of the temple by Solomon. St. Paul, on the contrary, gives 450 years as the period of the Judges (*Acts*, xiii. 20). The reader is referred for an excellent discussion of this subject to Michaelis's 'Chronologie des Buch der Richter,' in the 'Göttingisches Magazin' for 1780, p. 182; see also Michaelis's 'Orientalische Bibliothek,' b. v., p. 81.

The canonical authority of this book has never been disputed. It is placed in all the Hebrew MSS. immediately after the Book of Joshua. It is quoted by Philo and Josephus, and also by the author of the Epistle to the Hebrews (xi. 32).

(The *Introductions* of Eichhorn, Jahn, De Wette, Augusti, and Horne; Rosenmüller's *Scholia;* Serrarii *Judices et Ruth explanati*, Mainz, 1609, fol.; Schmidii *Commentar. in Jud.*, Strasb., 1684, 1706, 4to.)

JUDITH, an apocryphal book of the Old Testament, contains an account of the invasion of Syria and Judæa by Holofernes, general of Nabuchodonosor, king of the Assyrians, and particularly of the siege of Bethulia, a town in Judæa; and of the destruction of the Assyrian army, and the death of Holofernes through the courage and stratagem of Judith, the widow of Manasses, and an inhabitant of Bethulia. The historical and geographical difficulties of this book are so great, and its narrative so improbable, that a great number of critics are disposed to consider it as a religious romance, probably written in the time of the Maccabees, to encourage the Jews in their struggles against the Syrian monarchs. Grotius considers it as an allegory, written in the time of Antiochus Epiphanes; and that 'by Judith is meant Judæa; by Bethulia, the temple or house of God; and by the sword which went out from thence, the prayers of the saints; that Nabuchodnosor denotes the devil; and the kingdom of Assyria the devil's pride,' &c. Montfaucon (*La Verité de l'Histoire de Judith*), Huet (*Dem. ev. Prop.*, iv., p. 366), and Prideaux (*Connection*, vol. i., pp. 65-74), maintain, on the contrary, that it is a true history. Prideaux considers Nabuchodnosor to be the same person as Saosduchinus, the son of Esarhaddon, and grandson of Sennacherib; and Arphaxad, who is represented in Judith as the king of Media, to be only another name for Deioces. But in opposition to this it should be remarked that there are many passages in the book which refer to a time subsequent to the Babylonian captivity. Josephus also, who seldom neglects an opportunity of extolling the valour of his countrymen, takes no notice of this story.



The book of Judith was originally written in Chaldee, from which it was translated into Latin by Jerome. It was also translated into Greek and Syriac. The English translation in the authorized version was made from the Greek, and differs in many respects from the translation of Jerome, which is still extant in the Latin vulgate.

There is a great similarity between the history of Judith and a tale which Quintus Curtius tells us respecting the death of Spitamenes (viii. 3).

(The *Introductions* of Eichhorn, Jahn, De Wette, Bertholdt, and Horne.)

JUGGERNAUTH. [Vishnu.]

JUGLANDA'CEÆ are a natural order of apetalous Exogenous plants, consisting of trees or shrubs having eatable nuts and somewhat resinous leaves. The former are the walnuts and hickory nuts of the markets; the first produced by the genus Juglans, the latter by that called Carya. The leaves are alternate and pinnated; the flowers usually monœcious, those which are male collected in catkins. The calyx of the latter consists of a few scales attached obliquely to a single bract, and surrounding a variable number of stamens; that of the females is superior. The ovary is one-celled, and has one solitary erect ovule, which changes into a 4-lobed seed, with crumpled cotyledons, enclosed in a two-valved nut, clothed with a fleshy epicarp. The common walnut (Juglans regia), a native of Persia, is well known for its excellent timber, from which musket-stocks (and formerly cabinet-work) are manufactured, for its agreeable wholesome nuts, and the sweet drying oil which they furnish when pressed. Carya alba, the white Hiccory, bears nuts like those of the walnut, only smaller, smoother, and with a thicker shell, and furnishes a valuable tough elastic white timber much em-

Juglans regia.

1, a catkin of male flowers; 2, a single male flower; 3, a cluster of female flowers.

ployed in the construction of carriages and other vehicles. Other species of Hickory are also eaten, especially the Peccan nut, the produce of Carya olivaformis, a small and delicate sort. Although the fruit of these plants is eaten, it contains a purgative principle, which renders some of the species cathartic, as is the case with Juglans cathartica and nigra, two North American species; and even the common walnut participates so much in this quality, when the fruit is young, that a laxative conserve well known in domestic medicine is prepared from it. Juglans nigra, the Black American Walnut, is a tree of remarkable size and beauty.

JUGULAR VEINS are the large trunks by which the greater part of the blood is returned to the heart after having circulated in the head, face, and neck. There are two on each side, an external or superficial, and an internal or deep. The external jugular lies on each side just under the skin, and extends from near the angle of the jaw to the middle of the clavicle, behind which it opens into the subclavian vein. It conveys the blood of the confluent streams from the jaws, temples, and front and sides of the neck, and of some of those from the face. The internal jugular, which is far larger than the external, lies deep in the neck, by the side of the carotid artery. It receives all the blood from the skull and the brain, from the eyes and ears, and from the scalp, face, tongue, palate, pharynx, &c. The internal jugular veins extend from the base of the skull just in front of the vertebral column, down the neck, to some depth behind the clavicles, where they unite with the subclavian veins, by which all the blood is brought from the arms and upper part of the chest and neck to form the venæ innominatæ, which by their union form the vena cava superior, which opens directly into the right auricle of the heart. [HEART.]

JUGURTHA, the illegitimate son of Manastabal, by a concubine, and grandson of Masinissa, was brought up under the care of his uncle Micipsa, king of Numidia, who sent him with an auxiliary force to join Scipio Æmilianus, in his war against Numantia in Spain. Jugurtha so distinguished himself as to become a great favourite with Scipio, who, at the conclusion of the war, sent him back to Africa with strong recommendations to Micipsa. Micipsa adopted him, and declared him joint heir with his own two sons Adherbal and Hiempsal. After Micipsa's death (B.C. 118), Jugurtha, aspiring to the undivided possession of the kingdom, effected the murder of Hiempsal, and obliged Adherbal to escape to Rome, where he appealed to the senate. Jugurtha however found means to bribe many of the senators, and a commission was sent to Africa in order to divide Numidia between Jugurtha and Adherbal. The commissioners gave the best portion to Jugurtha, who, not long after their departure, invaded the territory of his cousin, defeated him, besieged him in Cirta, and having obliged him to surrender, put him to a cruel death; and this almost under the eyes of Scaurus and others, whom the Roman senate had sent as umpires between the two rivals (B.C. 112). This news created great irritation at Rome, and in the following year, under the consulship of Scipio Nasica and Calpurnius Bestia, war was declared against Jugurtha, and an army was sent to Africa under Calpurnius, accompanied by Scaurus, with other senators as his advisers. After some fighting, Jugurtha obtained under most favourable conditions the quiet possession of the usurped kingdom. The treaty however was not ratified at Rome; and Calpurnius being recalled, the new consul Posthumius Albinus was appointed to the command in Africa. Meantime Jugurtha, being summoned, appeared at Rome; but as he then succeeded in bribing several of the senators, and also Bæbius, a tribune of the people, no judgment was given. Jugurtha, emboldened by this success, caused Massiva, son of his uncle Gulussa, whom he suspected of aiming at his kingdom, to be assassinated in the Roman capital. The crime was traced to Jugurtha, but as he was in Rome under the public guarantee, the senate, instead of bringing him to trial, ordered him to leave Rome immediately.

It was then that Jugurtha is said to have exclaimed against the venality of that city, 'which would willingly sell itself if it could find a purchaser wealthy enough to bid for it.' Posthumius was sent to Africa to prosecute the war, but he soon returned to Rome without having effected anything, leaving the army under the command of his brother Aulus Posthumius, who allowed himself to be surprised in his camp by Jugurtha, to whom he surrendered himself; and his army, having passed under the yoke, evacuated Numidia. The new consul, Metellus, arriving soon after with fresh troops, carried on the war with great vigour, and being himself above temptation, reduced Jugurtha to the last extremity. Caius Marius was serving as lieutenant to Metellus, whom in the year B.C. 107 he supplanted in the command. Jugurtha meantime having allied himself with Bocchus king of Mauritania, continued to give full employment to the Romans. Marius took the towns of Capsa and Moluca, and in a hard contested battle defeated the two kings. Bocchus made offers of peace, and Marius sent to him his quæstor Sulla, who after much negotiation induced Bocchus to give up Jugurtha into the hands of the Romans as the price of his own peace and security. Bocchus hesitated awhile, but at last, having appointed a conference, he had Jugurtha seized and delivered over to the Romans. Jugurtha followed in chains, with his sons, the triumph of Marius, after which he was thrown into the Mamertine subterraneous dungeon, the soldiers having stripped him of all his clothes, and even torn his ears for the sake of the earrings which he wore. He was starved to death in his prison; or, as some say, he was strangled. His two sons were sent to Venusia, where they lived in obscurity. The war against Jugurtha lasted five years; it ended in the year 106 B.C. (Sallustius, *De Bello Jugurthino*; Eutropius.)

JULIA'NUS, FLA'VIUS CLAU'DIUS, son of Julius Constantius, brother of Constantine the Great, was born A.D. 331. After Constantine's death, the soldiers massacred the brothers, nephews, and other relatives of that prince, in order that the empire should pass undisputed to his sons. [CONSTANTIUS.] Two only escaped from this butchery, Julian, then six years old, and his half-brother Gallus, then thirteen years of age. Marcus, bishop of Arethusa, is said to have concealed them in a church. After a time Constantius exiled Gallus into Ionia, and entrusted Julian to the care of Eusebius, bishop of Nicomedia. Julian was instructed in Greek literature by Mardonius, a learned eunuch, who had been teacher to his mother Basilina. At the age of fourteen or fifteen he was sent to join his brother Gallus at Macellum, a castle in Cappadocia, where they were treated as princes, but closely watched. (Juliani *Opera*, *Epistle to the Athenians*.) The youths were taught the Scriptures, and were even ordained lecturers, and in that capacity publicly read the Bible in the church of Nicomedia. It appears that Constantius had the intention of making a priest of Julian, who had no inclination for that profession, and who is supposed to have already secretly abandoned the belief in the Christian doctrines. The death of Constans and Constantine having left Constantius sole master of the Roman world, that emperor, who was childless, sent for Gallus, in March, 351, and created him Cæsar, and he allowed Julian to return to Constantinople to finish his studies. There Julian met with the sophist Libanius, who afterwards became his friend and favourite. Constantius soon after again banished Julian to Nicomedia, where he became acquainted with some Platonist philosophers, who initiated him into their doctrines. He afterwards obtained leave to proceed to Athens, where he devoted himself entirely to study. After the tragical death of Gallus, in 355, Julian, who had again for a time awakened the jealous suspicions of his cousin, was recalled to court by the influence of the Empress Eusebia, his constant patroness, when Constantius named him Cæsar, and gave him the government of Gaul, which was then devastated by the German tribes, together with his sister Helena to wife. Julian made four campaigns against the Germans, in which he displayed great skill and valour, and freed Gaul from the barbarians, whom he pursued across the Rhine. He spent his winters at Lutetia (Paris), and became as much esteemed for his equitable and wise administration as for his military success. Constantius, always suspicious, ordered Julian to send him back some of the best legions in Gaul, to be employed against the Persians. When the time for marching came, in the year 360, Julian assembled the legions at Lutetia, and there bade them an affectionate farewell, when an insurrection broke out among the soldiers, who saluted him as Augustus. Julian immediately sent messengers to Constantius to deprecate his wrath, but the death of the emperor happening at the time left the throne open to him (A.D. 361). He proceeded to Constantinople, where, being proclaimed emperor in December, 361, he reformed the pomp and prodigality of the household, issued several wise edicts, corrected many abuses, and established a court at Chalcedon to in-

vestigate the conduct of those who had abused their influence under the preceding reign. Unfortunately some innocent men were confounded with the guilty; among others Ursulus, whose condemnation Ammianus (b. xxii.) deplores. On assuming the purple Julian had openly professed the old religion of Rome and sacrificed as high-priest to the gods, and though at the same time he had issued an edict of universal toleration, he soon showed a marked hostility to the Christians: he took the revenues from the churches, and ordered that those who had assisted in pulling down the heathen temples should rebuild them. This was a signal for a fearful re-action and persecution against the Christians in the provinces, where many were imprisoned, tormented, and even put to death. Julian restrained or punished some of these disorders, but with no very zealous hand. There was evidently a determined struggle throughout the empire between the old and the new religion, and Julian wished for the triumph of the former. He forbade the Christians to read or teach others the works of the antient classics, saying that as they rejected the gods they ought not to avail themselves of the learning and genius of those who believed in them (Juliani *Opera*, Epist. 42, Spanheim's edition). He also forbade the Christians filling any office, civil or military, and subjected them to other disabilities and humiliations. Julian has been called the Apostate, but it seems very doubtful whether at any period of his life after his boyhood he had been a Christian in his heart; the bad example of the court of Constantius, and the schisms and persecutions that broke out in the bosom of the church, may have turned him against religion itself, while his vanity, of which he had a considerable share, and which was stimulated by the praises of the sophists, made him probably consider himself as destined to revive both the old religion and the glories of the empire. That he was no believer in the vulgar mythological fables is evident from his writings, especially the piece called 'The Cæsars,' and yet he professed great zeal for the heathen divinities, and he wrote orations in praise of the mother of the gods and of the sun. Making every allowance for the difficulties of his position and the effect of early impressions, he may be fairly charged with a want of candour and of justice, and with much affectation bordering upon hypocrisy. If we choose to discard the invectives of Gregory of Nazianzus, of Cyril, and of Jerome, we may be allowed at least to judge him by the narrative of Ammianus, and by his own works, and the result is not favourable to his moral rectitude or sobriety of judgment. A learned and very temperate modern writer, Cardinal Gerdil, in his 'Considérations sur Julien,' in the 10th volume of his works, has so judged him; he has formed his opinion, not on the fathers, but upon the accounts of Julian's panegyrists, Libanius and other heathen writers.

Julian, having resolved on carrying on the war against the Persians, repaired to Antioch, where he resided for several months. His neglected attire, his uncombed beard, and the philosophical austerity of his habits, drew upon him the sarcasms of the corrupt population of Antioch. The emperor revenged himself by writing a satire against them, called 'Misopogon,' and, what was worse, by giving them a rapacious governor. He set off on his expedition with a brilliant army, reckoned at 65,000 men, crossed the Euphrates, took several fortified towns of Mesopotamia, crossed the Tigris and took Ctesiphon, but here his progress ended. The close Roman legions were harassed on all sides by the light cavalry of the Persians, and reduced to great distress for want of provisions. Still they presented a formidable front to the enemy, and Sapor, the Persian king, was inclined to come to terms, when in a skirmish between the advanced posts of both armies, Julian, who had run to head his soldiers, neglecting to put on his cuirass, received a mortal wound from a javelin which pierced his side. Being carried to his tent he expired the following night, 26th June, 363. He died with perfect calmness and composure, surrounded by his friends, conversing on philosophical subjects, and expressing his satisfaction at his own past conduct, since he had been at the head of the empire. His remains were carried to Tarsus in Cilicia, according to his directions, and his successor Jovian erected a monument to his memory.

Julian had many brilliant and some amiable qualities; his morals were pure and even austere; his faults were chiefly those of judgment, probably influenced by the impressions of early youth, an ardent and somewhat mystic imagination, and the flattery of those around him. His works consist of orations, satires, 'The Cæsars,' and about eighty letters, some of which are very interesting. His letter to Themistius contains a treatise on the duties of sovereigns. His narrative of his Gaulish and German campaigns is unfortunately lost. The last and best edition of Julian's works is by Ezech. Spanheim, Leipzig, 1696, fol.; but it does not contain all the letters. A complete edition of the letters was published by L. H. Heyler, Mainz, 1828, 8vo. There is a French translation of Julian's works by La Bletterie, and a Life of him by Tourlet.

Coins of Julianus. British Museum Actual Size.

JULIAN PERIOD is a term of years often employed in chronology, in order to avoid the ambiguity attendant on reckoning any time antecedent to our æra. The Julian Period consists of 7980 years, and is reckoned as having begun 4713 years before our æra; so that the present year 1838 corresponds to 6551 Jul. Per. The æra of the creation, or Anno Mundi, which has been used by Christian and Jewish writers, cannot be considered a fixed point, as chronologists and controversialists are not agreed as to the precise time of its commencement, some placing the creation 4004 years B.C., others, such as the early Alexandrian Christians, 5502 B.C., and the Greeks and Russians at 5508 B.C. The Julian Period is produced by the multiplication of the lunar cycle 19, solar cycle 28, and Roman indiction 15. [PERIOD OF REVOLUTION.]

JÜLICH-CLEVE-BERG, one of the two principal subdivisions of the province of Rhenish Prussia, and formerly considered a distinct province, has an area of 3584 square miles, and a population of 1,140,435 inhabitants. It is bounded on the north-west and west by the Netherlands, on the north-east and east by Westphalia, and on the south and south-west by the second subdivision of the province, *i.e.* the Lower Rhine. The principal river is the Rhine, which is joined by the Sieg, Wipper, Erft, Ruhr, and Lippe. The Niers, which falls into the Masa, and the Alte Yssel, likewise flow through parts of this province. The canals worth notice are the Fossa Eugeniana, which has fallen nearly into ruin, and the North Canal, not yet completed. The soil cannot be called fruitful, except in the vicinity of the Rhine, and in general on the left bank of the Rhine, where there are extensive plains; in the part on the right bank of the Rhine (with the exception of the small northern tracts) it is for the most part stony and mountainous, being traversed by chains which are branches of the Westerwald. But these mountainous tracts are the seat of the most flourishing manufactures, especially the former duchy of Berg, where the manufactories in the circle of Elberfeld alone give employment to 40,000 persons. The Wipperthal (valley of the Wipper), in this part, is indisputably the seat of the most active manufacturing industry in Germany, where Elberfeld, Gemarke, Barmen, Wipperfeld, and Reitershausen now almost form one connected town; and the finest buildings and the richest manufactories spring up every year. On the Rhine, near Königswinter, rises in singular forms, with seven summits, the Siebengebirge, viz. nearest the Rhine, the steep Drachenfels, 1473 feet high; then the Wolkenberg, 1482 feet; the Stromberg, with a chapel on the top; behind these, and rather farther from the Rhine, the Löwenberg, 1896 feet high; the Nieder or Nonnen-Stromberg; the Oelberg, 1827 feet high; and the Hemmerich. Ruins of antient castles are still seen on these mountains. This main subdivision of the Rhenish province consists of—1. the government of Düsseldorf, with an area of 2064 square miles, which now (1838) has 766,837 inhabitants, or 371 to the square mile; the city of Düsseldorf has 21,858 inhabitants; 2. the government of Cologne, with an area of

1520 square miles, and a population of 426,694 inhabitants; the city of Cologne has 69,051 inhabitants.

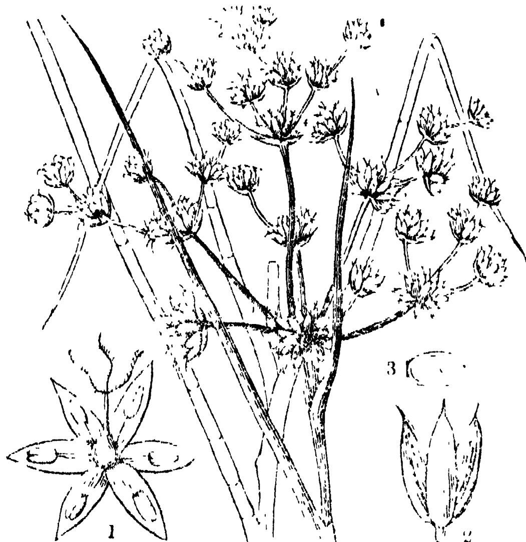
JU'LIUS I. succeeded Marcus in the see of Rome A.D. 336. Athanasius having been driven by the Eusebian party from his see of Alexandria, it was agreed by many of the Eastern bishops that the dispute should be settled in a council to be assembled at Rome. The council was convoked A.D. 340, and Athanasius appeared, but not his adversaries, who convened another synod at Antioch, which excluded Athanasius from his see. Julian remonstrated, but in vain. [ATHANASIUS, ST.] The general council of Sardica was next convened, but a schism soon broke out in that assembly, and the parties excommunicated each other. This is the council which is said to have granted to the see of Rome the right of arbitration in cases concerning the deposition of bishops; but this is a point much controverted. Julius died in the year 352. Two letters of his to the Eusebians and the Church of Alexandria are extant. (Constant., *Epistolæ Roman. Pontif.*) Others have been falsely attributed to him, as well as ten decretals, which are spurious.

JULIUS II., Cardinal della Rovere, nephew to Pope Sixtus IV., succeeded Pius III. in the year 1503. He had distinguished himself under preceding pontificates by his haughty temper and warlike disposition, which were fitter for the sword than the crosier. After his exaltation to the papal throne he began by driving Cesare Borgia out of his ill-gotten possessions in the Romagna; but there he found another power, the Venetians, who, during the preceding troubles, had taken possession of Ravenna, Rimini, and other places. The Venetians offered to pay tribute to the see of Rome for those territories, but Julius refused, and demanded their absolute restitution to the Church. After fruitless negotiations, Julius, in 1508, made a league with Louis XII., the Emperor Maximilian, and the duke of Ferrara, against Venice. This was called the League of Cambrai, and its object was the destruction of the republic of Venice and the partition of its territories. Venice however stood firm, although its armies were defeated and its territories were ravaged by both Germans and French with their usual atrocity. At last Julius himself, having recovered the town of Romagna, perceived the impolicy of uniting with ultramontane sovereigns against the oldest Italian state, and accordingly in February, 1510, he made peace with Venice. Wishing to undo the mischief which he had done, and to drive the foreigners, whom he styled 'barbarians,' out of Italy, he first sought to arm the Germans against the French, whom he dreaded most, but not succeeding, he called to his aid the Swiss. The pope himself took the field against the French in Lombardy, and attacked and took the town of La Mirandola, entering it by a breach, in January, 1511. The next campaign was unfavourable to Julius, and he lost Bologna. But in the following October his legates succeeded in forming a league, which he called 'holy,' with Ferdinand of Spain, Henry of England, the Venetians, and the Swiss. The campaign subsequent, in 1512, was marked by the battle of Ravenna and the death of Gaston de Foix, the French commander, followed by the total expulsion of the French from Lombardy. But this was effected by the Swiss, German, and Spanish troops, and Julius merely succeeded in driving one party of foreigners out of Italy by means of other foreigners, who meantime subverted the republic of Florence, and gave it to the Medici. In the midst of these events, Julius died of an inflammatory disease, on the 21st February, 1513. He was succeeded by Leo X. Julius was fond of the fine arts; he patronized Bramante, Michel Angelo, and Raphael, and he began the structure of St. Peter's Church.

JULIUS III., Cardinal Giocci, succeeded Paul III. in 1550. He re-opened the sittings of the Council of Trent, which had been suspended under his predecessor. He quarrelled with France and with Venice, and also with Ferdinand, king of the Romans and brother to Charles V., and died in March, 1555, leaving behind him a very indifferent character marked by incapacity and misconduct.

JULY, now the seventh, was originally the fifth month of the year, and was called by the Romans, in regard to its numerical station, *Quintilis*. Mark Antony altered the name to Julius, the gentile name of Caius Cæsar, the Dictator, who was born in it. So Festus, '*Julium mensem appellarunt quod eo mense dicitur Julius natus*.'

In the old Latin or Alban calendar, Quintilis had a complement of 36 days. Romulus reduced them to 31; Numa to 30; but Julius Cæsar restored the day of which Numa had deprived it, which it has ever since retained.

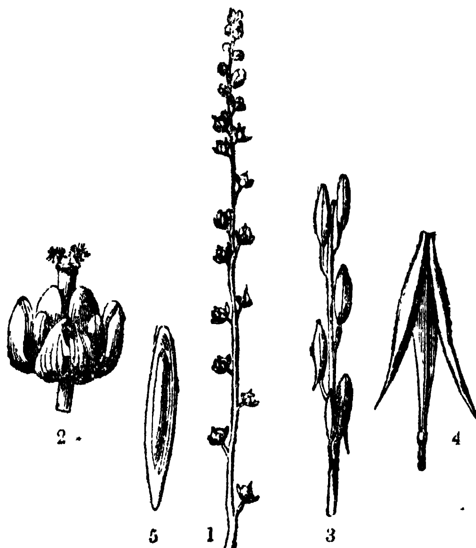


Our Anglo-Saxon ancestors called July *Mæd-monath*, 'mead month,' from the meads being then in their bloom; and *æftera-litha monath*, 'the latter mild month,' in contradistinction to June, which they considered and named as 'the former mild month.'

On the 3rd of this month the Dog-days are supposed to begin.

(Pitisci *Lexicon*, i. 985; Brady's *Clavis Calendaria*, i. 74; Bosworth's *Anglo-Saxon Dict.*, v. 'Monath.')

JUMNA. [HINDUSTAN.]



JUNCA'CEÆ, a small natural order of Endogenous plants, so named from Juncus, the rush, which is considered its type. It is principally composed of obscure herbaceous plants, with brown or green glumaceous hexandrous flowers, and would perhaps be with more propriety considered a section of Liliaceæ than a separate order. It forms one of the transitions from complete Endogens to the imperfect glumaceous form of that class.

Juncus articulatus.

1, a flower spread open; 2, a capsule; 3, a seed cut through its longer axis, showing the embryo.

JUNCAGINA'CEÆ are a small and unimportant order of Endogens, consisting of marsh plants with thin minute scaly flowers formed of 3 sepals, 3 petals, and as many stamens, which are opposite them. Their ovaries are 3 or 6 in number, contain each 1 or 2 ascending ovules, and, when ripe, form a dry fruit. The embryo has a lateral slit for the emission of the plumule, on which account they are

1, Triglochin palustre; 2, a flower magnified; 3, a spike of ripe fruit; 4, a ripe capsule; 5, a section of one of the cells of the capsule, with the seed enclosed in it.

regarded as allied to Araceæ. Triglochin is the commonest genus of the order, and inhabits the fresh or salt marshes of most parts of Europe.

JUNCUS ODORA'TUS. In old works on Materia Medica, as well as in many modern ones, we find a fragrant plant referred to under this name, and which is usually thought to be a kind of grass. Dr. Alston and some other writers gave as its synonymes Fœnum camelorum, Palea de Mecha, and more especially Schœnanthus, under which indeed it should be described, as it is with good reason thought to be Schœnus (σχοῖνος) of Dioscorides. See SCHŒNANTHUS, where also will be described the plant which appears to be the *Calamus aromaticus* of the antients, as the two are very closely allied.

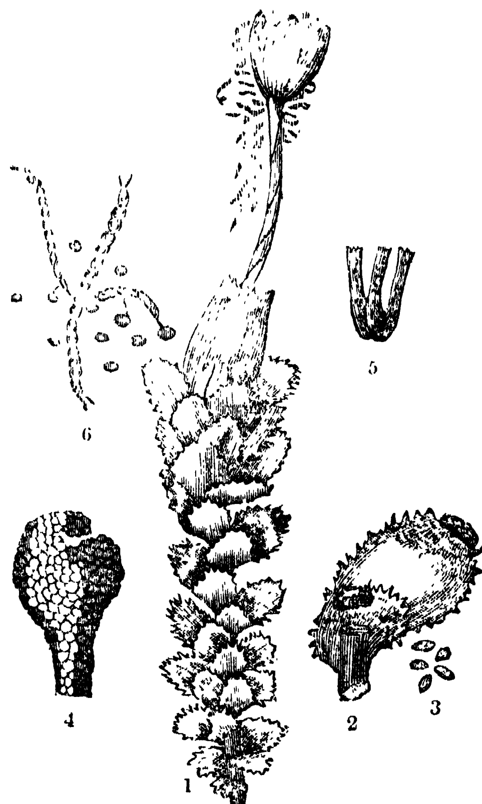
JUNE, the sixth month of the year, named from the Latin Junius. Ovid, in his *Fasti* (vi. 25), makes Juno assert that the name was expressly given in honour of herself.

> 'Ne tamen ignores vulgique errore trahamur,
> Junius à nostro nomine nomen habet'

In another part of the *Fasti* (vi. 87) he gives the derivation *à junioribus*; as May had been derived from *Majores*.

> 'Junius est juvenum; qui fuit ante senum'

Those who derive the name from Junius Brutus, who began his consulship in this month, forget that, according to tradition, it had received the appellation long before.



In the old Latin or Alban calendar June was the fourth month, and consisted of twenty-six days. Romulus is said to have assigned it a complement of thirty days. Numa, who made it the sixth month, deprived it of one day, which was restored by Julius Cæsar, since which time it has remained undisturbed.

The Anglo-Saxons had several names for the month of June. They called it *sear-monath*, 'dry month;' *midsumer-monath*, 'midsummer month;' and *æra-litha monath*, 'the other mild month,' in contradistinction to July.

In this month is the summer solstice. Pitiscus tells us that in the Roman times the month of June was considered to be 'nuptiis aptissimus.'

(Pitisci *Lexicon*, i. 986; Brady's *Clavis Calendaria*, i. 71; Bosworth's *Anglo-Saxon Dict.*, v. 'Monath.')

JUNGERMANNIA'CEÆ, a rather extensive natural order of Cryptogamic plants, or Acrogens, resembling mosses in appearance, but very distinct from them in many points of structure. Their foliage is much more cellular, their seed-vessel, or theca, splits into 4 valves, has no operculum, and instead of a central column has a number of tubes, each furnished internally with a double elastic spiral thread, and called an *elater*, to which the spores stick, and by the aid of which they are supposed to be dispersed. The species inhabit the trunks of trees, damp earth, or even the young shoots and leaves of other plants in cool moist climates, especially such as are temperate. Some have the stem and leaf formed into a frond, or thallus, resembling that of a lichen, but more commonly the species have leaves with stipules at their base. A large number of genera has of late been formed out of the old genus Jungermannia, but the opinions of botanists are much divided as to the value of these new divisions; and they have not been generally adopted. Hooker's *Monograph of the British Jungermanniæ* gives a valuable account of the species inhabiting these islands. A more recent account of the whole European genus is to be found in Nees v. Esenbeck's *Naturgeschichte der Europäischen Lebermoose*, 2 vols. 8vo. with plates.

Jungermannia nemorosa, highly magnified.

1, A branch in fruit. 2, A leaf, with sori upon it. 3, The contents of those sori. 4, The calyptra, before it is burst by the theca. 5, Abortive thecæ, in a very young state. 6, Elaters.

JUNI'PERUS, a genus of hardy, evergreen, woody plants, belonging to the natural order Coniferæ. Its distinctive character consists in its female fructification being succulent, consolidated, and reduced in the number of its parts below what is usual in the order to which the genus belongs. Like other Coniferæ, its fruit is composed of scales representing carpels spread open, and collected in a spiral manner round a common axis. But they are not more than six in number, generally three, and when ripe are fleshy and consolidated into a body resembling a drupe. In the language of the Pharmacopœia they are *berries*, in that of botanists they are termed *Galbuli*.

About twenty species are known, the most important of which are the following:

1. *J. Communis* (Common Juniper). This is a common bush, with long, narrow, sharp-pointed leaves, which are concave and glaucous on the upper side, but convex and green on their under, and with blackish fruit. It grows wild in all the northern parts of Europe, and, as is said, in North America also and the north of India, but it is doubtful whether the plants called Juniper by travellers in the Himalaya Mountains are not some other species. Occasionally the Juniper becomes a small tree. The fruit is used in considerable quantities in the preparation of gin, and in medicine as a powerful diuretic; a kind of beer called *genévrette* is also obtained in some parts of France by fermenting it with barley. Oil of Juniper, obtained from the Galbuli, is said to be the most powerful of all diuretics in doses of four drops.

2. *J. Sabina* (the Savin). This species is readily known from the last by its leaves being small, scale-like, and pressed close to the stem, besides which, its fruit is a light bluish green. It forms a compact gloomy-looking bush, in some cases spreading near the ground, in others acquiring the stature of a low tree. It is found wild in the middle of Europe and the west of Asia, inhabiting the most sterile soil, and is frequently met with in this country in shrubberies. Like the common Juniper, it is a diuretic and uterine stimulant, but is so powerful that its use is highly dangerous, except in the hands of regular practitioners. It is a well-known violent emmenagogue. Oil of Savin is a local irritant, producing blisters when applied to the skin; taken internally it is drastic and emetic.

3. *J. Virginiana* (the red cedar). Notwithstanding its popular name this is not generally the plant that yields the cedar wood used by cabinet-makers and pencil manufacturers, the Bermuda cedar being principally so employed, its timber however is of great excellence and durability. It is a native of North America, from Cedar Island in Lake Champlain as far as the southern side of the Gulf of Mexico, chiefly preferring the vicinity of the sea. In general it is a large bush; but in favourable situations, and in such a climate as that of Virginia and Carolina, it becomes a tree 40 feet high. The branches of this species are erect, the leaves arranged in threes, small, scale like, and but little spreading; the fruit is deep blue, covered with a mealy resinous powder. A great many fine plants occur in this country; it is not however with us an object of any importance to the forester, except for the sake of variety.

4. *J. Bermudiana* (the Bermuda red cedar). Very little known in Great Britain, in consequence of its not bearing the climate without protection. It is a native of the Ber

mudas, where it becomes a large tree, with a soft fragrant wood, the value of which is well known from its use in cabinet-work and the manufacture of pencils. It has, when young, long narrow spreading leaves growing in threes, but on the branches of old trees they become shorter, are placed in fours, and thus give the shoots a four-cornered appearance.

Of the other junipers, *J. excelsa* and *J. Chinensis* are handsome hardy trees; *J. Lusitanica* (the Goa cedar) is also of great beauty, because of its drooping habit and light grey branches, but it will not live long in England except in the warmest of the southern counties; and *J. Phœnicea* is a handsome bush: the others are of little moment.

JU'NIUS, FRANCISCUS. There are two learned persons of this name, father and son. The father was a Protestant minister in the Low Countries, best known by a translation of the Scriptures into the Latin tongue, in which he was assisted by Tremellius, whence it is usually called the version of Junius and Tremellius. He became professor of theology at Leyden, where he died in 1602. His son, the younger Francis Junius, of whom we are principally to speak, was born at Heidelberg in 1589, accompanied his father to Leyden, but soon relinquished study and embraced the profession of arms. On the cessation of hostilities in those countries in 1609 he gave up arms, and betook himself to literature as a profession. He came over to England in 1610, and was soon entertained as his librarian by Thomas Howard, earl of Arundel, a nobleman whose name, whenever it occurs, is found associated with some good deed connected with the higher interests of man. Junius remained 30 years in this honourable connection, during which time, having few distractions and an insatiable appetite for curious knowledge, he accumulated vast stores of information.

The more particular direction of his studies was towards the northern languages, or rather the various dialects of that great language which under the name of the Gothic or the Teutonic seems to have been spoken in the remotest ages by the people who inhabited both shores of the Baltic. We owe to him the publication of by far the most valuable relic of the literature of the people who spoke this language in what may be called its purity, a version of the gospels, commonly called Ulphilas' Version, and the manuscript which contains it, 'The Silver Codex.' This was printed with many learned notes and other illustrations in 1665. There is another work of his, published in his lifetime, on the 'Painting of the Antients,' which is a most useful book: but the work by which he is best known is a posthumous work, not printed indeed till 1743, entitled 'Etymologicum Anglicanum,' in which we have the investigation of the origin of numerous words in the English language, relics of the language spoken by our Saxon progenitors, conducted with an extraordinary apparatus of the knowledge required in such an undertaking. It was much used by Johnson.

Junius lived to his eighty-ninth year, dying in 1678, at Windsor, at the house of his nephew Isaac Vossius, another of the great names in the list of the really learned. He had formed a most valuable collection of manuscripts, which he bequeathed to the University of Oxford, and they are now among the treasures of the Bodleian Library.

JUNIUS'S LETTERS. [FRANCIS, SIR PHILIP.]

JUNO, a Roman divinity, whose attributes are nearly the same as those of the Grecian Hera. She was the daughter of Kronus and Rhea, the sister and wife of Jupiter, the goddess of marriage and childbirth, and the protectress of married women. Her worship was of very great antiquity at Argos and throughout the whole of the Peloponnesus. The Samians, as well as the Spartans, are supposed to have derived their knowledge of this deity from Argos (*Paus.*, iii. 13; vii. 4); and the same is said to have been the case with the inhabitants of Epidaurus, Ægina, and Byzantium (Müller's *Dorians*, i., p. 410, Eng. transl.). Her name also occurs in the early mythology of Corinth.

The two most celebrated temples of Juno were at Argos and Samos; the latter was the largest temple with which Herodotus was acquainted (*Herod.*, iii. 60). The Samians themselves denied that their knowledge of this deity was derived from Argos, and asserted that she was born in Samos. (*Paus.*, vii. 4.)

The marriage of Jupiter and Juno forms a prominent feature in the worship of this goddess. She was frequently represented veiled as a bride, and carried in processions, like a bride, on a car. Her favourite birds were the cuckoo and peacock.

She was worshipped at Rome with the epithets *Pronuba*, as presiding over marriage; *Lucina*, as bringing children to the light; and *Moneta*, as the warner, to whom a temple was erected on the spot where the house of Manlius Capitolinus stood (*Liv.*, vii. 28). The origin of the name *Moneta* is given by Cicero in his 'De Divinatione' (i. 45).

JUNO, the third in order of discovery of the small planets, discovered on the 1st of September, 1804, by Professor Harding, of Göttingen. This excellent astronomer, who died August 31, 1834, 'was of English extraction, and born at Lauenburg about the year 1763. He was originally educated for the Protestant Church; but having become tutor to the son of the illustrious Schröter, he was gradually attached to astronomy, and afterwards devoted himself exclusively to its practice and study. Having served for several years as assistant to Schröter, he became professor of astronomy in the university of Göttingen in 1805, and retained that chair till his demise, which catastrophe was hastened by excessive grief at the loss of his only child, a girl of fourteen years of age. The name of this amiable and active astronomer will be known through all ages as the discoverer of the planet Juno; and he compiled the most accurate celestial maps, especially of those parts where planets may be expected to appear, that are now extant.' (*Royal Astron. Soc. Annual Report* for 1835.)

It was while engaged in accurate and extensive observation of stars for the purpose, as it has been expressed, of forming a zodiac for the two new planets of Piazzi and Olbers, that Harding discovered the third; and this process gives the discovery a high degree of merit. [HERSCHEL.] The planet was, as in other cases, first supposed to be a star, until observation of it on two or three successive nights pointed out its motion. The planet itself is not visible to the naked eye, and it revolves round the sun in about 1593 days. [ASTRONOMY.]

Elements of Juno's Orbit.

Epoch 1842, May, 29^{d} 0^{h} mean astronomical time at Greenwich.

Long. of perihelion .	54	12	22 ·3	
Mean longitude . .	250	50	18 ·9	

Mean daily sidereal motion 813″·76167.

JU'PITER, the supreme Roman deity, known to the Greeks as Zeus, appears to have been originally an elemental divinity, who was worshipped as the god of rain, snow, lightning, &c. The etymology of the name, independent of other considerations, would lead us to this conclusion; since Jupiter was originally called Jov-is Pater, or Dies-piter, or Diu-piter, the *Diu* becoming softened in pronunciation into *Ju*, in the same manner as the Latin word *diurnus* has become *journal*. Jupiter, or Diupiter, would therefore mean the father of day or the air; the first part of the word contains the same root as the Latin adverb *diu* and adjective *diu-rnus*. This is also probably the original meaning of the Greek Ζεὺς and ΔιΓ-ὸς; though some have conjectured with considerable probability that Jov-is and Zeus are the same both in meaning and etymology as the Latin word deus. There is also a striking similarity, though probably accidental, between the word Jov-is and the Hebrew name of the supreme deity (יְהֹוָה). If there were any doubt respecting the original meaning of Ju-piter and Jov-is it would be sufficient to refer to those numerous passages in Latin authors in which the word is used in the signification of air (for example, Horace, *Od.* i., 1-25; Cicero, *De Nat. Deor.*, i. 15).

Cicero informs us (*De Nat. Deor.*, iii. 21) that there were three deities of the name of Jupiter: one the son of Æther; the second, the son of Heaven; and the third, the son of Saturn. The last was worshipped at Rome under various names, and many temples were erected to his honour, of which the most celebrated was the one on the Capitoline Hill, where he was worshipped under the name of Jupiter Optimus Maximus.

The Roman poets attributed to Jupiter the same power and attributes with which the Greeks invested Zeus. The Grecian Zeus was, according to Homer, the son of Kronus and Rhea. In order to save her son from being destroyed by his father, Rhea concealed him soon after his birth in a cave in Crete, where he passed the first years of his life.

As Zeus grew up, Kronos called to his aid the Titans, in order to secure his dominions against his son; but they were eventually conquered, and Saturn himself dethroned by the youthful Zeus. In the Homeric poems Zeus is represented as the supreme ruler of the heavens and the earth; and though subject himself to the degrees of fate, his commands cannot be disobeyed; his wisdom is infinite, and his power irresistible. His wife was Hera (Juno), and their children Hephæstus (Vulcan) and Ares (Mars). His worship was widely diffused throughout Greece.

Jupiter was usually represented as seated on an ivory throne, with a sceptre in his left hand and a thunderbolt in his right. The eagle, his favourite bird, was generally placed by the side of the throne.

JUPITER, the name of one of the old planets, the largest of all the bodies, except the sun, in the solar system. The astronomical history of this planet (or of any other, except the newly-discovered small planets) is so completely entangled in that of the progress of astronomy in general and pure mathematics, that it would be useless to attempt any separation. In the article GRAVITATION will be found the most remarkable points of what an astronomer would call the *theory* of Jupiter, meaning the explanation of his motions by means of the law of gravitation. We shall here confine ourselves to the statement of the elements of the planet's motion, and that of the satellites. [ASTRONOMY; GALILEO.] See also Baily's 'Astronomical Tables and Formulæ,' and Sir J. Herschel's 'Astronomy.'

The figure of Jupiter is sufficiently oblate to appear of a sensibly spheroidal form in a moderate telescope; the axis of revolution being to the equatorial diameter in the proportion of 167 to 177. The apparent equatorial diameter varies between half and three-quarters of a minute, being 36″·74, when the planet is at its mean distance from the earth. The real equatorial diameter is 10·86 times that of the earth, or upwards of 86,000 miles. It is nearly 1300 times as large as the earth, and its mean density is nearly the same as that of the sun, or about one quarter of that of the earth.

The mass of Jupiter, from the time of Newton to the present, was supposed to be to that of the sun in the proportion of 2 to 2141; but the recent observations of various astronomers, concluding with those of Mr. Airy contained in the late volumes of the Memoirs of the Astronomical Society, make it somewhat greater. Mr. Airy's result is that the mass of Jupiter is to that of the sun in the proportion of 1 to 1046·77, or 2 to 2094 nearly.

The planet revolves on its axis in $9^h\ 55^m\ 49^s·7$, and the inclination of its equator to the ecliptic is 3° 5′ 30″. Its light and heat are to those of the earth as 37 to 1000.

Elements of the Orbit of Jupiter.

Epoch 1799, December 31, 12^h mean astronomical time at Paris.

Semiaxis major 5·20115524, that of the earth being assumed as the unit.

Excentricity ·0481621; its secular increase (or increase in 100 years) ·0001594.

Inclination of the orbit to the ecliptic 1° 18′ 52″; its secular diminution 23″.

Longitudes from the mean equinox of the epoch (1.) of the ascending node 98° 25′ 44″·90; its secular increase (combined with the precession) 3430″; (2.) of the perihelion 11° 7′ 38″·26; its secular increase (combined with the precession) 5710″; (3.) of the planet (mean) 81° 52′ 19″·33.

Mean sidereal motion in 365¼ days 109256″·59; sidereal revolution 4332·5848212 mean solar days.

The four satellites of Jupiter appear to revolve on axes, each in the time of its revolution round the planet, in the same manner as our moon. The elements of their orbits are as follows (Baily, *Astron. Tables and Formulæ*): the units of time, length, and mass being the earth's mean solar day, the planet's equatorial semidiameter, and the planet's mass.

Sat.	Sideral Revolution.				Mean Distance.	Mass.
				More nearly.		
	d	h	m	d		
1	1	18	28	1·769137788148	6·04853	·0000173281
2	3	13	14	3·551810117849	9·62347	·0000232355
3	7	3	43	7·154552783970	15·35024	·0000884972
4	16	16	32	16·688769707084	26·99835	·0000426591

The first satellite has no sensible excentricity, and its orbit is very nearly indeed in the plane of Jupiter's equator. The second has no sensible excentricity; the inclination of its orbit to the planet's equator is under half a minute, and its nodes have a retrograde revolution of about thirty years. The third has a small but very variable excentricity, and the line of apsides has a direct but variable motion. The inclination of its orbit is under a quarter of a minute, and the nodes make a retrograde revolution in about 142 years. The fourth has a greater excentricity, and the direct mean motion of its apsides is nearly three-quarters of a degree per annum. The nodes made by its orbit with that of the planet have a direct motion of 4¾ minutes per annum, and the inclination of the orbit to that of Jupiter is 3° nearly. Sir J. Herschel gives as the mean apparent diameter of the planet and satellites 38″·327, 1″·105, 0′·911, 1″·488, and 1″·273; and as the diameter in miles, 87,000, 2508, 2068, 3377, 2890.

In consequence of the smallness of the angle by which Jupiter's equator is inclined to the ecliptic, and of the nearness of the orbits of the satellites to the plane of the equator, all the satellites, except the fourth, which sometimes escapes, undergo one eclipse once in every revolution. Since [ECLIPSE] this is caused by the entry of the satellite into Jupiter's shadow, the eclipse is independent of the earth's position, and the observation can certainly be made, unless Jupiter be too near to the sun. It is found that an immersion or emersion is not visible, generally speaking, unless Jupiter be as much as 8° above the horizon, and the sun as much as 8° below it. It never happens that both the immersion and emersion can be observed, in the case of the first satellite, and rarely in that of the second; though it is otherwise with the third and fourth. The reason is, that the planet itself always hides a part of its own shadow, and the first satellite is so near the planet that it must either enter or leave the shadow behind the planet: which also happens, for the most part, in the case of the second satellite. Before the planet is in opposition its shadow is on the western side of the planet, and after opposition on the eastern; while before the opposition immersions only are visible, and after opposition emersions, in the case of the first and second satellites. The eclipses of the four several satellites last about 2¼, 2¾, 3½, and 4¼ hours, one time with another. For the use of these eclipses in determining LONGITUDE, see that word.

When Jupiter is in or very near opposition, the planet itself hides its own shadow entirely, so that both immersion into and emersion out of the shadow may be invisible from the interposition of the planet; so that we then have the eclipse of an eclipse. And when the satellite passes between the sun and the planet, its shadow may throw a spot on the planet into darkness, which spot will appear to pass over the disc of the planet. Lastly, a satellite may pass between the planet and the earth, in which case it is seen sometimes as a bright and sometimes as a dark spot. The times of all these appearances are predicted in the Nautical Almanac.

JURA, an island of the Hebrides, in the district of Isla and shire of Argyle, bounded on the east by the Sound of Jura, and on the west by that of Isla. Its greatest length is less than thirty miles, and its average width about seven miles, being comprised between the latitudes of 55° 50′ and 56° 10′ north, and between the longitudes 5° 45′ and 6° 5′ west. The island is a continuous mountain range, elevated towards the south into five distinct points, of which the three principal are called the Paps, and rise to the height of 1083 feet. The flat land lies wholly on the eastern side of the island, and is estimated at less than one-twentieth of the entire surface: the rest consists of tracts of mountain pasture, intersected by many mountain torrents, and scarcely inhabited. Besides the great inlet of Loch Tarbet, the coast line is indented with several bays and harbours, the chief of which are Small Isles and Lowlandman's Bay. On the western shore are found large quantities of fine sand, which is much in request in the manufacture of glass. Large flocks of sheep and goats are fed upon the mountains, where also may be seen occasionally red deer, grouse, and other game. This island, with those of Collonsay, Scarba, Oronsay, and five other isles, constitute the parish of Jura, which, in 1831, contained 1312 inhabitants, the greater part of whom were employed in fishing. (MacCulloch's *Highlands*; *Beauties of Scotland*; *Population Returns*, &c.)

JURA, a department in the eastern part of France, on the frontier toward Switzerland. It is bounded on the north by the department of Haute Saône; on the north-east by that of Doubs; on the east by Switzerland; on the south by the department of Ain; on the west by that of Saône et Loire; and on the north-west by that of Côte d'Or. The greatest length is from north to south, from the bank of the Oignon near its junction with the Saône, to that of the Ain at the junction of the Valoux, 72 miles; its greatest breadth, at right angles to the length, is from the bank of the Seille, where it touches the frontier, to the neighbourhood of Nozeroy, about 41 miles. The area of the department is estimated at 252 square French leagues, or 1927 square English miles, rather greater than that of the English county of Northumberland. The population by the census of 1831 was 312,504, by that of 1836, 315,355, showing an increase in five years of 2851; and giving (in 1836) 164 inhabitants to a square mile. In density of population the department is just equal to the average of France, and superior to the English county with which we have compared it. Lons-le-Saunier, the chief town, is in 46° 40′ N. lat. and 5° 33′ E. long., 214 miles in a straight line south-east of Paris, or 241 miles by Provins, Troyes, Dijon, and Dôle.

The southern and eastern parts of the department are mountainous; the northern and western are more level. The Jura Mountains traverse the department and form three ridges of different elevations running from north-east to south-west. The loftiest summits, lying along the Swiss frontier, have an average elevation of nearly 4000 feet, and are covered with snow six months in the year: they present no soil capable of cultivation. The second ridge, covered for the most part with forests and thickets of pine, juniper, and box, has some fertile valleys and pasture grounds. The lowest ridge is covered with soil everywhere of good quality, and increasing in depth and fertility as it approaches the plain, which occupies the rest of the department.

The department belongs entirely to the basin of the Rhône: and the principal streams are the Oignon, the Doubs, and the Seille, affluents of the Saône, which joins the Rhône at Lyon; and the Ain, which falls into the Rhône several miles above that city. The Oignon flows for a few miles along the northern boundary of the department, which it separates from that of Haute Saône. The Doubs flows through the northern part of the department in a south-west direction past Dôle.

The Seille, which rises in the lower slopes of the Jura, near the centre of the department, waters the western side. The Ain rises just in the southern part of the department amid the heights of the Jura, not far from St. Claude, and flows first north, then west, and then south into the department of Ain. None of the rivers of the department are navigable except the Ain for about seven or eight miles. There is one canal, that which unites the Rhône and the Rhine, about 25 miles of which are in the department. It passes from the Saône to the valley of the Doubs near Dôle, and follows the course of that valley into the department of Doubs.

The principal road in the department is that from Paris by Dijon to Geneva. It enters the department on the north side between Auxonne (dep. of Côte d'Or) and Dôle, passes through Dôle, Mont-sous-Vaudrey, Poligny, Montrond, Champagnole, Maison Neuve, St. Laurent, Morey, Les Rousses, and La Valtay: between these last two towns it crosses a part of Switzerland, and beyond La Valtay enters the department of Ain. A branch of this road runs to Lons-le-Saunier, and rejoins the high road at St. Laurent; other branches lead to Arbois and Salins; roads lead from Dôle and Lons-le-Saunier to other towns in this and the neighbouring departments. The aggregate length of the government roads is 206 miles, of which about two-thirds are out of repair, and one-sixth unfinished, leaving only one-sixth in a fit state for use. The Routes Départementales have an aggregate length of 338 miles, all, except seven miles of unfinished road, in good repair. The bye-roads and paths have an aggregate length of nearly 3600 miles. The department would be rather better furnished with roads than the average of the departments, if they were kept in proper repair.

The north-western portion of the department is occupied by the strata above the chalk; the rest of the department by the strata between the chalk and the new red or saliferous sandstone: the chalk formation itself does not appear to occupy any part of the surface. (*Carte Physique et Minéralogique de France; Atlas to* Malte Brun's *Précis de Géographie.*) The mineral treasures of the department are considerable. Many iron-mines are worked; lead and coal are found, but not worked, and there are some traces of gold. Various species of marble of great variety and beauty, and alabaster, are quarried; also lithographic stones. Peat is dug; and there are several brine springs the water of the springs of Salins yields 15 per cent. in weight of salt.

The climate of the department varies materially in different parts, according to the elevation of the surface. In general the winters are long, owing to the snow which remains on the mountains till April; and the temperature, even in the plains, is colder than the latitude would lead one to expect. The spring is short, and the summer hot; the air, which in the plain is moist and close, is fresh and pure on the lower slopes, and dry and keen in the higher ridges, where the seasons are reduced to two, a winter of eight months and a summer of four.

The agricultural produce is sufficient for the consumption of the department. The harvests in the plain are very abundant, and consist of wheat, rye, buckwheat, and maize. On the lower hills they consist of barley, oats, maize; rape seed is also grown here. In the higher ridges of the mountains, where there is any cultivation, the crops are very scanty; some barley and oats, and, in favourable spots, a little wheat and hemp, are grown. The vine is cultivated on the lower slopes of the mountains, and the quantity of wine produced is greater than the consumption. It is chiefly white wine, and is of good quality; that of Arbois is creaming and sparkling, like champagne. The walnut is raised on the lower hills. The quantity of woodland is considerable: the principal forests are that of Chaux, in the northern part of the department, between the Oignon and the Loue; and the contiguous forests of Moydon, Arbois, and Poligny, in the centre of the department. The trees are chiefly the pine and the oak.

The quantity of horned cattle is great, especially of cows. The butter is very good, and much cheese is made. The number of sheep is comparatively small: the long-woolled English sheep have however been lately introduced, and with good success. Horses are tolerably numerous, and some mules are bred. Poultry and bees are objects of considerable attention, especially bees in the mountain country, where they yield excellent honey. The forests yield game and wild animals, including the wild boar, the wolf, the fallow-deer, and a few roebucks; and the rivers and lakes abound with fish, especially excellent crayfish.

The department is divided into four arrondissements, as follows:—

Arrondissement.	Situation.	Area in sq miles.	Population in 1836.	Communes
Lons-le-Saunier	W. & S.W.	596	107,690	207
Poligny . . .	E.	482	80,672	149
St. Claude . .	S.E.	405	52,353	82
Dôle . . .	N.	444	74,640	137
		1927	315,355	575

It is divided into thirty-two cantons, or districts under a justice of the peace.

In the arrondissement of Lons-le-Saunier are Lons-le-Saunier on the Vaille (population in 1836, 7684); Orgelet, near the Valouze (pop. 1928 town, 2367 whole commune), St. Amour, in the south-western corner of the department (pop. 1957 town, 2595 whole commune), Scellières, on the Brene, a feeder of the Seille; Bletterand, Arlay, and Château Châlon, on or near the Seille; Conliege on the Vaille; Clairvaux, on the Drouene, a feeder of the Ain; Cousance, on a small affluent of the Solnan, a tributary of the Seille belonging to the adjacent department of Saône and Loire; Gigny and St. Julien, on the Suran, a feeder of the Ain; and Arinthaux, or Arinthod, near the Valouse.

Lons-le-Saunier, the capital of the department, took its rise in the fourth century from the salt-works, which are still of great importance. It is situated at the confluence of three small streams in a fertile valley, surrounded by vineyards. The principal buildings are the church on the parade, a fine hospital, capable of accommodating a hundred and fifty patients, and the salt-works. There are neat fountains, a library, a museum, a high-school, a theatre, and an agricultural society. Lons-le-Saunier is one of the chief places

of trade in the department: a considerable quantity of paper, card-board, leather, cheese, and iron is manufactured in the town or neighbourhood. At St. Amour several festivals and usages, which may be traced to the remotest antiquity, are still observed. Arinthaux is built on the site of an antient Gaulish temple. Clairvaux was formerly celebrated for its abbey. [CLAIRVAUX.] In its neighbourhood are considerable iron-works, where nails are manufactured by machinery.

In the arrondissement of Poligny are, Poligny, on the Glantine (population, in 1836, 6492), Arbois, near the source of the Vieille, a small affluent of the Cuisance (pop. 6464 town, 6741 whole commune), Salins, on the Furieuse (pop. 5759 town, 6554 whole commune), and Nozeroy, on a small feeder of the Ain.

Poligny appears to have been a place of some note in the latter period of the Roman empire, and is perhaps the Castrum-Olinum of the Notitia Imperii, the residence of the Roman governor of the province of Maxima Sequanorum. Poligny was the summer residence of the dukes of Bourgogne. This town is regularly laid out, and is adorned with several fountains, which contribute to the cleanliness of the place. The inhabitants manufacture hosiery, nails, earthenware, and turnery wares in wood and metal. The environs of the town are rich in monuments of antiquity: among them are two druidical stones, which the superstition of the surrounding peasantry still supposes to revolve on their centres at the yearly celebration of the midnight mass. There are the remains of vast Roman buildings, the purpose of which is unknown. Arbois is a handsome town, the inhabitants of which manufacture paper and porcelain. The town has many relics of Gaulish and Roman buildings, and the ruins of an antient castle of the middle ages. Large quantities of vegetables and flowers are grown round Arbois. The wine has been noticed already. It was the birthplace of Pichegru. Salins owes its name and prosperity to its brine springs, which were well known as early as the sixth century. This town was almost entirely destroyed by fire in A.D. 1825. The hospital, the high-school, and the salt-works were almost the only buildings that escaped destruction, except in the suburbs, which were not injured. The loss in houses and furniture was estimated at 300,000*l.* Subscriptions were opened all over France, and above 80,000*l.* was promptly subscribed: the inhabitants energetically betook themselves to the rebuilding of the town; by day they worked at clearing away the ruins, and at night they assembled in one of the rooms of the high-school to receive instructions from a fellow-townsman, a soldier who had been educated in the Polytechnic school at Paris, in those principles of geometrical and mechanical science which would enable them to rebuild their houses in the easiest and most economical manner. Salins was rebuilt; a wide street, with a foot-pavement, an unusual thing in France, extends the whole length of the town, and there are fountains in the open spaces, of simple construction, but in good taste. The houses are well built. Salins is walled and defended by two forts, Fort St. André and Fort Belin.

In the arrondissement of St. Claude are St. Claude, on the Bienne (pop. in 1836, 5238), Moyrans, near the Ain, and Morez, near the Bienne, on a torrent called the Bief de la Chaille, which flows into that river. St. Claude is described elsewhere. [CLAUDE, ST.] Morez is in a long defile of the Jura, so narrow as barely to allow the requisite width for the street and the houses that skirt it on each side, behind which the mountains rise almost perpendicularly to the height of 1200 feet. Brass-wire, pins, clocks, watches, and roasting-jacks are made here.

In the arrondissement of Dôle are Dôle (pop. in 1836, 10,137), and Rochefort, on the Doubs; and Chaussin on the Dorain. Dôle is described elsewhere. [DÔLE.] The other two towns are unimportant.

The manufactures of the department are carried on with great activity. There are several iron-works. Wrought and cast iron and steel are manufactured: nails and heavy iron goods are made. Clocks and watches, spectacle-frames, and roasting jacks are made at Morez, at Foncine le Haut, and Foncine le Bas, in the arrondissement of Poligny. In the arrondissement of St. Claude, turnery wares, and toys in ivory, bone, box, and other woods, horn, &c. are made. At Sept Moncel, in the same arrondissement, five hundred persons are engaged in the manufacture of artificial gems. The other manufactures of the department are cotton stockings, hats, coarse linens, chamois and other leather, paper, brandy, glue, mineral acids, soap, &c. The chief exports consist of the above-mentioned articles, especially iron goods, toys, and watches; wine, timber, and deals; horses for the cavalry, and horned cattle. A number of the inhabitants emigrate yearly to other parts of France, and follow the calling of lime-burners, plasterers, hemp-dressers, and curriers; returning home at the time of harvest.

This department forms the diocese of St. Claude, the bishop of which is a suffragan of the archbishop of Lyon et Vienne; it is in the jurisdiction of the Cour Royale, and the circuit of the Académie Universitaire of Besançon, and is comprehended in the sixth military division, of which the head-quarters are at Besançon. It returns four members to the Chamber of Deputies.

In respect of education this department is the third in France. Of the young men enrolled in the military census of 1828-29, seventy-three in every hundred could read and write.

This department formed part of the territory of the Sequani, one of the principal nations of the great Celtic stock. Under the Roman dominion it made part of the province of Maxima Sequanorum, a subdivision of Gallia Lugdunensis, or Celtica. It subsequently passed into the hands of the Burgundians and the Franks; and in the middle ages made part of the province of the county of Bourgogne, or Franche Comte. [BOURGOGNE; BURGUNDIANS; FRANCE, FRANCHE COMPTE.]

JURA MOUNTAINS. The range of elevated ground to which this name peculiarly applies lies to the west of the Lakes of Geneva and Neufchâtel, and may be described as a broad limestone ridge, swelling at several points to more than 5000 feet above the sea. The Mont Dôle, north-west of Geneva, is about 5500 feet, and the Mont Reculet, west of Geneva, is still higher. If to this region we give the name of the 'Swiss Jura,' the continuation of the same limestone country though Suabia and Franconia will be properly distinguished as the 'German Jura,' rising in the Rauhe Alp, near Ulm, to 2400 feet above the sea. The general direction of these calcareous mountains is north-eastward, but in Franconia it changes to a northward course; their boundaries are little sinuous; their breadth averages about 20 miles, and from the vicinity of Bamberg to the passage of the Rhone the length exceeds 400 miles. In a south-westward direction similar limestone rocks extend to the vicinity of Narbonne, about 140 miles farther, making the whole range of the Jura and its physically related rocks about 550 miles.

Nearly parallel to the Swiss and German Jura on the south, calcareous rocks, belonging to the same geological æra, range in front of the primary rocks of the Alps, from Chambery to Vienna, more than 500 miles; and similar ranges of the same strata occupy the right side of the Saône and the left of the Meurthe and Moselle, and connect themselves with the oolites which encircle the basin of Paris. Thus the Helvetic Jura occupies a nearly central position with respect to an immense and ramified system of elevated limestone districts, all belonging to one geological system; and hence it has become the almost universal practice of the continental geologists to designate that series of rocks by the title of the 'Jura formation,' which corresponds exactly to the 'oolitic system' of our general table. [GEOLOGY.]

The mountains of the German, Swiss, and French Jura, regarded in a general point of view, may be described as enclosing between their ranges an immense basin, which contains the greater portion of Burgundy and Lorraine, the whole of Alsace, Suabia, Franconia, and Hesse. Against this enclosed region the oolitic ranges present bold and abrupt descents, while toward the exterior the slopes are gentle. The chalk formation partially surrounds the Jura ranges on the French and German sides, but in the interior of the basin not a trace of it is to be found, and Von Buch believes that the Jura Mountains stood up amid the waters of the sea at the time of the deposition of the cretaceous system of rocks, nearly as we may suppose the coral reef of New Holland would appear if elevated by subterranean forces. (*Verhandlungen der Königl. Akademie der Wissenschaften zu Berlin*, 1838.) M. Boué had previously recognised the antiquity of the elevation of the German Jura, in discussing the characters of the Bavarian tertiary region. (*Proceedings of the Geological Society of London*, 1830.) And M. E. de Beaumont, from a general contem-

plation of the phenomena on the line of the Jura Mountains, adopted the conclusion that from the Cevennes through the Swiss and German Jura, perhaps even to the Erzgebirge, dislocations of considerable importance occurred, ranging north-east and south-west, after the deposition of the oolites and before the deposition of the chalk. (*Sur les Révolutions du Globe, in Annales des Sciences Naturelles*, 1827.)

Von Buch observes that the Swiss, Suabian, and Franconian divisions of the Jura Mountains have each their peculiar characters. In the Swiss Jura the strata are thrown up at high angles of elevation, and consequently form long extended ridges and chains; the Suabian region is formed of rocks which lie in regular and nearly horizontal layers, and constitute an extended and uniform plateau; in Franconia dolomite abounds, and crowns the heights with picturesque rocks, resembling the towers and pinnacles of ruined castles. The mineral composition of the Jura ranges is everywhere similar; and, when minutely analyzed, may be considered as forming a series of terms severally comparable to the larger divisions of the oolitic series of England and Normandy.

According to M. Thurman, 1832 (De la Beche's *Manual*), the central part of the Jura (at Porentruy) contains—

Fine oolites and compact limestones, equivalent to the 'Portland oolite.'
Marls and marly limestones, equivalent to 'Kimmeridge clay.'
Compact oolitic and coralline limestones, equivalent to the 'Oxford oolite,' &c.
Marly and sandy limestones, equivalent to the 'calcareous grit.'
Blue marls, limestones, ferruginous oolite, equivalent to 'Oxford clay.'
Oolitic shelly limestones, sandy limestones and marls, equivalent to the 'Cornbrash and forest marble' groups.
Fine-grained oolite, equivalent to the 'Bath great oolite.'
Marls and calcareous beds, equivalent to the 'Fullers' earth.'
Oolite, partly ferruginous, equivalent to the 'inferior oolite.'
Micaceous sandstones and marls, equivalent to the 'sand below inferior oolite.'
Lias.

This coincides very nearly with M. Thirria's notice of the series in Haute Saône.

According to M. Boué (1830), the German Jura contains the subdivisions of the oolitic series from the lias upward to the cornbrash. He thus includes in the Bath oolitic formation [GEOLOGY] the dolomitic limestones of Franconia, and the lithographic slates of Solonhofen, even more celebrated for their numerous tortoises, Pterodactyli, fishes, crustacea, ammonites, belemnites, insects, algæ, and other fossils, than the supposed equivalent beds of Stonesfield.

On these points M. Boué appears to be supported by Mr. Murchison (*Geol. Proceedings*, 1831); Von Buch regards the dolomites and lithographic slates as constituting a distinct upper band of the 'Jura formation' (corresponding to the Oxford and Portland oolites), and some of the highest layers of this group, full of Diceras and Nerinea (as in Haute Saône), have been recently followed by him over the whole northern inclination of the Suabian Jura. ('Verhandlungen der Königl. Akad. der Wissenschaften zu Berlin.')

Von Dechen's opinion on this subject appears to coincide with that of Von Buch; and the researches of Count Munster and Goldfuss on the organic remains may be quoted in confirmation of the view that the German Jura, like that of the Swiss frontier, contains the equivalents, more or less developed, of the whole English oolitic series; and we are encouraged to hope that a careful comparison of the limestone ranges which border the Alps and extend into Dalmatia will determine, more exactly than we now know, the relation which they bear to the 'Jura formation' of the rest of Europe.

The determination of the geological epoch of the elevation of the Jura ranges to constitute dry land is important, especially in reference to two phenomena which are witnessed in these mountains, viz. the ossiferous caverns of Franconia, and the dispersion of erratic blocks from the High Alps. The opinion of John Hunter (Dr. Travers's *Oration to the College of Surgeons*, 1838), that the caverns of the district of Muggendorf were filled by bears which voluntarily retired thither, has been confirmed by subsequent researches. (Buckland, *Reliquiæ Diluvianæ;* and Von Meyer, *Palæologica*.) But the geological æra of their existence is perhaps subsequent to the whole tertiary period, while Von Buch's view of the origin of the Jurassic limestones seems to imply their prominence as islands in the antient European sea before the deposition of the chalk. If this opinion be well founded, the problem of the dispersion of the erratic blocks from the High Alps, which has so long perplexed geology, is still involved in undiminished difficulty. These blocks lie in vast abundance on the south-eastern slopes of the Jura, and ascend towards their summits, even to the height of 1000 or 2000 feet above the Aar and the Lake of Geneva, which now interpose their waters between the Jura and the mountains whence the blocks were drifted.

These blocks lie in such a manner that ordinarily those which came from a particular district are distinct from the others, and seem to have been brought by a distinct channel. Blocks from the Grisons have descended the valley of the Rhine; those found on the shores of the Lake of Zürich and in the drainage of the Limmat are derived from the mountains of Glarus; while in the valley of the Aar and on the slopes of the Jura lie fragments from the Bernese Alps. They occur in greatest abundance opposite the mouths of the great valleys which descend from the High Alps; at such points they have been drifted farthest up the slopes of the Jura, in some cases even to 1200 metres (1300 yards) above the sea. They exhibit few or no marks of rolling.

To account for these facts, numerous speculations have been proposed. De Luc imagined a projectile force to have displaced the blocks when the Alps were raised; Saussure, Escher, Von Buch, De Beaumont, &c. speak of the effects of water thrown into violent agitation (as some think by the elevation of the mountains); Dolomieu attributed the inequalities of surface, which render the physical explanation of the phenomena by the ordinary agencies of nature almost desperate, to operations subsequent to the scattering of the blocks; Venturi introduced the consideration of floating ice-rafts, since become popular; while others have attempted to master the difficulty of the problem by admitting great changes of level since the blocks were moved from their native sites.

According to this view, the erratic blocks of the Jura were accumulated round the Alps by the ordinary or extraordinary action of water-currents in antient Alpine valleys, on surfaces which were at a later period lifted to their present height by subterranean movements. (Brongniart, *Tableau des Terrains*.) [ERRATIC BLOCKS.]

JURA KALK, the German equivalent of the oolitic system of England.

JURISPRUDENCE. The Latin word *prudentia* (contracted from *providentia*) came, by a natural transition, to mean *knowledge* or *understanding*. 'Habebat (says Nepos, *Life of Cimon*, c. 2) magnam prudentiam tum juris civilis tum rei militaris:' hence persons skilled in the Roman law were called *juris prudentes*, or simply *prudentes;* in the same manner that they were called *consulti*, as well as *juris consulti*. (Haubold's *Lineamenta Instit. Juris Romani*, lib. iv., cap. 5; Hugo, *Geschichte des Römischen Rechts*, p. 458, ed. xi.) A large part of the Roman law was gradually adopted by the legislature and the judices from the writings of the jurists: the emperors moreover sometimes appointed persons whose opinions (or *responsa*) the judex was bound to follow. (*Dig.*, lib. i., tit. 2., No. 2, s. 5-7, 35-47; *Inst.*, lib. i., tit. 2, s. 8.) According to the acceptation of the term *prudens* or *juris prudens* in the Roman law, *juris prudentia* is sometimes limited to the dexterity of a practical lawyer in applying rules of law to individual cases; whence the technical use of the term *jurisprudence* in the French legal language for law founded on judicial decisions, or on the writings of jurists.

By *general jurisprudence* is properly meant the science or philosophy of positive law, as distinguished from *particular jurisprudence*, or the knowledge of the law of a determinate nation. 'General jurisprudence, or the philosophy of positive law, is not concerned directly with the science of legislation: it is concerned directly with principles and distinctions which are common to various systems of particular and positive law, and which each of those various systems inevitably involves, let it be worthy of praise or blame, or let it accord or not with an assumed measure or test.

General jurisprudence is concerned with law as it necessarily is, rather than with law as it ought to be; with law as it must be, be it good or bad, rather than with law as it must be, if it be good.' (Austin's *Outline of a Course of Lectures on General Jurisprudence*, p. 3.) For example, every system of positive law must involve such notions as sovereignty, legal right, legal duty, legal sanction, civil or criminal injury, the grounds of imputation or legal guilt, and of non-imputation or legal innocence, property, possession, &c., which therefore belong to the province of general jurisprudence. [LAW; LEGISLATION.]

A systematic treatise on general jurisprudence does not fall within the scope of this Cyclopædia. A detailed, precise, and lucid description of the province of general jurisprudence will be found in Mr. Austin's work on the subject (8vo., London, 1832), and the annexed outline of a course of lectures. (*Journal of Education*, No. 8, p. 285.) Bentham's 'Traités de Législation' also contain much valuable matter relating to this subject. A list of works on general jurisprudence may be seen in Krug's 'Philosophisches Lexicon,' in the article *Rechtslehre.*

JURY (in English law) is a term of art denoting an assembly of men authorized to inquire into or to determine facts, and bound in both cases by an oath to the faithful discharge of their duty. The etymological derivation of the term is obviously from *juro*, to swear, whence we find this institution called in forensic Latin *jurata*, and the persons composing it *jurati*; in French *les jurés*, and in English *the jury*. In English law, when the object is inquiry only, the tribunal is sometimes called an inquest or inquisition, as in the instance of a grand jury or coroner's inquest; but when facts are to be determined by it for judicial purposes, it is always styled a jury. When the trial by jury is spoken of in popular language at the present day, it signifies the determination of facts in the administration of civil or criminal justice by twelve men sworn to decide facts truly according to the evidence produced before them.

Inquiry into facts on behalf of the crown by means of juries was frequent in England long before the trial by jury was commonly used in courts of justice for judicial purposes. Thus we find, immediately after the Conquest, inquisitions *ad quod damnum* (which antiently took place in all grants by the crown, though now of more limited use): inquisitions *post mortem*, which were instituted on the death of the king's tenants, to ascertain of what lands they died seised; inquisitions of lunacy (*de lunatico inquirendo*); and several other inquests, which were called inquests of office, and took place where the crown was concerned in interest: all of these inquiries were made by means of juries of the neighbourhood, who were presumed to be necessarily conversant with the facts. So in England also in the reign of John, when the lands of the Normans were seised into the hands of the king, inquisitions by jury were executed in each county to ascertain their value and incidents. (See the forms of these inquests in Hardy's *Rotuli Normanniæ*, vol. i., p. 122.)

Besides these juries of inquiry (*inquisitoria jurata*), there were accusatory juries (*jurata delatoria*), who presented offences committed within their district or hundred to the king or his commissioned justices. These inquests were immediately connected with the administration of justice, their duty being to charge offenders, who, upon such accusation, were put upon their trial before judges, and were afterwards condemned or 'delivered' by them according to the result of the trial. Though the character, incidents, and duties of these accusatory juries in early times are involved in much obscurity, there is little doubt that they formed the origin of our present grand juries.

The number of persons composing juries of inquiry and accusatory juries was arbitrary, and might consist of more or occasionally of fewer than twelve men.

The third species of jury is the institution by which disputed facts are to be decided for judicial purposes in the administration of civil or criminal justice, and which is in modern times familiar to us under the denomination of *trial by jury*. Dr. Pettingall, in a Tract published in 1769, expresses a confident opinion that juries of this description are the same functionaries as the dicastæ (δικασταί) of the Athenians and the judices of the Romans, and maintains that our trial by jury was derived immediately from Rome, and ultimately from Greece. No doubt the similarity of several of the incidents enumerated in this curious tract are remarkable [JUDEX, JUDICIUM]; but it seems more probable that they are rather to be ascribed to the accidental resemblance of popular institutions for the administration of justice in different countries than to identity of origin. The precise time at which this species of trial originated in England has been the subject of much animated discussion; and in particular the question whether it was known to the Anglo-Saxons, or was introduced by the Conqueror, has been warmly debated. Coke and Spelman, among earlier legal antiquaries, and, in later times, Nicholson (*Preface* to Wilkins's *Anglo-Saxon Laws*, p. 9), Blackstone (*Commentaries*, book iii., c. 22), and Turner (*History of Anglo-Saxons*, vol. iv., book xi., cap. 9), maintain with much confidence the existence of this institution before the Conquest. On the other hand, Hickes (*Dissert. Epist.*, p. 34), Reeves (*History of the English Law*, vol. i., p. 24), and several other learned writers, contend that it was introduced by the Conqueror, or at least that it was derived from the Normans, and was not of Anglo-Saxon origin. The latter opinion is adopted by Sir Francis Palgrave, in his *History of the English Commonwealth*, vol. i., p. 243.

Without entering minutely into this controversy, it may be stated that the traces of the trial by jury, in the form in which it existed for several centuries after the Conquest, are more distinctly discernible in the antient customs of Normandy than in the few and scanty fragments of Anglo-Saxon laws which have descended to our time. The trial by 12 compurgators, which was of canonical origin and was known to the Anglo-Saxons and also to many foreign nations, resembled the trial by jury only in the number of persons sworn; and no conclusion can be drawn from this circumstance, as 12 was not only the common number throughout Europe for canonical and other purgations, but was the favourite number in every branch of the polity and jurisprudence of the Gothic nations; *Purget se duodecimâ manu vel duodecim sacramentalibus* was a common phrase. (See Spelman's *Gloss.*, tit. *Jurata*; also *Edinburgh Review*, vol. xxxi. p. 115.) For this reason Mr. Hallam justly observes (*Middle Ages*, vol. ii., p. 401) that in searching for the origin of trial by jury, 'we cannot rely for a moment upon any analogy which the mere number affords.' Besides this, the trial by compurgators under the name of Wager of Law continued to be the law of England until it was abolished, in 1833, by the statute 3 and 4 Will. IV., c. 42, s. 13, and is treated by all writers and noticed in judicial records ever since the Conquest as a totally different institution from the trial by jury. The trial *per sectatores* or *per pares* in the county court, which has sometimes been confounded with the trial by jury, was in truth a totally different tribunal. The sectatores or pares were, together with the sheriff or other president, judges of the court,—as are the suitors in the county courts at the present day; and it appears to have been the common course with the Gothic nations that twelve assessors should be present with the king or judge to decide judicial controversies. (Du Cange, *Gloss*., ad vocem *Pares*.) The *pares curiæ* resembled permanent assessors of the court, like the *scabini* mentioned in the early laws of France and Italy, much more nearly than sworn jurors indiscriminately selected, and performing a subordinate part to the judge. On the other hand, the incidents of the mode of trial prevalent in Normandy long before the Conquest correspond in a striking manner with those of our trial by jury as it existed for centuries afterwards. Thus in Normandy offenders were convicted or absolved by an inquest of good and lawful men summoned from the neighbourhood where the offence was surmised to have been committed. The law required that those were to be selected to serve on such inquest who were best informed of the truth of the matter; and friends, enemies, and near relatives of the accused were to be excluded. So also in the Norman Writ of Right, those were to be sworn as recognitors who were born and had even dwelt in the neighbourhood where the land in question lay, in order that it might be believed that they knew of the truth of the matter and would speak the truth respecting it. (*Grand Coustumier*, cap. 68, 69, 103.) These incidents, though unlike our present mode of trial (which, as will presently be shown, has entirely altered its character within the last four centuries), are nearly identical with the trial by jury as it is described first by Glanville and afterwards by Bracton, and correspond almost verbally with the form of the jury process, which has continued the same from very early times to the present day; by which the sheriff is commanded to return 'good and lawful men of the neighbourhood, by whom the truth of the matter may be better known, and who are not

akin to either party, to recognize upon their oaths, &c.' On the other hand (as Madox remarks, in his *History of the Exchequer*, p. 122), 'if we compare the laws of the Anglo-Saxon kings with the forms of law process collected by Glanville, they are as different from one another as the laws of two several nations.'

Though there are some traces of the trial by jury in the four reigns which immediately succeeded the Norman Conquest, it was not till a century afterwards, in the reign of Henry II., that this institution became fully established and was reduced to a regular system. Its introduction into frequent use at this period was probably owing to the law or ordinance for the trial by assize in pleas of land or real actions, made by Henry II. This law has not come down to our times, but it is fully described by Glanville (lib. ii. cap. 7), and the greater part of the treatise of that writer is occupied by an account of the practical machinery of the trial by twelve men which he warmly eulogises and represents as having been introduced in opposition to the unsatisfactory mode of trial by battle or duel. In the reign of Henry II. it appears also that a jury was sometimes used in matters of a criminal nature—the proceeding in such cases being noticed as an inquiry *per juratam patriæ vel vicineti*, or *per juramentum legalium hominum*. Thus in the 'Constitutions of Clarendon,' enacted in 1164, it is directed that 'if no person appeared to accuse an offender before the archdeacon, the sheriff should, if requested to do so by the bishop, cause twelve lawful men of the neighbourhood or of the township to be sworn, who might declare the truth according to their conscience.' These however were probably accusatory juries, similar to our grand inquests, and not juries employed for the actual trial or 'deliverance' of criminals, which do not seem to have been commonly used until a later period.

The law of Henry II. introduced the trial by assize or jury in real actions as a mode of deciding facts which the subject might claim as a matter of right. Glanville calls it 'a certain royal benefit conferred upon the people by the clemency of the sovereign with the advice of the nobility.' Accordingly we find in the *Rotuli Curiæ Regis* in the time of Richard I. and John, many instances of trials by jury being claimed by parties, though it appears from these curious records that at this period the trial by battle was still in frequent use. In the reign of John we first begin to trace the use of juries for the trial of criminal accusations. At first it seems to have been procured by the accused as a special favour from the crown, a fine, or some gift, or consideration being paid in order to purchase the privilege of a trial by a jury. Several instances of this kind will be found collected in the Notes and Illustrations to Palgrave's *Commonwealth of England*, vol. ii., p. 186. The payment of a fine took place also not unfrequently in civil cases where any variation from the regular course was required; see *Rotuli Curiæ Regis*, vol. i., pp. 354, 375; vol. ii.. pp. 72, 92, 97, 101, 114. It is quite clear, however, from Bracton and Fleta, that at the end of the thirteenth century the trial by jury in criminal cases had become usual, the form of the proceedings being given by them in detail. (See Bracton, p. 143.) Introduced originally as a matter of favour and indulgence, it gained ground with advancing civilization, gradually superseding the more antient and barbarous customs of battle, ordeal, and wager of law, until at length it became, both in civil and criminal cases, the ordinary mode of determining facts for judicial purposes.

It is right to notice the popular and remarkable error that the stipulation for the *judicium parium* in Magna Charta referred to the trial by jury. Sir Edward Coke in his commentary upon Magna Charta expressly distinguishes between the trial by peers and the trial by jury (2nd Inst. 48-9); but Blackstone says, 'The trial by jury is that trial by the peers of every Englishman, which, as the grand bulwark of his liberties, is secured to him by the Great Charter.' (*Commentaries*, vol. iv., p. 349.) This is confounding two distinct modes of trial. The *judicium parium* was the feudal mode of trial, where the *pares* or *convassalli ejusdem domini* sat as judges or assessors with the lord of the fee to decide controversies arising between individual *pares*. It was a phrase perfectly understood at the period of Magna Charta, and the mode of trial had been in use long before in France and all parts of Europe where feuds prevailed. (Du Cange, *Gloss.*, ad vocem *Pares*.) It was essentially different from the trial by jury, which could never be accurately called *judicium parium*. We read frequently in the records of those times (and even in Magna Charta itself), of *juratores*, of *veredictum* or *juramentum legalium hominum*, and *jurata vicineti* or *patriæ*, all of which expressions refer to a jury; but not a single instance can be found in any charter, or in any antient treatise or judicial record, in which the jury are called *pares*, or their verdict *judicium*. (Reeves's *History of the Law*, vol. i., p. 249.) In the records of the 'Curia Regis' in the first year of John's reign, among numerous entries of *Ponit se super juratam vicineti* or *patriæ*, are also entries of *Ponit se super pares suos de eodem feodo*, plainly indicating a distinction between the two modes of trial. (*Rotuli Curiæ Regis*, vol. ii., p. 90.)

Until about the reign of Henry VI. the trial by jury was to all intents and purposes a trial by witnesses. The present form of the juror's oath is that they shall 'give a true verdict, *according to the evidence*.' At what precise time this form was introduced is uncertain; but for several centuries after the Conquest, the jurors both in civil and criminal cases were sworn merely *to speak the truth*. (Glanville, lib. ii., cap. 17; Bracton, lib. iii., cap. 22; lib. iv., p. 287, 291; Britton, p. 135.) Hence their decision was accurately termed *veredictum*, or verdict; whereas the phrase 'true verdict' in the modern oath is not only a pleonasm, but is etymologically incorrect, and misdescribes the office of a juror at the present day. Many other incidents of the trial by jury, as recorded in antient treatises, conclusively show that the jury were merely witnesses. They were brought from the neighbourhood where the disputed fact was suggested to have occurred, because, as the form of the jury process says, they were the persons 'by whom the truth of the matter might be better known;' no doubt upon the principle that *Vicini vicinorum præsumuntur scire*. Again, if the jurors returned by the sheriff in the first instance declared in open court that they knew nothing of the matter in question, others were summoned who were better acquainted with it. (Glanville, lib. ii., cap. 17.) They might be excepted against by the parties upon the same grounds as witnesses in the Court Christian. They were punished for perjury if they gave a wilful false verdict; and for *crassa ignorantia* if they declared a falsehood or hesitated about their verdict upon a matter of notoriety, which all of the country (*de patriâ*) might and ought to have known. (Bracton, p. 290.) And antient authors solemnly admonish judges to 'take good heed in inquisitions touching life and limb, that they diligently examine the jurors from what source they obtain their knowledge, lest peradventure by their negligence in this respect Barabbas should be released and Jesus be crucified.' (Bracton, lib. iii., cap 21; Fleta, lib. i., cap. 34.) It is also remarkable, as one of the numerous circumstances which show the character of the jury in the earlier periods of the history of the institution, that though all other kinds of murder might be tried by a jury, murder by poison was excepted, 'because,' say the antient writers, 'the crime is so secret that it cannot be the subject of knowledge by the country.' (Bracton, lib. iii., cap. 18; Fleta, lib. i, cap. 31.)

The original principle and character of the trial by jury in criminal cases in Scotland appear to have been the same as in England. The following extract is taken from a curious paper delivered to the Speaker of the House of Commons, and recorded on the Journals at the date 4th June, 1607. (*Comm. Journ.*, vol. i., p. 378.) 'In Scotland criminal causes are not governed by the civil law; but *ordanes** and juries pass upon life and death, very near according to the law here (in England). Which jury being chosen out of the Four Halfs about (as the Scottish law terms it), which is to say, out of all places round about that are nearest to that part where the fact was committed, the law doth presume that the jury may the better discern the truth of the fact by their own knowledge; and therefore they are not bound to examine any witnesses, except out of their own disposition they shall please to examine them in favour of the party persuer; which is likewise very seldom or almost never used. It is of truth that the judge may either privately beforehand examine such witnesses as either the party persuer will offer unto him, or such others as in his own judgment he thinks may best inform him of the truth; and then when the jury is publicly called and admitted, he will cause these depositions to be produced and read; and likewise if the party persuer desire any witness there present to be examined, he will publicly do it in presence of the jury and both parties.' It will be observed, that the

* This word is so printed in the Journals, but it is probably a mistake for some other word.

mode of commencing the introduction of evidence to juries as described in this document bears a strong resemblance to the growth of the proceeding in England.

The earliest traces of the examination of witnesses or of evidence being laid before juries in England, which formed the commencement of a total change in their character, occur in the reign of Henry VI. The change was not effected suddenly, or by any particular act of parliament, but was introduced by slow degrees as population increased, and the habits and manners of society underwent alteration; and though distinctly discernible in the reign of Henry VI., was not completely effected before the times of Edward VI. and Mary. Fortescue, in the 26th chapter of his work 'De Laudibus Legum Angliæ,' written at the end of the reign of Henry VI., and about the year 1470, expressly mentions that witnesses were examined and sworn before the jury; but he calls the jury indiscriminately *testes* and *juratores*, and makes frequent allusions to their character as witnesses. Shortly after Fortescue's time, namely, in the year 1498, there is a reported case between the bishop of Norwich and the earl of Kent (*Year Book*, 14 Henry VII.), in which a jury had been separated by a tempest 'while the parties were showing their evidence:' and one question raised for the opinion of the court was, whether, when the jury came together again, they were competent to proceed with the case and to give a verdict. The objection pressed was that the jury had separated before the evidence was given; to which it was answered that 'the giving the evidence was wholly immaterial, and made the matter neither better nor worse; that evidence was only given in order to inform the consciences of the jury respecting the rights of the parties; but that if neither party choose to give evidence, still the jury would be bound to deliver a verdict.'

About the same period, that is, in the reign of Henry VII., it appears from records printed in Rastell's Entries that demurrers to evidence were an acknowledged form of proceeding, which shows that at that time evidence of some kind was given, and consequently that the character of the jury had been in some degree changed from that of *witnesses* to that of *judges* of facts upon testimony. The proofs mentioned in these records are called *evidentia*; and it is most probable that at first the only evidence given consisted of deeds, writings, and of depositions of absent witnesses taken before the justices of the peace or other magistrates, and that oral testimony was not common until a later period. The entire absence of all mention of evidence or witnesses, as contradistinguished from jurors, in treatises, reports, records, or statutes, previously to the sixteenth century, strongly corroborates the fact of the early character of the trial by jury. There is no trace of any rules of evidence, nor of any positive law compelling the attendance of witnesses, or punishing them for false testimony or non-attendance, nor of the existence of any process against them before the stat. 5 Eliz., c. 9 (1562). In the case of Summers *v.* Mosely, reported in 2 Crompton and Meeson, p. 485, Mr. Baron Bayley says that he had been unable to find any precedents of the common *Subpœna ad testificandum* of an earlier date than the reign of Elizabeth, and expresses a conjecture that this process may have originated with the above-mentioned statute. The *Subpœna ad testificandum* does not appear in the registers of Writs and Process until the reign of James I. (West's *Symboleography*.) Witnesses were examined orally upon the trial of Sir Thomas More, in the reign of Henry VIII.; but the reported state trials in the reigns of Edward VI. and Mary show that the practice in that respect was then by no means settled. In the reign of Elizabeth however there is abundant proof, from Sir Thomas Smith's 'Commonwealth of England,' and other authorities, that oral testimony was used without reserve (except in state prosecutions) both in civil and criminal trials; and consequently it cannot be doubted that about the middle of the sixteenth century the trial by jury had fully assumed the character in which we are now familiar with it, namely, an institution deciding facts for judicial purposes by means of testimony or evidence produced before the jury.

This view of the original character and office of the jury seems to account for the practice of fining or otherwise punishing juries by the court when they gave an unsatisfactory verdict, a practice which was partially continued, though not without remonstrance by legal authorities, after the nature of the institution had been changed. If juries, who re merely witnesses sent for to inform the court of facts which they were presumed certainly to know, returned a wilfully false verdict, they were guilty of a contempt of justice, and might properly be punished; but when their character was changed, and their verdict depended not on their own knowledge of the facts, but upon the impressions produced on their minds by the evidence, such a course of summary punishment became intolerable injustice; and though occasionally practised in the sixteenth century, was declared to be illegal soon after the Restoration by the celebrated judgment in Bushell's case, reported in Vaughan's Reports, p. 135.

The juries now in use in England in the ordinary courts of justice are grand juries, petty or common juries, and special juries. Grand juries are exclusively incident to courts of criminal jurisdiction; their office is to examine into charges of crimes brought to them at assizes or sessions, and if satisfied that they are true, or at least that they deserve more particular examination, to return a bill of indictment against the accused, upon which he is afterwards tried by the petty jury. A grand jury must consist of 12 at the least, but in practice a greater number usually serve, and 12 must always concur in finding every indictment. No further qualification is required for grand jurors (except in the case of grand jurors at the sessions of the peace, provided for by the recent Jury Act) than that they should be freeholders, though to what amount is uncertain; or freemen, lawful liege subjects, and not aliens or outlaws. (Hawkins's *Pleas of the Crown*, chap. 25, sect. 16.)

Until the end of the thirteenth century the only qualification required for petty or common juries, for the trial of issues in criminal or civil courts, was that they should be 'free and awful men;' *freemen*, as holding by free services or free burgesses in towns; and *lawful* men, that is, persons not outlawed, aliens, or minors, but entitled to the full privileges of the law of England. By the statute of Westminster 2, passed in the thirteenth year of Edward I. (1296), it was enacted that no man should be put on juries who had not some freehold of the value of 20*s*. a year within the county, or 40*s*. without it; and this qualification was raised to 40*s*. in counties by the stat. 21 Edward I. The object of these statutes was to protect poor persons from being oppressed and injured by being summoned on juries, and also to obviate the evil of the non-attendance of jurors, which frequently occurred from their inability to leave their agricultural or handicraft occupations. The stat. 2 Henry V. however was expressly intended to secure the intelligence and responsibility of jurors by requiring a property qualification. With this view it enacted that no person should be a juror in capital trials, nor in any real actions, or personal actions where the debt or damages declared for amounted to 40 marks, unless he had lands of the yearly value of 40*s*.; and if he had not this qualification he might be challenged by either party. This continued to be the qualification of common jurors until the passing of the late statute 6 George IV., c. 50, which repealed all former statutes upon this subject, and entirely remodelled the law respecting juries. By this statute 'every man (with certain specified exceptions) between the ages of twenty-one years and sixty years who has within the county in which he resides 10*l*. a year in freehold lands or rents, or 20*l*. a year in leaseholds for unexpired terms of at least twenty-one years, or who, being a householder, is rated to the poor-rate in Middlesex on a value of not less than of 30*l*., and in any other county of not less than 20*l*., or who occupies a house containing not less than fifteen windows, is qualified and liable to serve on juries in the superior courts at Westminster and the courts of the counties palatine for the trial of issues to be tried in the county where he resides, and also to serve on grand juries at the sessions of the peace, and on petty juries, for the trial of issues triable at such sessions in the county in which he resides.' The exceptions are:—peers, judges of the superior courts, clergymen, Roman Catholic priests, dissenting ministers following no secular employment but that of a schoolmaster, serjeants and barristers at law, and doctors and advocates of the civil law actually practising; attorneys, solicitors, and proctors actually practising; officers of courts actually exercising the duties of their respective offices; coroners, gaolers, and keepers of houses of correction; members and licentiates of the college of physicians actually practising; surgeons, being members of one of the royal colleges of surgeons in London, Edinburgh, or Dublin, and actually practising; apothecaries certificated by the Apo-

thecaries' Company and actually practising; officers in her majesty's navy or army on full pay; pilots licensed by the Trinity House; masters of vessels in the buoy and light service; pilots licensed by the lord-warden of the cinque-ports, or under any act of parliament or charter; household servants of the sovereign; officers of customs and excise; sheriffs' officers, high constables, and parish clerks.

Lists of all persons qualified to be jurors are made out by the churchwardens and overseers of each parish, and fixed on the church door for the first three Sundays in September in each year; these are afterwards allowed at a petty sessions and then delivered to the high constable, who returns them to the next quarter-sessions for the county. The clerk of the peace then arranges the lists in a book, which is called the 'Jurors' Book' for the ensuing year, and afterwards delivers it to the sheriff. From this book the names of the jurors are returned in panels to the different courts.

Special juries are composed of such persons as are described in the 'Jurors' Book' as esquires, and persons of higher degree, or as bankers or merchants; and it is the duty of the sheriff to make a distinct list of such persons, which is called the 'Special Jurors' List.' When a special jury is ordered by any of the courts, which must always be the result of a special application of one of the parties, 48 names are taken by ballot from this list in the manner particularly described in the statute, which are afterwards reduced to 24 by means of each party striking out 12; and the first 12 of these 24 who answer to their names in court are the special jury for the trial of the cause.

The legitimate mode of objecting to a jury by the parties is by challenge, though in modern practice this course is seldom resorted to, having yielded to the more convenient usage of privately suggesting the objection to the officer who calls the jury in court; upon which the name objected to is passed over as a matter of course without discussion. This practice, though a far less troublesome and obnoxious mode of effecting the object of obtaining a jury indifferent between the parties than a formal challenge, is strictly speaking irregular, and being considered to take place by consent, and as a matter of favour, cannot be insisted upon as a right. Challenges are of two kinds: challenges to the *array*, and challenges to the *polls*. The challenge to the array is an objection to the whole panel or list of jurors returned for some partiality or default in the sheriff or the under-sheriff by whom it has been *arrayed*. Challenges to the polls are objections to particular jurors, either on the ground of incompetency (as if they be aliens, or of insufficient qualification within the provisions of the Jury Act, 6 Geo. IV., cap. 50), or of bias or partiality, or of infamy as having been convicted of some crime which the law deems infamous. Upon these challenges the cause of objection must in each case be expressly shown to the court; but in trials for capital offences the accused is entitled to challenge *peremptorily* (that is, without giving any reason) thirty-five jurors. The king however, as nominal prosecutor, has no right of peremptory challenge, though he is not compelled to show his cause of challenge until the panel is gone through, and unless a full jury cannot be formed without the person objected to.

The trial by jury, originally introduced into the law of France in criminal cases by the National Assembly, was retained in the French code. An account of the proceeding and of the qualifications and formation of the jury will be found in the *Code d'Instruction Criminelle*, livre ii., tit. 2, chap. iv. and v. See also *Edinburgh Review*, vol. xvii., p. 97, and the article CODES, LES CINQ. It has often been remarked as a singular fact that the institution which in England has been highly prized as a security to the subject against the crown, should have been preserved in France by a despotic monarch, in the zenith of his power, and certainly not disposed to enlarge popular authority. Of late years the advantage of the trial by jury has been frequently the subject of debate among German and French jurists, and in particular the propriety of its introduction has been discussed in the various commissions issued with a view to reforming the laws of several of the German States. [FEUERBACH.] The latest discussion of the latter kind related to the proposal to introduce the jury trial in the Canton de Vaud. The report of a commission issued by the state to inquire into this subject in 1836, against the jury, signed by a majority of the commissioners, and also a protest or counter-report containing the reasons of the only commissioner who dissented from the report, have been published. Upon the subsequent discussion of the proposition in the Grand Council, in December, 1836, the introduction of the trial by jury in the canton was negatived by a majority of 90 to 40 voices.

Anciently in Scotland all offences were tried by juries; at present all prosecutions of a higher nature must proceed by an assize or jury of 15 men, who determine their verdict by a majority of voices. (See Erskine's *Principles of the Law of Scotland*, book iv., tit. 4.) In the course of the improvements of the court of session projected and partly executed in the years 1808 and 1809, an attempt was made to introduce the trial by jury into civil proceedings in Scotland; but great and general opposition was made to it in that country, and the proposition was not at that time carried into effect. But in the year 1815 a statute (55 Geo. III., c. 42) was passed, though then still much opposed in Scotland, which established a jury court, not as a separate and independent tribunal, but as subsidiary to the court of session, for the trial of particular questions of fact to be remitted for trial by the judges of the court of session at their discretion. In order to meet a conscientious difficulty much insisted upon in petitions from Scotland against this measure, namely, that it would be often impossible for a jury to give a unanimous verdict unless some of the members violated their oaths, it was provided by the act that if the jury are not unanimous in 12 hours, they shall be discharged, and a new trial granted. The judges of this court, called the 'Lords Commissioners of the Jury Court in Civil Cases,' are appointed by commission, and consist of a chief judge and two other judges. The stat. 59 Geo. III., c. 35, which recites that the introduction of the trial by jury in civil cases by the former act had been found beneficial, enacts a variety of improvements in the machinery of the jury courts, and makes them a permanent part of the judicial establishment of Scotland. By the stat. 2 Geo. IV., and 1 Will. IV., c. 69, the jury court as a separate tribunal was abolished, and the trial by jury was united with the ordinary administration of justice in the court of session.

JUSSIEU, ANTOINE LAURENT DE, an eminent French botanist, was born at Lyon in 1748, and arrived in Paris in 1765 for the purpose of completing his education as a medical practitioner. He was then placed under the care of his uncle Bernard de Jussieu, at that time one of the demonstrators of botany in the Jardin du Roi, a man possessing a profound knowledge of plants, and who probably gave his nephew the first interest in that science which he subsequently illustrated with so much success. In the year 1770, his medical studies having been completed, he took the degree of doctor of medicine, on which occasion the title of his thesis was, *An œconomiam vitalem inter et vegetalem analogia*, a subject which sufficiently marks the turn his studies had already taken. In the same year he was nominated botanical demonstrator in the Jardin du Roi, as a substitute for Lemonnier, whose duties as chief physician to the king prevented his executing that office in person. Thus at the early age of twenty-two years Jussieu found himself under the necessity of undertaking the duty of teaching students the essential characters of the plants cultivated in the Paris Garden, a task for which experience in details and practical knowledge were required, rather than that general acquaintance with botany which a young man just released from his medical curriculum might be expected to possess. This obliged him to study one day the subjects to be demonstrated the next, and to occupy himself incessantly with acquiring a correct practical acquaintance with plants. At that time the collection of plants in the Jardin du Roi was arranged according to the method of Tournefort; but shortly afterwards it became necessary to rearrange it. Of this opportunity Jussieu took advantage; he drew up a memoir upon a new method of arrangement, which was read before the Academy of Sciences, and afterwards carried into effect in the Garden. The idea of this method was undoubtedly taken from a classification of the plants in the Royal Garden of Trianon, executed under the direction of his uncle; but it was different in much of the details, and was prepared without consultation with Bernard de Jussieu, who in fact was at that time old, nearly blind, ill, and incapable of taking part in any mental exertion. Previously to this, young De Jussieu had studied the natural order Ranunculaceæ with so much attention, that he had made it the subject of a communication to the Academy of Sciences, in whose Transactions it was printed. In after-years he used to say that it was the composition of

this memoir which had opened his eyes to the real principles of botanical classification and made him a botanist. It is here that is found the first distinct trace of those clear ideas concerning the relative importance and subordination of characters which the author subsequently applied to the whole vegetable kingdom. In reality there is no natural order of plants altogether so well suited for this purpose as that which happened to be selected.

From this time, that is, from the year 1774 up to 1789, De Jussieu was constantly occupied in demonstrating to his class of botany, and as his new method was thus brought perpetually before him, with all its advantages and disadvantages in practice, he was able to alter and improve it yearly. The distinctions of genera, their mutual relation, the natural sequence of his orders, and in addition all that was written by other botanists during this period, became so familiar to him, that his son records his having actually commenced his great work, the 'Genera Plantarum,' in 1788, without having prepared more than the commencement of the manuscript; and he adds, that he was seldom, during the printing, above two sheets in advance of the compositors; a very remarkable circumstance, if the extreme attention to clearness and arrangement conspicuous in this work are borne in mind. It is however always to be remembered, that in those days botany was not what it now is; Jussieu enumerated only 2700 genera, while one, not of the latest general works, includes between 7000 and 8000.

This extraordinary work made its way slowly. At the time of its appearance the greater part of botanists were full of zeal and prejudice in favour of the sexual system of Linnæus; an idea prevailed that botany was merely the art of distinguishing one thing from another; and moreover the political state of Europe was most unfavourable to scientific investigations. As tranquillity was restored in France, the work of Jussieu began to be studied, and being studied it soon became the text-book of all the botanists of reputation in that country. But in the other nations of Europe it was otherwise. In England, when Dr. Robert Brown published his 'Prodromus Floræ Novæ Hollandiæ,' in 1810, upon the system of Jussieu, there probably were not more than two other botanists in this country who could understand or make use of it; and it was not till after the year 1820 that it became much known among us.

In his 'Genera Plantarum,' Jussieu divided the vegetable kingdom into classes, subclasses, orders, and genera, not according to certain arbitrary distinctions, but by taking into consideration all the circumstances which he was acquainted with in their manner of growth and degree of development. Those which he regarded as the least perfectly organized species he stationed at the one end of his system, and, proceeding upon the principle of continually grouping together those plants which resemble each other more than they resemble anything else, he gradually arrived at the highest forms of vegetable life through a long series of intermediate gradations. In determining the relative dignity of his orders, he assumed that those species are least perfectly organized which have no cotyledon or rudimentary leaf in their embryo; that next in degree, but higher than these, are such as have one cotyledon; and that highest of all are those whose seeds have two cotyledons: hence his classes *Acotyledons*, *Monocotyledons*, and *Dicotyledons*. In arriving at this conclusion he was justified by the fact that to the highest class belong the lofty trees of the forest, with all their intricate apparatus of trunks, and arms, and branches; to the middle the simple-stemmed palms, lilies, and grasses; and to the lowest such forms of vegetation as fungi, lichens, and sea-weeds.

In determining the subordination of the genera assembled under each of these classes Jussieu was influenced by other considerations. He regarded those dicotyledonous genera which have no corolla as lower than such as possess that organ, and among those which have it the adhesion of the parts of the corolla into a tube was looked upon as an indication of a structure inferior to the total separation of the petals: this gave him for his great dicotyledonous class the subclasses *Apetalæ*, *Monopetalæ*, and *Polypetalæ*. In addition to which he formed another subclass, called *Diclines irregulares*, out of such dicotyledonous plants as have the sexes separated, which he considered an irregularity of organization. As a last method of division Jussieu applied to Monocotyledons and all the subclasses of Dicotyledons a principle of analysis dependent upon the situation of the stamens, calling them *hypogynous* if the stamens originate clear of both calyx and ovary; *perigynous* if they grow from the calyx or corolla; and *epigynous* if their apparent origin is in the apex of the ovary. There seems to have been no other reason for this than that such a 'triplex staminis situs' was found to exist. The result of all these distinctions was the following scheme, under which were arranged all the natural orders known to the author:—

'Index Methodi
Ordines Naturales complectentis.

				Class
Acotyledones				1
Monocotyledones	Stamina hypogyna			2
	„ perigyna			3
	„ epigyna			4
Dicotyledones.	Apetalæ	Stamina epigyna		5
		„ perigyna		6
		„ hypogyna		7
	Monopetalæ	Corolla hypogyna		8
		„ perigyna		9
		„ epigyna	Antheris connatis	10
			Antheris distinctis	11
	Polypetalæ	Stamina epigyna		12
		„ hypogyna		13
		„ perigyna		14
	Diclines irregulares			15

In the state of science when this system was promulgated its excellence was most remarkable, nor is it certain even now in what way it can be best improved. Its faults are the artificial nature of all the divisions except those which are primary, the difficulty in many cases of determining to which of them a given plant belongs, and the numerous exceptions to which they are all subject, which may be owing to their being mere structural and not physiological distinctions. They have accordingly been much criticised, especially of late years, and every original writer attempts to improve them, with various success. But to use the words of his son, to whose sentiments it is impossible for any botanist to refuse his assent, 'What is it that is most admired in this work? not so much the systematical key, which has been so often attacked and abandoned by modern writers, as the admirable sagacity which regulated all the details. It is the neatness of the characters, the happy employment of such as had been previously neglected, and the correct estimate of their value, the prodigality with which notes full of deep knowledge and fruitful in new ideas are dispersed throughout the work, the endless questions and doubts, which show how much the author had meditated upon his subject, and that he was among the first to regret the sacrifices he was compelled to make to the necessity of a systematical arrangement; and finally, that instinct, so true to natural affinities, which so often made him suspect the truth when he could not establish it.'

No doubt Jussieu was largely indebted to our countryman Ray, whose name however does not appear among his introductory remarks; no doubt he was also assisted most essentially by Tournefort, Linnæus, and other systematical writers; but we are not on that account to withhold from him one particle of that merit which his countrymen eagerly claim for him. Ray could not apply his own principles; Tournefort and Linnæus were mere system-makers, who did not understand the principles of philosophical classification; but Jussieu had the philosophy of the one, the systematical abilities of the others, and the peculiar skill of combining them into a consistent whole. His 'Genera Plantarum' is now obsolete, but the recent publication of a new edition of his beautiful 'Introductio in Historiam Plantarum,' with which the work was prefaced, shows that to the last day of his existence Jussieu preserved that brilliant combination of sound philosophical principles with a profound knowledge of facts which has placed him so far above all his countrymen as a botanist.

In 1779, when the 'Genera Plantarum' was published, the political state of France, which put an end to peaceful occupations and turned the public from all thoughts of botany, disturbed the tranquil tenor of the course of Jussieu, and compelled him to mingle in the busy scenes of public life. In 1790 he was named member of the municipality of Paris, and in this character was charged with the direction of the hospitals and charities of that city, which he continued to exercise till 1792. In 1793 the Jardin du Roi was re-or-

ganized under the new name of Jardin des Plantes; all the persons charged with the duty of public instruction were elevated to the rank of professors, and De Jussieu, who had been previously botanical demonstrator, became professor of rural botany. He afterwards became director and treasurer of the Museum of Natural History, and recommenced, in 1802, his botanical writings, chiefly in the form of memoirs upon his own natural orders of plants. These, amounting in number to fifteen, were continued in the 'Annales du Museum' till 1820, after which time De Jussieu became dead to science. He was then seventy-two, with a sight so feeble that it might almost have been called blindness; and he was no longer able to do more than profit by the observations of others. Nevertheless he employed himself between his eighty-third and eighty-eighth year in dictating a new edition of his 'Introductio in Historiam Plantarum.' This work has been published since his death; it is written in elegant Latin, and is a remarkable proof of the vigour of his intellect even at this advanced age. He appears to have been much loved by his family and greatly respected by his friends. His amenity of character was such that he was never in any one of his writings betrayed into a single word of harshness towards his contemporaries. He died, after a short illness, on the 15th of September, 1836, and left behind him a son, Adrien, his successor in his chair of botany, and the inheritor of the virtue and talents of his father.

JUSTICE CLERK OF SCOTLAND. This name properly designated the clerk of court of the chief justice, or lord justiciar, of Scotland; and originally there were as many justice clerks as there were justiciars, that is to say, one for Galloway, one for Lothian, or the territory of the Scots king south of the Forth, and one for Scotland then strictly so called, or the territory north of the Forth.

The same circumstances also which reduced the number of justiciars to one justice-general for the whole realm, reduced likewise the number of justice clerks. The calamitous affair of Flodden however, to which we especially refer, had a further effect on the latter; for by the fall of Lawson and Henryson on that fatal field, the offices of both king's advocate and justice clerk became vacant at one time, and this at a period when perhaps few remained capable of either. Wishart of Pittarrow was appointed to both places, and in his time a deputy was first constituted, to act as clerk to the justice court. This was the first step in the singular rise of the justice clerk from the table to the bench of the Court of Justiciary.

At the institution of the Court of Session in 1532, the justice clerk was made one of the judges. This will not surprise us when we consider the constitution of that court. It was essentially an ecclesiastical tribunal, and, agreeably to the practice of such, deliberated in secret with shut doors. It was necessary therefore for the security of the crown that some of the crown officers should be continually present. The justice clerk was one of these: he was public prosecutor on behalf of the crown. The king's treasurer was another; and accordingly both these were lords of session. For the same reason the king's advocate was made a lord of session; and when, from there being no vacancy, or otherwise, such appointment did not or could not take place, these officers had special writs from the crown authorising them to remain in court during its deliberations.

A further rise of official dignity took place: for it having become usual to appoint certain lords of session as assessors or assistant judges to the lord justice-general, the justice clerk began in the early part of the seventeenth century to be appointed to that duty; and about the middle of the same century he had acquired the style of 'lord justice clerk.' In ten years afterwards the privy council met and passed an act, declaring the justice clerk a constituent part of the justice court; and in the act of parliament 1672, c. 16, he was made the president of the Court of Justiciary, to preside in absence of the justice-general. His rise in the Court of Session followed; for in 1766, when Miller, afterwards Sir Thomas Miller of Glenlee, took his seat on the bench, it was, by desire of the court, on the right of the lord president; to which latter office he himself afterwards rose, being the first justice clerk so promoted. And in 1811, when the Court of Session was, by 48 Geo. III., c. 151, divided into two chambers, the lord justice clerk was made *ex officio* president of the second division, where the individual then appointed still remains. His salary is 2000*l.*, besides an equal sum as a lord of session. In the end of the fourteenth century it was 10*l.* Scots, or 16*s.* 8*d.* sterling.

With respect to the *justice clerk depute*, that officer was long so termed; but at length, when the justice clerk acquired the style of lord, and was declared a constituent part of the Court of Justiciary, his *depute* came to be termed 'the principal clerk of justiciary,' and this becoming a sinecure, he got himself a 'depute' about the middle of last century, and the second depute about thirty years ago an 'assistant;' all of whom continue to this day, and are in the gift of the lord justice clerk. It is not a little remarkable, that on both occasions when these changes took place, there took place also not a diminution, as we might expect, but a duplication of the salary; that of the first depute being raised in 1764 from 100*l.* to 200*l.*, and that of the second depute, in 1795, from 80*l.* to 150*l.* The present principal clerk of justiciary, so called, is the justice clerk's son; and his substitute, or the second depute clerk, is the justice clerk's Court of Session clerk.

Besides these there are three other justice clerk deputes, and his appointees. They are commonly called the 'circuit clerks,' being his deputies to the three circuits of the Court of Justiciary. They had their origin in the act 1587, c. 82, which directed such circuits to be made, in place of the former practice of the justiciar passing through the realm from shire to shire successively.

JUSTICES OF THE PEACE are persons appointed to keep the peace within certain prescribed limits, with authority to act judicially in criminal causes, and in some of a civil nature arising within those limits, and also to do certain other things in which they act not judicially but ministerially, *i.e.* as servants of the crown performing official acts in respect of which they are entrusted with no judicial discretion. The authority of justices of the peace is derived from the king's prerogative of making courts for the administration of the law, or created by different statutes; their duties are expressed in the royal commission appointing them to the office, or are prescribed by those statutes.

Before the reign of Edward III. there were in every county conservators of the peace, whose duty it was to afford protection against illegal force and violence. These conservators were chosen by the freeholders assembled in the county court under the king's writ.

The lord chancellor, the judges of the king's bench, and every sheriff and coroner, were conservators, and are now justices, of the peace, by virtue of their office; and some lands are holden under the service annexed to the tenure of such lands of being conservators of the peace, or of providing fit persons to perform the duties of that office. High and petty constables are also by virtue of their offices conservators of the peace. The authority of conservators of the peace at the common law was the same as that now exercised by constables within their respective townships; and their duty consisted in acting themselves, and commanding the assistance of others, in arresting and quieting those who in their presence and within the limits of their jurisdiction went about to break the peace.

The following account is generally given of the origin of the present justices of the peace. Upon the compulsory resignation of Edward II., Edward III., or rather his mother Isabella, in his name, sent writs to the different sheriffs, stating that his accession had taken place with his father's assent, and commanding that the peace should be kept on pain of disinheritance and loss of life and limb. Within a few weeks from this time it was ordained, by 1 Edward III. c. 16, that for the better keeping and maintaining of the peace in every county good and lawful men who were not maintainers of barretry (malveiz barrets) should be assigned to keep the peace. The mode in which these new keepers of the peace were to be assigned was construed to be by the king's commission; and this ordinance had the double effect of transferring the appointment from the people to the crown, and of laying a foundation for the gradual accession of those powers which are now exercised by justices of the peace.

By 12 Richard II., c. 10, the wages of justices of the peace are fixed at four shillings per day of sessions, and two shillings for their clerks, payable out of the fines and amerciaments at such sessions; but these wages, like those of members of parliament, have long ceased to be received.

Justices of the peace are appointed either by act of parliament, by royal charter (in the case of justices in boroughs not within the Municipal Corporation Act the charter usually appointing certain municipal officers to be justices, and prescribing the manner in which vacancies in the offices are

to be filled up), or by a commission from the crown under the statute of 1 Edward III. The form of the commission of the peace has from time to time been altered, and the authority of the justices enlarged. As now framed it consists of two distinct parts, and contains two separate assignments or grants of authority. Of these the former gives to any one or more justices not only all the power relating to the maintenance of the peace which was possessed by the conservators at common law, but also all the additional authority mentioned in the statutes. The latter assignment defines the power of justices when the whole body, or such of them as choose to attend, act together in general sessions. [SESSIONS.]

The former part of the commission is as follows:—'Victoria, &c., to AB, CD, EF, &c., greeting: Know ye that We have assigned you jointly and severally, and every one of you, Our justices to keep Our peace in Our county of Z, and to keep and cause to be kept all ordinances and statutes for the good of the peace and for the preservation of the same, and for the quiet rule and government of Our people made, in all and singular their articles in Our said county, as well within liberties as without, according to the force, form, and effect of the same, and to chastise and punish all persons that offend against the form of those ordinances or statutes, or any one of them, in the aforesaid county, as it ought to be done according to the form of those ordinances and statutes; and to cause to come before you or any of you all those who to any one or more of Our people, concerning their bodies or firing their houses, have used threats, to find sufficient security for the peace or their good behaviour towards Us and Our people, and if they shall refuse to find such security, then them in Our prisons, until they shall find such security, to cause to be safely kept.'

By 5 Geo. II., c. 18, no attorney, solicitor, or proctor shall be a justice of the peace for any county whilst he continues in practice. By 18 Geo. II., c. 20, no person shall be capable of acting as a justice of the peace for any county, riding, or division, within England or Wales, who shall not have, in law or equity, to and for his own use and benefit, in possession a freehold, copyhold, or customary estate for life, or for some greater estate, or an estate for some long term of years determinable upon life or lives, or for a certain term originally created for twenty-one years or more, in lands, tenements, or hereditaments in England or Wales, of the clear yearly value of 100*l.* over and above all incumbrances affecting, and all rents and charges payable out of or in respect of the same, or who shall not be seised of or entitled to, in law or equity, to and for his own use and benefit, the immediate reversion or remainder of and in lands, tenements, and hereditaments, leased for one, two, or three lives, or for any term of years determinable on lives upon reserved rents, and which are of the yearly value of 300*l.*, and who shall not have taken and subscribed an oath stating the nature of the qualifying estate. The third section of this statute imposes a penalty of 100*l.* upon those who act without having taken and subscribed the oath, and for acting without being qualified. The statute however excepts from these provisions certain official persons, &c. A justice of the peace cannot legally act after he has ceased to be qualified; but it is not necessary that he should continue to retain the same qualification, nor will the absence of a qualification render his acts absolutely void.

Justices appointed by act of parliament or by the king's charter are not removable except for misconduct, but the authority of a justice appointed by the king's commission may be determined at the pleasure of the crown, either directly by writ under the great seal, or impliedly, by making out a new commission, from which his name is omitted. But until notice of the revocation of the authority, or publication of a new commission, the acts of the ex-justice are valid in law, and the warrant of a justice remains in force until it be executed, although he die before its execution. The commission is also determined by the death of the king by whom it was issued; but now, by 6 Anne, c. 7, s. 8, all offices, civil and military, are to continue for six months after the demise of the crown, unless sooner determined.

The 9 Geo. IV., c. 17, repeals the statutes which imposed the taking the sacrament of the Lord's Supper as a qualification for office, and requires the following declaration:—'I, AB, do solemnly and sincerely, in the presence of God, profess, testify, and declare, on the true faith of a Christian, that I will never exercise any power, authority, or influence which I may possess by virtue of the office of justice of the peace, to injure or weaken the Protestant church as it is by law established in England, or to disturb the said church, or the bishops and clergy of the said church, in the possession of any rights or privileges to which such church or the said bishops or clergy are or may be entitled.' The omission to subscribe this declaration does not subject a person acting as a justice of the peace to any penalty; the statute (s. 5) merely renders the appointment void; and whilst the justice continues in the exercise of his office his acts are not either void or voidable so as to affect the rights of those who are not privy to such omission.

Justices of the peace, when they are out of the county, &c. for which they are appointed, have no coercive power; but examinations, recognizances, and informations voluntarily taken before them in any place are good. But by 28 Geo. III., c. 49, justices who act for two or more adjoining counties may act in one of those counties for another of them, and those who act for a county at large may act for such county within any city, town, &c., being a county of itself, and situated within, surrounded by, or adjoining to any such county at large; and by 1 and 2 Geo. IV., c. 63, a similar power is given to county justices to act within any city, town, &c., having exclusive jurisdiction, though not a county of itself.

Justices of the peace have in general no authority over matters arising out of the district for which they are appointed, but they may secure the persons of those who are charged before them with felony or breach of the peace; and by the Municipal Corporation Act, s. 111, in every borough to which the king does not grant a separate court of quarter-sessions the justices of the county within which such borough is situated are to exercise in it the same jurisdiction as in any other part of the county.

By 24 Geo. III., c. 55, if any person against whom a warrant is issued escape, go into, reside, or be in any other county, &c., out of the jurisdiction of the justice granting the warrant, any justice of the county, &c., where such person escapes, &c., upon proof on oath of the handwriting of the justice granting the warrant, is to indorse his name thereon, which will be a sufficient authority to execute the warrant in such other jurisdiction, and carry the offender before the justice who indorsed the warrant, or some other justice of the county, &c., where it was indorsed. Summonses and warrants issued by borough justices, appointed under the provisions of the Municipal Corporation Act, in a matter within their jurisdiction, may be executed at any place within the county in which the borough is situated, or at any place within seven miles of such borough, without being backed.

The judicial authority of a justice out of sessions is both civil and criminal—civil, where he is authorized by statute to adjudicate between master and servant, or to enforce the payment of rates, tithes, &c., or the observance of the regulations of friendly societies [FRIENDLY SOCIETIES], &c.; criminal, where he requires surety of the peace or a recognizance for the peace or for good behaviour, or where he acts in the suppression of riots, or where he acts with summary power to decide upon the guilt or innocence of the party accused, according to the view which he may take of the evidence, and to punish the offender. But all proceedings before justices, whether civil or criminal, if removed into the King's Bench, are there treated as belonging to the crown side of the court.

Where a statute empowers justices to hear and determine an offence in a summary way, it is necessarily implied that the party be first cited to appear, so that he may have an opportunity of being heard, and of answering for himself; and to proceed against an offender without causing him to be summoned is a misdemeanour. A statute authorizing justices to require any person to take the oath of allegiance, or to do some other specific act, impliedly gives them power to issue their precept requiring the attendance of the party.

Upon the hearing of informations and in other preliminary proceedings before justices out of sessions neither the prisoner on the one hand, nor the prosecutor on the other, can claim as of right, and against the will of the justices, to have a legal adviser present, except, it would seem, in cases in which the deposition may by some statutory provisions be made evidence against the accused upon his trial for the offence in the event of the death of the witness. In practice however both counsel and attorneys are frequently admitted as a matter of courtesy to advise and protect the interest of prisoners. Every person has a right to be present before

a justice, acting in his judicial capacity. But although in such a case counsel or attorneys, or any third persons, are at liberty to attend, they cannot insist upon being heard on behalf of their respective clients; the justices may refuse to hear them, or to allow them to interfere with the proceedings. But now, by 6 and 7 Will. IV., c. 114, in all cases of summary conviction, persons accused are to be admitted to make their full answer and defence, and to have all witnesses examined and cross-examined by counsel or attorney. In all cases where justices are directed to take examinations or evidence, it will be implied that the examination or evidence is to be taken under the sanction of an oath or solemn affirmation.

Statutes frequently empower justices to award damages to an injured party, as in cases of assault [ASSAULT], or malicious injuries to property. [MALICIOUS INJURIES.]

Where a complaint is made before a justice, and a summons or warrant issues, the justice upon hearing and determining the matter may award costs to either party, and enforce the payment of such costs.

Justices ought not to exercise their functions in cases in which they are themselves the persons injured. They should cause the offenders to be taken before other justices, or, if present, should desire their aid. In all cases which a justice may hear and determine out of sessions upon his own view, or upon the confession of the party, or upon oath of witnesses, he ought to make a record on parchment under his hand of all the proceedings and proofs, which record should in the case of summary convictions be returned to the next sessions and there filed.

By 27 Geo. II., c. 20, in all cases where a justice is required to issue a warrant for the levying of any penalty inflicted, or any sum of money directed to be paid, by any statute, the justice granting the warrant is empowered therein to order and direct the goods distrained to be sold within a certain time, to be limited in such case (so as such time be not less than four days, or more than eight days), unless such penalty, or sum of money, with reasonable charges of taking, keeping, and selling the distress, be sooner paid.

When justices refuse to hear a complaint over which they have jurisdiction, or to perform any other duty which the law imposes on them, the party aggrieved by such refusal may apply to the court of king's bench for a writ of mandamus, a process by which the king requires the party to whom it is addressed to do the thing required or to show cause why it is not done. If no sufficient excuse be returned, a peremptory mandamus issues, by which the party is commanded absolutely to do the thing required. [MANDAMUS.] But as justices have no indemnity in respect of their acts because done in obedience to a mandamus, this process is not granted where there is anything like a reasonable doubt of the justice's authority to do the required act.

Justices of the peace are strongly protected by the law in the execution of their office. Opprobrious words which would not subject the speaker to any proceeding, civil or criminal, if uttered under other circumstances, yet if spoken of a justice whilst actually engaged in his official duties may be made the subject of an action or of an indictment, or if spoken in the presence of the justice may be punished by commitment to prison as for a contempt of court; this commitment however must be by a written warrant.

Where a justice of the peace acting in or out of sessions acts judicially in a matter over which he has jurisdiction, and does not exceed his jurisdiction, he is not liable to an action however erroneous his decision may be; nor will even express malice or corruption entitle a party aggrieved by such decision to any remedy by action: the delinquent magistrate is answerable only to the crown as for an offence committed against the public. Where the justice has no jurisdiction or exceeds his jurisdiction, or having jurisdiction deviates from the prescribed legal form to an extent which renders the proceedings void, or where a conviction under which the justice has granted a warrant is set aside by a superior court, an action will lie against the justice to recover damages in respect of any distress, imprisonment, or other injury which may have resulted from his acts, though done without malice or other improper motive. But even in these cases, if the justice has acted *bonâ fide* in his magisterial capacity, if he has intended to act within his jurisdiction, though by mistake he may have exceeded it and not acted within the strict line of his duty, and also in cases where a justice has acted or intended to act in the execution of his ministerial duties, he is entitled to the protection of several important statutory regulations, though where there is no colour whatever for a belief or supposition on the part of the justice that he is acting within his jurisdiction, where the act is wholly alien to the magisterial functions and done *diverso intuitu*, these regulations do not apply.

Thus, no action can be brought against a justice of the peace for anything done by him in the execution of his office without one calendar month's previous notice in writing, specifying the cause of the intended action, within which period of one month the justice may tender amends to the party complaining, which will be a bar to the action, if refused, and found to be sufficient by the jury. Nor can any such action be maintained unless it be commenced within six calendar months after the committing of the act complained of; nor unless it be brought or laid in the county in which the act was committed. The defendant in such action may under the general issue, *i.e.* a plea simply denying the alleged trespass, &c., give in evidence any matter of justification or excuse without being bound, as other defendants are, to select one particular line of defence, and set that defence with precision upon the record in the shape of a special plea. When the plaintiff in such action obtains a verdict and the judge certifies that the injury for which the action is brought was wilful and malicious, the plaintiff will be entitled to double costs of suit.

Where the action is brought on account of any conviction which may have been quashed, and cannot therefore be produced as a justification of the consequent distress or imprisonment, the plantiff is disabled, by 43 Geo. III., c. 141, from recovering more than 2*d.* damages, or any costs of suit unless it be expressly alleged in the declaration that the acts complained of were done maliciously and without any reasonable or probable cause.

When a justice acts with partial, corrupt, or malicious motives he is guilty of a misdemeanor, for which he may be indicted, and in a clear case of misconduct the court of King's Bench, which exercises a general superintendence over the conduct of those to whom the administration of the criminal law of the country is entrusted, will, if the application be made without delay, give leave to file a criminal information. But the court will consider, not whether the act complained of be strictly right or not, but whether it proceeded from unjust, oppressive, or corrupt motives, among which motives fear and favour are both included. If the affidavits filed in support of the application disclose nothing which may not be attributable to mere error or mistake, the court will not even call upon the justice to show cause why a criminal information should not be filed. The court will not entertain a motion for a criminal information against a justice of the peace, unless notice of the intended application have been given in sufficient time to enable him, if he thinks proper, to meet the charge in the first instance by opposing the granting of the rule to show cause.

The proceedings after an information has been filed or an indictment found against justices of the peace for criminal misconduct are the same as in other cases of misdemeanor. If the defendant suffer judgment by default, or is found guilty by the verdict of a jury, the punishment is by fine or imprisonment or both; after which an application may be made to the lord chancellor to exclude him from the commission; and when affidavits are filed in the King's Bench impeaching the conduct of justices of the peace, such affidavits are frequently directed by the court to be laid before the chancellor, to enable him to judge whether such persons ought to remain in the commission.

The institution of justices of the peace has been adopted in most of the British colonies, and has with some modifications been retained in the United States of America.

JUSTI'CIA, a genus of Acanthaceous Exogens, whose numerous species inhabit all the tropical parts of the world, preferring however damp woods to dry and open plains. It is especially in the forests of Brazil and India that they occur. Many of them are never woody, some are bushes or small trees, and a small number are valued by gardeners as objects of ornament. As limited by Linnæus, the genus comprehended a very discordant collection of species; modern writers have accordingly broken it up into many new genera. As now limited, Justicia itself scarcely contains a plant of any importance.

As among the species now removed from Justicia to other genera there are some which are useful as medicinal agents,

especially in India, it may be as well to mention them here, instead of referring to genera which are not yet generally known. Thus Justicia Adhatoda, celebrated in Sanscrit works by various names, as Vidiumatri, Vasika, &c., has been called *Adhatoda Vasika*, and is chiefly esteemed as a demulcent in coughs. *J. Nasuta* is now *Rhinacanthus communis*, and is much employed in Indian medicine, especially for the cure of ringworm and other cutaneous affections, mixed, according to Dr. Roxburgh, with lime-juice and pepper. It is also one of their remedies for snake-bites, but is no doubt inefficacious for such purpose. *Andrographis* (formerly *Justicia*) *paniculata* is the best known and probably the most valuable of all, as one of its names, *Maha tita*, implies *chief*, or *king of bitters*; it is also very commonly called *kalup-nath*, and well known to Europeans in the peninsula of India by the name of *Creyat*, or *Kreat*, and has been prescribed with benefit as a bitter in this country. It forms one of the ingredients of the *Drogue amère*, which is well known in India, and at one time obtained considerable repute as a cure for cholera; but it can be useful only as a stimulant and tonic.

JUSTICIAR OF SCOTLAND. The earliest individual in this high office which extant records name seems to be Geoffrey de Maleville of Maleville in the county of Edinburgh, *temp.* K. Malc. IV.

The term 'Scotland' was then less extensive in its application than at present: it designated, properly speaking, not the whole territory of the realm, but that part only which lay north of the Forth, or *Scots sea*, as it was called; and accordingly, contemporary with Maleville there was another justiciar, David Olifard, justiciar of Lothian, that is to say, the territory south of the Forth, excepting the district of Galloway, which had long its own peculiar laws and customs. About the middle of the thirteenth century however Galloway too had its justiciar, so at this time there were *three* justiciars in the realm of Scotland—a justiciar of Galloway, a justiciar of Lothian, and a justiciar of Scotland strictly so called. They were all probably of co-ordinate authority: each, next to the sovereign, supreme in his district; but the district of the last was the most extensive, and, containing within it the metropolis of the kingdom, it was also no doubt the most important and the most coveted. The justiciars of Scotland were accordingly the most conspicuous men of the time:—the Comyns, earls of Buchan; the MacDuffs, earls of Fife; Melville; and Sir Alan Durward. This last had an eye to the crown itself; for having married the illegitimate daughter of King Alexander II., he gained over the chancellor to move in council her legitimation, and that, on failure of issue of the king's body, she and her heirs might inherit her father's throne. But the king conceived so great a displeasure at this, that he immediately turned the chancellor out of office, and soon afterwards the justiciar also. The proud Durward removed to England, joined King Henry III. in France, and served in his army, till in a few years he was, by the influence of the English king, restored to his office of justiciar, whence he was displaced only by the more powerful Comyn. The incident in Durward's life to which we have just alluded was not singular: the justiciar was *caput legis et militiæ*, at the head both of the law and also of the military force of the kingdom, and repeated instances occur in early times of their military prowess as well as judicial firmness.

The death of King Alexander III. left the crown open to a competition which allowed Edward I. of England to invade the kingdom. In 1292 the English Court of King's Bench sat for some time in Roxburgh; and in 1296 Sir William Ormesby, a justice of the Common Pleas and justice in eyre in England was constituted, by Edward, lord justiciar of Scotland. This appointment was of short duration; but in 1305 Edward, having again put down the Scots, distributed the kingdom into four districts, and constituted for each district two justices (an Englishman and a Scotchman), in the nature of the English justices of assize—with a view to put the whole island under one and the same judicial system. Edward's early death however rendered the scheme abortive; and Galloway had soon its own laws, and Lothian and Scotland their justiciars as before, with this difference, that the metropolis of the kingdom was now shifting southwards to Edinburgh, and the term Scotland, in its strict acceptation, had given place to the appellation 'north of the Forth.' Sir Hugh de Eglinton, justiciar of Lothian in the middle of the fourteenth century, and distinguished for his poetical genius, was now therefore 'Hugh of the Awl Ryal,' or of the royal palace; and towards the end of the next century Andrew lord Gray was advanced from the situation of justiciar north of Forth to that of justiciar south of Forth. He continued in this place with approbation for eleven years, and died but a few months before the calamitous affair of Flodden.

On this event, which happened in the beginning of the sixteenth century, the office of lord justiciar, or, as he was now styled, justice-general (in contradistinction to the special justiciars, now frequently appointed as well for particular trials as for particular places and districts), came into the noble family of Argyle, where it was hereditary for a century, and comprehended at once the entire kingdom. The High Court of Justiciary then also began to be settled at Edinburgh, and the regular series of its records, or books of adjournal, to commence. It was at this time also that the Court of Session was erected by ecclesiastical influence. Various attempts had been made by the clergy in former reigns to establish such a court. In 1425 the first 'Court of the Session' was instituted under the influence of Wardlaw, bishop of St. Andrew's and founder of the university there; but immediately on his death, which happened soon after, it drooped and expired. In 1458 Bishop Shoreswood, the king's secretary, tried to revive it; and about thirty years after, Elphinstone, bishop of Aberdeen, did so likewise. In 1494 however the latter founded, or rather re-founded, the university of Aberdeen, and had interest enough to get an act passed in parliament to enforce in all the courts of the kingdom the study and practice of the Roman laws; and in 1503 the 'Court of Daily Council' was established. This court had a more extensive jurisdiction than the former: it was universal, being instituted to decide all manner of summonses in civil matters, complaints, and causes daily as they happened to occur; and it was calculated to be permanent. But the present was not an opportunity to be lost; and accordingly, in the minority of King James V. and while the nation was weakened and distracted by the loss at Flodden, the Court of Session was established under the lord chancellor, and with a majority of ecclesiastics both on its bench and at its bar. The consequence was, that from that day forward the Court of Justiciary declined; its civil jurisdiction ceased, being engrossed by the Court of Session: and the latter became in its place the supreme court of the kingdom. The Reformation effected a change in the composition of the Court of Session, but not much in its position or powers; and in 1672 an act was passed in parliament constituting a certain number of the judges, or lords of session, judges of justiciary under the justice-general and justice-clerk, who was now made vice-president of the Court of Justiciary.

Nothing else of consequence touching the constitution of the court occurred till lately, when, by 1 Will. IV., c. 69, sec. 18, the office of lord justice-general, which had become in a manner a perfect sinecure, was appointed to devolve on and remain with the office of lord-president of the Court of Session, who should perform the duties thereof as presiding judge in the Court of Justiciary. The effect of which enactment is to place the lord-justice-general again at the head of the administration of the law; and thus, by a singular revolution, restore him, after the elapse of 300 years, to his former situation of lord chief justice of Scotland.

JUSTICIARY, CHIEF, of England (*Capitalis Justitiarius Angliæ*). None either of the English lawyers or legal antiquaries who have handled this subject appear to have given at all a satisfactory explanation of it. As the following passage in the 'Pictorial History of England' affords the best explanation of the difficulty that we have met with, we consider it but fair to give it as it stands in that work. It will be observed that in order to comprehend the functions of the chief justiciary it is necessary first to understand those of 'The *Grand Seneschall*, or *Dapifer*—*Senescallus*, or *Dapifer* Angliæ*; in modern phraseology, the lord high steward—*comes palatii*, *major domus regiæ*, or *maire du palais*. The word *seneschalch*, about the etymology of which opinions vary somewhat, meant originally a

* 'That these terms are synonymous, is shown by Ducange, Spelman, &c. Dapifer seems to have been introduced when a Latin word came to be wanted for seneschall, and was adopted for want of a better, there being no Latin term exactly corresponding. Dapifer has been ignorantly translated "sewer" by Dugdale and others; whereas sewer, so far from meaning seneschall, means only *ecuyer tranchant*, an officer a great many degrees below the seneschall. See Ducange, *ad voc. Dapifer, Senescallus*; Spelman, *ad voc. Dapifer, Capitalis Justitiarius, Senescallus*, and Dugdale's 'Baronage.'

sort of steward in the household of the Frank kings. After their conquest of Gaul, it came to signify a high political dignity.* Dapifer, as shown in the note below, means the same thing, being the Latin synonyme for it. This officer was the highest in the state after the king, executing all the chief offices of the kingdom as the king's representative. He was not only at the head of the king's palace, but of all the departments of the state, civil and military, chief administrator of justice, and leader of the armies in war. This is proved not only to have been the case in France, by Ducange and other high authorities, as well as by the public records of that kingdom,* but to have been so also in England, by a document published by Madox himself, from the black and red books of the Exchequer—to wit, the celebrated *Dialogus de Scaccario*, written in the time of Henry II.;† and likewise by certain MSS. preserved in Sir Robert Cotton's collection in the British Museum, particularly an old MS. entitled "Quis sit Seneschallus Angliæ, et quid ejus officium."‡ Consequently, Madox is wrong when he says ("Hist. Excheq.," p. 28) that in the reign of William I., William Fitz-Osbern was the king's constable, *because* he is called *magister militum*. Whereas in the very same passage (of "Ordericus Vitalis") he is called *Normanniæ Dapifer*, in virtue of which office he would be *magister militum*. It was not till afterwards that the constable became magister militum, being originally an officer subordinate to the dapifer.' (*Pictorial History of England*, vol. i. p. 567.)

By the nature of the feudal system everything had a tendency to be given in fief. 'Among other things, the office of seneschal was given in fief too, and became hereditary among the Franks, Normans, and, at the conquest of England, among the Anglo-Normans. In France, under the Merovingian dynasty, the office was in the family of Charles Martel, from whom sprung the Carlovingian dynasty; afterwards the Plantagenet counts of Anjou were hereditary seneschals of France; and in England this high office was granted by William the Conqueror to the Grantmesnils, and thence came by marriage to the earls of Leicester. After the attainder of the family of Montfort, earls of Leicester, the office was given to Edmund, the second son of King Henry III., and it then remained in the royal family till its abolition—Thomas Plantagenet, second son of King Henry IV., being the last permanent high steward,§ the office being conferred afterwards only *pro unicâ vice*.

'In France, when the office became hereditary in the counts of Anjou, it soon became necessary, for various reasons, to have another seneschal, or dapifer, besides the hereditary one; and this officer, whether he be considered as the representative or deputy of the hereditary seneschal, still took precedence, as appears from the charters of the French kings, of all the other great officers of state. In England also something of the same kind took place, but with this difference—that the various functions of the original grand seneschal, or *senescallus Angliæ*, were divided into two parts, and committed to two distinct officers as his representatives; the judicial functions being committed to an officer styled the High, or rather Chief Justiciary; the administrative and those relating to the affairs of the king's palace or household, to an officer styled, *not* the Senescallus *Angliæ*, but the Senescallus, or Dapifer *Regis*.‖ This explanation will be found to completely remove the confusion that has so long prevailed among the English historians, antiquaries, and lawyers on this subject. Our view of the subject, if it needed it, would be corroborated by the high privileges of the officer created in later times, to preside in the House of Lords at state trials, which officer, be it observed, is not "high justiciary," but "lord high steward," that is "*Senescallus Angliæ*." This explanation also removes the difficulty of accounting for the extraordinary powers of the lord high steward's court, which some English lawyers have attempted to get over, by saying that the lord high steward succeeded to some of the powers of the high justiciary, whereas he merely exercises powers which he had delegated to the high justiciary.'*—(*Ibid.*)

The chief justiciary was usually, even in those times, when, from the circumstance of the king and the great officers of his household acting as judges, we may conclude that a special education was not considered absolutely necessary to fit a man for the judicial office, a person who had given particular attention to the study of jurisprudence. As the representative of the judicial portion of the grand seneschal's power, his authority extended over every court in the kingdom. For as to what Blackstone says† of the court of the marshalsea, *i.e.* the court of the lord steward of the king's household, having never been subject to the jurisdiction of the chief justiciary and no writ of error lying from it to the king's bench, it merely amounts to this, that the court of the lord steward was in fact originally the court of the lord high steward, and in that court either of his representatives, the chief justiciary or the lord steward, might preside.

The chief justiciary not only presided in the king's court and in the exchequer, but he was originally (or rather when the lord high steward fell into abeyance, partly from dread of his power and partly from the impossibility of securing an hereditary succession of the qualities necessary to fulfil his great and numerous duties), by virtue of his office, regent of the kingdom during the king's absence, and at those times writs ran in his name, and were tested by him.‡ And in this light the chief justiciary is regarded as having been the greatest subject in England. One of the most distinguished men who held this high office was Ranulph de Glanville, who is usually regarded as the author of the *Tractatus de Legibus et Consuetudinibus Angliæ*, the oldest book extant on English law.§

The last who held the office and bore the title of *Capitalis Justitiarius Angliæ* was Philip Basset: and the first who held the office of *Capitalis Justitiarius ad placita coram Rege tenenda*, *i.e.* chief justice of the king's bench, was Robert de Bruis, appointed in the fifty-second year of Henry III.‖ Sir Edward Coke was fond of indulging his vanity by bestowing the same title, 'Chief *Justice* of England,' upon himself and on the Grand Justiciary, the mighty *Capitalis Justitiarius Angliæ*; which was noticed by Lord Chancellor Ellesmere in his address to Sir Henry Montague, Coke's successor, upon his being sworn in chief justice, in these words:—'instead of containing himself within the words of the writ to be the chief justice, as the king called him, "ad placita coram nobis tenenda."'

JUSTIFICATION is used in theology to signify the acceptance of a sinner by God, and is frequently employed by the sacred writers as equivalent to the forgiveness of sin. Thus, St. Paul says, 'Be it known unto you therefore, men and brethren, that through this man is preached unto you the forgiveness of sins, and by him all that believe are justified from all things from which ye could not be justified by the law of Moses.' (*Acts*, xiii. 38, 39.) The Protestants and Roman Catholics differ respecting the signification that should be attached to the word justification. The former maintain that the Hebrew word הִצְדִּיק, and the Greek words δικαιοῦν and δικαίωσις, are almost invariably employed in the Bible in a judicial sense; that is, to declare a person righteous notwithstanding the sins he has committed, and to deliver him from the punishment which his sins had deserved. The latter interpret the words in a physical sense; and maintain that to be justified is not to be reckoned righteous by God, but actually to be made righteous by the infusion of a sanctifying principle. The Protestants,

* 'Ducange, Gloss., ad voc. Dapifer et Senescallus. See also the "Grand Coustumier de Normandie," c. x. "Solebat autem antiquitus quidam justiciarius prodictis *superior* per Normaniam discurrere qui seneschallus principis vocabatur."—Conf. "La Coutume Reformée de Normandie commentée par Basnage," t. i, p. 2, col. 2 (Senéschal). See also the charters of the various Frank kings, in the witnessing of which the name of the seneschal or dapifer (sometimes the one word is used, sometimes the other) always stands before those of all the other great officers. It is right to add, that in the English charters, the name of the dapifer, or seneschal, does not *invariably* stand so high as in the French.'

† 'Madox, "Hist. Exchequer" (edition 1711). See also "Co. Litt.," fol. 61 a, for some account of the judicial part of the office of seneschal, or steward, and some attempt at the etymology of the word, not much more successful than attempts of that kind usually are.'

‡ 'Cotton MSS. Vespasian, b. vii., fol 99, b. It will also be found in Harl. MSS. 305, fol. 48, transcribed in a modern hand by D Ewes, who supposed it to be of the age of Edward II. See also Cotton MSS., Titus C. *passim*, at the beginning of which volume there is a well-written tract, which contains the most satisfactory account we have met with of the subject. There is also a tract entitled "Summus Angliæ Seneschallus," in Somers's Tracts, vol. viii. All these agree in one thing, viz.—the vastness and paramount nature of the authority *originally* wielded by the high steward, though none of them explain the anomaly of the co-existence of such an officer as the high justiciary. This we hope we shall now be enabled to do.'

§ 'For a list of high stewards see Harl. MSS 2194.'

‖ 'Among many other proofs of this, see Madox's "Form. Anglic.," cclxxxix.'

* 'See a Disquisition on the Office of Lord High Steward, by Mr. Amos, in Phillips's "State Trials," Appendix, vol. ii. Mr. Amos falls into the usual error of supposing that the judicial authority of the lord high steward grew out of that which appertained to the chief justiciar at the period when the latter office was abolished.'

on the contrary, believe, that though sanctification is a consequence of justification, yet it is a distinct and separate operation.

The reason or cause of our justification is generally divided by theologians into the originating, the meritorious, and the instrumental cause, or the *causa efficiens*, the *causa meritoria*, and the *causa apprehendens*.

1. The *Originating cause* is the love of God towards his fallen creatures (*Rom.* iii. 24; *Eph.* ii. 8). 2. The *Meritorious cause* is, according to the 11th article of the Church of England, and the opinion of most Protestants, 'the merit of our Lord and Saviour Jesus Christ, and not our own works or deservings' (*Rom.* iii. 24; v. 18; *Eph.* i. 7; *Col.* i. 14); but the Roman Catholic church maintains that good works, penances, and the intercession of saints also contribute to our justification. 3. The *Instrumental cause* is faith in the vicarious sacrifice of Christ; since the merit of Christ's sacrifice does not produce our pardon, unless we believe in its efficacy.

The consequences of justification are said to be: 1. peace with God (*Rom.* v. 1); 2. tranquillity of conscience; 3. adoption of the persons justified into the family of God (*Rom.* viii. 14-17); 4. spiritual joy, arising from the belief of our being adopted by God (*Rom.* xiv. 17); 5. the hope of eternal life.

JUSTINIAN'S LEGISLATION. Justinian, soon after ascending the throne, gave orders (Feb. A.D. 528) to a commission consisting of Joannes and nine other persons, among whom were Tribonian or Tribunian, and Theophilus, to make a general compilation of the best and most useful laws, or 'constitutions,' which had been promulgated by the emperors his predecessors, beginning from Hadrian's perpetual edict down to his own time. [CONSTITUTIONS, ROMAN.] Partial compilations had been made in the time of Constantine by private individuals, Gregory and Hermogenes, of which only fragments remain, and a more complete one was effected under Theodosius II. [THEODOSIAN CODE.] All these were now merged in the new code of Justinian. A remarkable difference of style and manner is observable between the older constitutions issued before Constantine and those promulgated afterwards. The former being issued at Rome and framed upon the decisions, or 'responsa,' of learned jurists, are clear, sententious, and elegant; the latter, which were promulgated chiefly at Constantinople in the decay of the Roman language, are verbose and rhetorical. Joannes and his nine associates completed their task in fourteen months, and the new code, having received the imperial sanction, was published in April, A.D. 529. A few years after, Justinian, by the advice of Tribonian, ordered a revision of his code to be made by Tribonian and four others. These commissioners suppressed several laws, as either useless or inconsistent with present usage, and added many constitutions which the emperor had been promulgating in the mean time, as well as fifty decisions on intricate points of jurisprudence. The code thus revised was published in December of the year 534, under the title of 'Codex Justinianeus repetitæ prælectionis,' and thenceforth had the force of law.

The Code is divided into twelve books; every book is subdivided into titles, and each title into laws. Book i. treats of the Catholic faith, defines its creed agreeably to the first four general councils, forbidding public disputations on dogmas; it then treats of the rights, privileges, and discipline of bishops and other ecclesiastical persons; next of heretics, Samaritans, Jews, apostates, &c., against whom it contains several penal enactments; after which the book proceeds to speak of the laws, and their different kinds, and lastly of the magistrates. Book ii. treats of the forms to be observed in commencing a suit; then of restitution, compromises, sureties, and lastly of the oath of calumny.* Book iii. treats of judicia and judices, and judicial proceedings generally; of holidays, of the various jurisdictions, of illegal (inofficiosa) testaments and donations, of dowries and inheritances, of the Lex Aquilia, of mixed actions, of actions for crimes committed by slaves, of gaming, of burying-places and funeral expenses. Book iv. begins with the explanation of personal actions which are founded on loan and other causes; of obligations and actions, with their effect in relation to heirs and other persons bound by them; of testimony and written evidence; of things borrowed for use; of contract by pledge, and the personal action thereon; of compensation, interest, deposit, mandate, partnership, buying and selling, permutation, hiring, and emphyteutic contracts. Book v. treats of betrothment, gifts in contemplation of marriage, of marriages, women's portions, and the action that lies for the recovery of the dowry, of gifts between husband and wife, of estates given in dowry, of alimony, of concubines, natural children, and the process of legitimation. It next treats of tutorships (tutela), of the administration by tutors, and of the alienation of minors' estates. Book vi. treats of slaves, and freedmen, and the rights of their patrons; then it explains at large the Prætorian possession called 'Bonorum possessio:' after which it expounds the whole matter of testaments, as institutions and substitutions of heirs, preteritions and disinheritings, refusals of inheritance, the opening of wills, codicils, legacies, and fiduciary bequests, and lastly succession to the property of intestates. Book vii. treats of manumissions; afterwards of matters relating to prescription, of judgments (sententiæ) and appeals, of the cession of estate or goods, of the seizure of goods, of the privileges of the exchequer, those of dowries, and the revocation of alienations made to defraud creditors. Book viii. begins with interdicts: it then treats of pledges and pawns, of stipulations, novations, delegations, &c. It treats next of the paternal power, of the emancipation of children, and their ingratitude; it then explains what is meant by custom, or unwritten law; it next speaks of gifts (donationes mortis causâ, &c.) and their various kinds; and lastly, of taking away the penalty of celibacy. Book ix. treats of crimes, criminal judgments and punishments. Book x. treats of the rights and prerogative of the exchequer, of vacant goods, of treasurers, taxes levied upon the people, and tolls; of the decuriones and their office, of the freedom of citizens, of domicilia, of public offices and exemption from them, and of the various kinds of public offices and functions appertaining to them. Book xi. treats of the rights common to the city of Rome and municipal towns, the right of having corporate bodies and communities, and the right of having public registers. Book xii. continues the same subject, explaining the right of cities as to having offices civil and military, and also as to having functionaries for the execution of judgments and the orders of magistrates.

The learned Gothofredus, in his Prolegomena attached to his edition of the Theodosian code, observes that Tribonian and his associates have been guilty of several faults in the compilation of the Code; that the order observed in the succession of the titles is confused, that some of the laws have been mutilated and have been rendered obscure, that sometimes a law has been divided into two, and at other times two have been reduced to one; that laws have been attributed to emperors who were not the authors of them, or had given quite contrary decisions; all which would be still more injurious to the study of the Roman law, if we had not the Theodosian code, which is of great use towards rightly understanding many laws in the code of Justinian.

In the year following the publication of the first edition of his Code, Justinian undertook a much greater and more important work; to extract the spirit of jurisprudence from the decisions and conjectures, the questions and disputations, of the Roman civilians. In the course of centuries, under the republic and the empire, many thousand volumes had accumulated, filled with the learned lucubrations of the jurisconsults, but which no fortune could purchase, and no capacity could digest. The jurisconsults ever since the time of Augustus had been divided into opposite schools, and thus conflicting opinions were often produced, which only served to puzzle those who had to decide what was law. To put order into this chaos, was the object of Justinian. In December, 530, he commissioned seventeen lawyers, with Tribonian at their head, with full authority to exercise their discretion as to the works of their predecessors, by making a choice of those whom they considered as the best authorities. They chose about forty out of Tribonian's library, most of them jurisconsults who had lived during that period of the empire which has been sometimes called the age of the Antonines, from Hadrian to the death of Alexander Severus. From the works of these writers, said to have amounted to two thousand treatises, the commission appointed by Justinian was to extract and compress all that was suited to form a methodical, complete, and never failing book of reference for the student of law and the magistrate. Justinian gave Tribonian and his associates ten years' time to perform their task; but they completed it in three years. The work

* Many of the terms here used are terms of Roman law, and as such do not admit of translation by equivalent English terms.

was styled 'Digesta,' and also 'Pandectæ' ('embracing all'), and was published in December, 533. It was declared by the emperor that it should have the force of law all over the empire, and should supersede all the text books of the old jurists, which in future were to be of no authority.

The following is a list of the Roman jurists from whose works the 'Pandect' or 'Digest' was composed, with their several epochs, so far as they can be ascertained, and the relative proportions which they have contributed to the 'Pandect.' Where (*a*) is added, the contribution is less than 1. The sum total of all the figures denotes the whole amount, of which the several figures opposite each jurist's name denote the proportion which his part bears to the whole. In addition to the extracts contained in the 'Pandect' from each author, many of them are very often merely cited.

Aburnus (Valens).
Ælius (Gallus, Marcianus).
Æmilius (Macer, Papinianus).
Africanus, lived in Hadrian's time and was a disciple of Salvius Julianus 24
Alfenus, a native of Cremona, and a pupil of Servius Sulpicius, who died B.C. 43. 9
Anthianus, time unknown . . . . . (*a*)
Anthus (Anthianus).
Antistius (Labeo).
Aquila, supposed by some to have lived under Sept. Severus . . . . (*a*)
Arcadius, under Constantine the Great . . . $2\frac{1}{2}$
Arrius (Menander).
Aurelius (Arcadius).
Cæcilius (Africanus).
Caius (Gaius).
Callistratus, under Caracalla . . . . $17\frac{1}{2}$
Celsus, lived under Trajan and Hadrian . 23
Cervidius (Scævola).
Charisius (Arcadius).
Claudius (Hermogenianus, Saturninus, Tryphoninus).
Clemens (Terentius).
Domitius (Ulpianus).
Florens (Tertullianus).
Florentinus, time uncertain, supposed to have lived under Alex. Severus 4
Furius (Anthianus).
Gaius, lived under Antoninus and Aurelius . 72
Gallus, Aquilius, a friend of Cicero, with whom he was prætor, B.C. 66 . . . . . . (*a*)
Herennius (Modestinus).
Hermogenianus, under Constantine . . . $9\frac{1}{2}$
Javolenus, lived under Trajan . . . . $23\frac{1}{2}$
Julianus, lived under Hadrian, was a pupil of Javolenus, and author of the perpetual edict . 90
Julius (Aquila, Paulus).
Junius (Marcianus).
Justus (Papirius).
Juventius (Celsus).
Labeo, lived under Augustus, was the head of the school called Proculeians from his disciple Proculus 12
Licinius (Rufinus).
Lucius (Mæcianus, Papinianus).
Macer, under Alexander Severus, ... 10
Mæcianus, lived under Antoninus Pius . . 8
Marcellus, under Antoninus and Aurelius . $32\frac{1}{2}$
Marcianus, probably under Caracalla . . 38
Marcus (Labeo).
Massurius (Sabinus).
Mauricianus, lived under Antoninus . . $1\frac{1}{2}$
Maximus, time unknown . . . . . (*a*)
Menander, under Severus and Caracalla . 3
Modestinus, flourished under Alex. Severus and the Maximini . . . . $41\frac{1}{2}$
Mucius, Quintus, son of P. Mucius Scævola, consul in the year 659 of Rome, or B.C. 95 . . 1
Neratius, lived under Trajan 10
Papinianus, under Sept. Severus, whose friend he was; was put to death by Caracalla . . . 104
Papirius, under Marcus Aurelius . . . $2\frac{1}{2}$
Paternus (Tarruntenus).
Paulus, flourished under Alexander Severus . 297
Pomponius, lived under Antoninus Pius; another Pomponius is said to have lived under Alex. Severus 80
Priscus (Javolenus, Neratius).
Proculus, lived under Nero and Vespasian . 6
Publius (Alfenus, Anthianus, Juventius).
Quintus (Mucius, Tertullianus, Venuleius).
Rufinus, about the time of Alex. Severus . $1\frac{1}{2}$
Rutilius (Maximus).
Sabinus, Massurius, flourished under Tiberius, was the head of the Sabinian school . . $1\frac{1}{2}$
Salvius (Julianus).
Saturninus, supposed by some to be the same as Venuleius 1
Saturninus Quintus (Venuleius).
Scævola, Cervidius, under Antoninus and Aurelius . . . . $78\frac{1}{2}$
Scævola, Mucius (Mucius).
Sempronius (Proculus).
Septimius (Tertullianus).
Sextus (Pomponius).
Tarruntenus, under Marcus and Commodus . (*a*)
Terentius, lived under Hadrian and Antoninus $3\frac{1}{2}$
Tertullianus, time uncertain, by some supposed to be the same as the father of the church . . $1\frac{1}{2}$
Titus (Gaius).
Tryphoninus, under Severus and Caracalla . 22
Valens, lived under Hadrian and Antoninus Pius 3
Varus (Alfenus).
Venuleius, under Antoninus and Aurelius . 10
Ulpianus, flourished under Alex. Severus, whose counsellor he was 610
Ulpius (Marcellus).
Volusius (Mæcianus).

If the whole 'Digest' is divided into three equal parts, the contributions of Ulpian are somewhat more than one-third.

The 'Digesta' is divided into 50 books, each book being also divided into titles, and subdivided into sections. The following are some of the principal heads. Book i. lays down the general principles and the different kinds of law; it then establishes the division of persons and of things; then speaks of senators, and of magistrates and their delegates and assessors: ii. treats of the jurisdiction of magistrates; of the manner of bringing actions, of compromises after an action is commenced: iii. explains what kind of persons are allowed to sue in law, and it defines who are styled infamous, and as such not permitted to sue: it then treats of advocates, proctors, syndics, and other counsellors: iv. treats of restitution, compromises, and arbitrations, after which it speaks of innkeepers and others in whose custody we leave anything: v. treats of trials: and complaints against inofficious (inofficiosa) testaments: vi. treats of real actions and their various kinds to recover one's property: vii. treats of personal services (servitutes, as usus fructus): viii. speaks of real services both in town and country: ix. treats of personal actions which are in imitation of real actions, as actions for a fault or crime committed by a slave, the action of the lex Aquilia, and the action against those who throw any thing into the highway by which any one is wounded or injured: x. treats of mixed actions, the action of partition of an inheritance, &c: xi. speaks of interrogatories, and of such matters as are to be heard before the same judge (judex). It also treats of run-away slaves, of dice-playing, bribery, corruption, and false reports; and lastly, of burials and funeral expenses: xii. explains the action for a loan, condictions, &c.: xiii. continues the subject of the preceding, and treats of the action of pawning: xiv. and xv. treat of actions arising from contracts made by other persons and yet binding upon us; of the Senatus Consultum Macedonianum; and of the peculium: xvi. treats of the Senatus Consultum Velleianum, and of compensation, and the action of deposits: xvii. treats of the mandate, and of partnership (societas): xviii. explains the meaning and forms of the contract of sale, the annulling of this kind of contract; and treats of gain or loss upon the thing sold: xix. treats of bargains, of actions of hiring, of the action called æstimatoria, of permutation, of the action called præscriptis verbis, &c.: xx. treats of pledges and hypothecæ, of the preference of creditors, of the distraction or sale of things engaged or pawned: xxi. contains an explanation of the Ædile's edict concerning the sale of slaves and beasts, and also treats of evictions, warranties, &c.: xxii. treats of interest (usuræ), fruits, accessions to things, and of proofs and presumptions, and of ignorance of law and fact: xxiii. is upon betrothment (sponsalia), marriage, dowry, and agreements upon this subject, and lands given in dowry: xxiv. treats of gifts between husband and wife, divorces, and recovery of the marriage portion: xxv.

treats of expenses laid out upon the dowry, of actions for the recovery of things carried away by the wife or other person against whom there is no action for theft, of the obligation to acknowledge children and provide for them, on the Rescript De Inspiciendo Ventre, and lastly of concubines: xxvi. and xxvii. treat of tutorship and curatorship, and the actions resulting from them: xxxviii. treats of testaments, of the institution and disinheriting of children, of the institution of an heir, of substitutions, &c.: xxix. treats of military testaments, of the opening of wills, and of codicils: xxx., xxxi., xxxii. treat of legacies and fiduciary bequests in general: xxxiii. and xxxiv. treat of particular legacies, of the ademption of legacies, and of the Regula Catoniana: xxxv. treats of legacies on condition, and of the Lex Falcidia: xxxvi. treats of the Senatus Consultum Trebellianum, and of fiduciary bequests, of the time when they become due, of the security to be given by the heir, &c.: xxxvii. treats of universal succession by bonorum possessio: xxxviii. treats of the services due by freedmen to their patrons, of the succession of freedmen, of the succession of intestates appointed by the prætor, of heredes Sui and Legitimi, and of the Senatus Consultum Tertullianum and Orphitianum: xxxix. explains the means which the law or the prætor provides for preventing any one from receiving damage where a personal, real, or mixed action will not lie, after which it ends with the explanation of donations generally, and of such as are made in contemplation or view of death (mortis causâ): xl. relates to manumission or freeing of slaves: xli. treats of the various ways by which the property of things is acquired, and of the acquisition and loss of possession, and lastly of lawful causes which authorize possession and lead to usucaption: xlii. treats of definitive and interlocutory sentences, of confessions in judgment, of the cession of goods, of the causes of seizure and their effects, of the privileges of creditors: of curators appointed for the administration of goods, and of the revocation of acts done to defraud creditors: xliii treats of injunctions (interdicta) and possessory actions: xliv. speaks of pleas (exceptiones) and defences, and of obligations and actions: xlv. of stipulations, &c.: xlvi. of sureties, novations, delegations, payments, discharges, prætorian stipulations, &c.: xlvii. treats of private offences: xlviii treats of public offences; then follow accusations, inscriptions, prisons; and lastly it treats of torture, punishments, confiscation, relegation, deportation, and of the bodies of malefactors executed: xlix. treats of appeals; and then gives an account of the rights of the exchequer, and of matters relating to captives, military discipline, soldiers and veterans: l. treats of the rights of cities and citizens, of decuriones and their children, of public offices, of immunities, of deputies and ambassadors; of the administration of things belonging to cities, of public works, fairs, &c.; of taxes laid upon the provinces, and lastly it concludes with the interpretation and signification of legal terms, and with the rules of law.

Of the merits and imperfections of the 'Digest,' Cujas, Hotomannus, Heineccius, Gravina, Schulting, Bynkershoek, and many others have amply spoken. With all its faults it is a noble work, and much superior to the Code in its style, matter, and arrangement; it has, in great measure, embodied the wisdom of the most learned men of the best age of the Empire, men who grounded their opinions on the principles of reason and equity, and who for the most part were personally unconcerned and disinterested in the subjects on which they gave their responsa. Tribonian and his colleagues are charged with making many interpolations, with altering many passages in the writings of their predecessors, substituting their own opinions, and passing them off to the world under the name of the antient jurists. Justinian himself acknowledged that he was obliged to accommodate the old jurisprudence to the altered state of the times, and to 'make the laws his own.' Another charge, which is however unsupported by evidence or probability, is, that Justinian and his civilians purposely destroyed the old text books that had served them for the compilation of the 'Pandects.' Long however before Justinian's time, the works of the antient jurists were partly lost, and the vicissitudes of the ages that followed may easily have obliterated the rest. While the Digest was being compiled, Justinian commissioned Tribonian and two other civilians, Theophilus and Dorotheus, to make an abridgment of the first principles of the law, for the use of young students who should wish to apply themselves to that science. This new work, being completed, was published under the name of 'Institutiones,' about one month before the appearance of the Digest. The Institutions were mainly based on an older work of the same description and title. [GAIUS.] They are arranged in four books, subdivided into titles. As the law has three objects, persons, things, and actions, the first book treats of persons or status; the second and third, and first five titles of the fourth, treat of things; and the remaining titles of the fourth book treat of actions. [ROMAN LAW.]

Besides these three compilations, the Code, the Institutes, and the Digest, Justinian, after the publication of the second edition of his Code, continued to issue new laws or constitutions chiefly in Greek upon particular occasions, which were collected and published together after his death under the name of Νεαραί Διατάξεις, or Novæ or Constitutiones Novellæ, or Authenticæ. The Novellæ are divided into nine Collationes and 168 Constitutiones, or, as they are now often called, novels. The Novellæ, together with thirteen Edicts of Justinian, make up the fourth part of his legislation. There are four Latin translations of the Novellæ, two of which were made soon after Justinian's death; the third is by Haloander, printed at Nürnberg in 1531; and the fourth was printed at Basel by Hervagius in 1561. This first translation is that which is printed in the editions of the Corpus Juris opposite to the Greek text, and is very valuable, notwithstanding it has been stigmatized by some with the name 'barbarous:' it is sometimes called Authentica Interpretatio or Vulgata. The version of Haloander is also printed in some editions of the Corpus Juris. The Novellæ made many changes in the law as established by Justinian's prior compilations, and are an evidence that the emperor was seized with a passion for legislating; a circumstance which enables us to form a more correct judgment of his real merits, and lowers his character as a philosophic jurist.

A few words on Tribonianus, who was so mainly instrumental in the compilation of Justinian, may not be misplaced here. He was a native of Pamphylia, and his father was from Macedonia. His learning was most extensive: he wrote upon a great variety of subjects, was well versed both in Latin and Greek literature, and had deeply studied the Roman civilians, of which he had a valuable collection in his library. He practised first at the bar of the prætorian prefects at Constantinople, became afterwards quæstor, master of the imperial household, and consul, and possessed for above twenty years the favour and confidence of Justinian. His manners are said to have been remarkably mild and conciliating; he was a courtier, and fond of money, but in other respects he appears to have been calumniated by his enemies. He was a superior man, and most valuable to Justinian. His death took place A.D. 545. (Ludewig, *Vita Justiniani Magni atque Theodoræ, nec non Triboniani*, Halle, 1731; Zimmern, *Geschichte des Römischen Privatrechts bis Justinian*, Heidelberg, 1826; Hugo, *Lehrbuch der Geschichte des Römischen Rechts*, Berlin, 1832; *History of the Roman or Civil Law*, by Ferriere, translated by J. Beaver, London, 1724; Hommelii, *Palingenesia*; Brinkmannus, *Institutiones Juris Romani*, Schleswig, 1822; *System des Pandekten Rechts*, by Thibaut, 7th ed., Jena, 1828; *Das Corpus Juris in's Deutsche übersetzt von einem Vereine Rechtsgelehrter und herausgegeben von* Otto, Schilling und Sintenis, Leipzig, 1831; *Les Cinquante Livres du Digeste, &c., Traduits en Français par feu* M. Henri Hulot, Paris, 1805; *Pandectes de Justinien mises dans un nouvel ordre, &c., par R. J. Pothier, traduites par Bréard Neuville, revues et corrigées par* M. Moreau de Montalin, Avocat, Paris, 1810; Pothier's edition of the *Digest*, reprinted at Paris in 5 vols. 4to., 1818—20, is a useful edition; there is a very cheap edition of the *Corpus Juris* recently published in Germany, by Beck, 3 vols. small fol., Leipzig, 1829; the editions of the Corpus Juris and of the Institutes are very numerous.) [CORPUS JURIS; GAIUS.]

JUSTINIA'NUS, FLA'VIUS, born near Sardica in Mœsia, A.D. 482 or 483, of obscure parents, was nephew by his mother's side to Justinus, afterwards emperor. The elevation of his uncle to the imperial throne, A.D. 518, decided the fortune of Justinian, who, having been educated at Constantinople, had given proofs of considerable capacity and application. Justinus was ignorant and old, and the advice and exertions of his nephew were of great service to him during the nine years of his reign. He adopted Justinian as his colleague, and lastly, a few months before his death, feeling that his end was approaching, he crowned him in presence of the patriarch and senators, and made over the imperial authority to him, in April, 527. Justi

nian was then in his forty-fifth year, and he reigned above thirty-eight years, till November, 565, when he died. His long reign forms a remarkable epoch in the history of the world. Although himself unwarlike, yet by means of his able generals Belisarius and Narses he completely defeated the Vandals and the Goths, and re-united Italy and Africa to the empire. Justinian was the last emperor of Constantinople who, by his dominion over the whole of Italy, re-united in some measure the two principal portions of the antient empire of the Cæsars. On the side of the East the arms of Justinian repelled the inroads of Khosroes, and conquered Colchis; and the Negus or king of Abyssinia entered into an alliance with him. On the Danubian frontier the Gepidæ, Longobards, Bulgarians, and other hordes were either kept in check or repulsed. [BELISARIUS.] The wars of Justinian's reign are related by Procopius and Agathias.

Justinian must be viewed also as an administrator and legislator of his vast empire. In the first capacity he did some good and much harm. He was both profuse and penurious; personally inclined to justice, he often overlooked, through weakness, the injustice of subalterns; he established monopolies of certain branches of industry and commerce, and increased the taxes. But he introduced the rearing of silkworms into Europe, and the numerous edifices he raised, the towns he repaired or fortified, attest his love for the arts, and his anxiety for the security and welfare of his dominions. Procopius, 'De Ædificiis Domini Justiniani,' gives a notice of the towns, temples (St. Sophia among the rest), convents, bridges, roads, walls, and fortifications constructed or repaired under his reign. The same Procopius however wrote a secret history ('Anecdota') of the court and reign of Justinian and his wife Theodora, both of whom he paints in the darkest colours. Theodora indeed was an unprincipled woman, with some abilities, who exercised, till her death in 548, a great influence over the mind of Justinian, and many acts of oppression and cruelty were committed by her order. But yet the 'Anecdota' of Procopius cannot be implicitly trusted, as many of his charges are evidently misrepresentations or malignant exaggerations. Justinian was easy of access, patient of hearing, courteous and affable in discourse, and perfect master of his temper. In the conspiracies against his authority and person he often showed both justice and clemency. He excelled in the private virtues of chastity and temperance; his meals were short and frugal: on solemn fasts he contented himself with water and vegetables, and he frequently passed two days and as many nights without tasting any food. He allowed himself little time for sleep, and was always up before the morning light. His restless application to business and to study, as well as the extent of his learning, have been attested even by his enemies ('Anecdota,' c. 8, 13). He was or professed to be a poet and philosopher, a lawyer and theologian, a musician and architect; but the brightest ornament of his reign is the compilation of Roman law [JUSTINIAN'S LEGISLATION] which has immortalized his name. Unfortunately his love of theological controversy led him to interfere with the consciences of his subjects, and his penal enactments against Jews and heretics display a spirit of mischievous intolerance which has ever since afforded a dangerous authority for religious persecution.

Justinian died at eighty-three years of age, on the 14th November, 565, leaving no children, and was succeeded by his nephew Justinus II. (Ludewig, *Vita Justiniani Magni;* Gibbon, ch. xl.-xliv.)

Coin of Justinian.
British Museum. Actual Size.

JUSTINIANUS II., son of Constantine III., a lineal descendant of the Emperor Heraclius, succeeded his father on the throne of Constantinople, A.D. 685. His reign, which lasted ten years, was marked chiefly by wars with the Saracens, and by the exactions and oppressions of his ministers. At last his general Leontius drove him from the throne, had his nose cut off, and banished him to the Crimea, A.D. 695. Leontius however was soon after deposed himself and banished by Tiberius Apsimerus, who reigned for seven years. Meantime Justinian had escaped from the Crimea, and married the daughter of the Kakan, or king of the Gazari, a tribe of Turks; and he afterwards, with the assistance of the Bulgarians, entered Constantinople, and put to a cruel death both Leontius and Tiberius, with many others. He ordered also many of the principal people of Ravenna to be put to death. At last Justinian was dethroned and killed by Philippicus Bardanes, A.D. 711.

JUSTI'NUS I., by birth a peasant of Dacia, in his youth enlisted in the guards of the emperor Leo I. Under that and the two following reigns Justin distinguished himself by his military services, and gradually attained the rank of tribune, count, general, and lastly the command of the guards, which he held when the emperor Anastasius died, A.D. 518. He was then proclaimed emperor by the soldiers, being sixty-eight years of age, and the clergy and people approved the choice. Justinus, being himself uninformed in civil affairs, relied for the despatch of the official business of state on the quæstor Proclus, a faithful servant, who was also the friend of Justinian, Justin's nephew, who himself had acquired a great ascendency over his uncle. By Justinian's advice a reconciliation was effected between the Greek and the Roman churches, A.D. 520. The murder of Vitalianus, who had been raised to the consulship, but who, having excited the suspicion and jealousy of the court, was stabbed at a banquet, casts a dark shade upon the character of both Justin and Justinian. In other respects Justin is represented by the historians as honest and equitable, though rude and distrustful. After a reign of nine years, being afflicted by an incurable wound, and having become weak in mind and body, Justin abdicated in favour of his nephew, and died soon after, in A.D. 527.

JUSTINUS II., nephew of Justinian I., by his mother Vigilantia, was raised to the throne by the senators and the guards immediately after the death of his uncle, on the 15th November, A.D. 565. Soon after complaints reached Constantinople from the Romans against Narses the conqueror of the Goths, and exarch of Ravenna, whose great qualities were stained with avarice, and whose government had become unpopular in Italy. A new exarch, Longinus, was appointed to supersede Narses, and the empress Sophia, Justin's consort, added to the letters of recal the insulting message, that the eunuch Narses should leave to men the exercise of arms and the dignities of the state, and return to his proper place among the maidens of the palace, where a distaff should be placed in his hand. To this insult Narses is said to have replied, 'I will spin her such a thread as she will not easily unravel;' and he is said to have invited the Longobards, and their king Alboin, to invade Italy. However this may be, Alboin invaded Italy by the Julian Alps, A.D. 568, and in a few years all North Italy was lost to the Byzantine emperor. The provinces of Asia were likewise overrun by the Persians. Internal discontent prevailed in the capital and provinces, owing to the malversations of the governors and magistrates, and Justin himself, deprived by infirmity of the use of his feet, and confined to the palace, was not able to repress abuses and infuse vigour into the administration. Feeling at last his impotence, he resolved on abdicating the crown, and as he had no son, he chose Tiberius, the captain of his guards, as his successor. The conduct of Tiberius fully justified Justin's discernment. Justin lived four years after his abdication, in quiet retirement, and died in the year 578.

Coin of Justinus I. or II.
British Museum. Actual Size.

JUSTI'NUS, commonly called JUSTIN, MARTYR, one of the early fathers of the Christian church, and considered one of the ornaments of the body of men who professed the Christian faith in the times of its great discouragement while it was making head against the power of the Gentile world.

He was born in Palestine, at a place then called Neapolis, a new city, as may be inferred from its name, which had arisen near the antient town of Sichem, of which we read in the Old Testament, if it were not Sichem itself with a new name. His father was a Greek. Justin was carefully instructed in the learning of the Grecian schools of philo-

sophy, in the course of his studies visiting Alexandria, then a celebrated seat of learning; and travelling much in Egypt. With a mind deeply embued with the Platonic philosophy, he became sensible to the truth and beauty of Christianity, and made a public profession that he received it as divine truth. This was about the year A.D. 132.

During the remainder of his life he continued in the profession of Christianity, and is distinguished among the fathers of the church by the apologies and defences which he published. His first apology for Christianity was addressed to the emperor Antoninus, at a time when the Christians were suffering rather from popular fury than from the bearing upon them of the regular authority of the state, and it prevailed so far as to obtain for them some favourable concessions from the emperor. His second apology was addressed to the successor of Antoninus, Marcus Aurelius, on occasion of several Christians having been put to death for their faith. Both these apologies are extant; as well as another work of Justin's, which is a dialogue with Trypho, a learned Jew, in defence of Chistianity. Of the genuineness of these works there is no doubt. There is also another work of his 'On the Unity and Sovereignty of God;' but great suspicions are entertained of the genuineness of some other writings which have been attributed to him.

We have now to relate his end. The usual place of his residence was Rome, where, in or about A.D. 164, he was put to death a martyr to Christian truth. It was eminently as a martyr or witness that he suffered; for he might have saved his life had he consented to join in a sacrifice to the heathen deities. Hence with his name has descended the addition of The Martyr, a distinction which in a later age was given to Peter, one of the Protestant sufferers for the truth.

'The Dialogue with Trypho' was edited by Dr. Samuel Jebb, and the 'Apologies' by Dr. Charles Ashton, two learned Englishmen of the last century. Among the best editions of the whole works of Justin may be named that of Stephens, folio, 1551, and that of Oberthür, 2 vols. 8vo., 1777. There are English translations of the Apologies by William Reeve, M.A., 2 vols. 8vo., 1809; and of the Dialogue by Henry Brown, M.A., 1755.

Middleton in his 'Free Inquiry' has various remarks on this father, whose intellectual character and acquirements he rates very low (p. 27, &c).

JUSTI'NUS, the historian, is supposed to have lived under Antoninus Pius, as it would appear from the preface to his History, which he addresses to that emperor. The passage in which the emperor's name occurs is found in the older editions, but its authenticity is disputed. Nothing else is known of his personal history. He compiled an abridgment or epitome of the Universal History of Trogus Pompeius, who lived in the time of Augustus, and which consisted of forty-four volumes, as Justin tells us in his preface. The work of Trogus is unfortunately lost, except the prologi or heads of contents of each book, from which it appears that Justinus has been at times a careless abbreviator, having entirely omitted several interesting subjects which were treated by Trogus, such as in book i., the account of the Æolian and Ionian cities in Asia, of the origin of the Tusci or Etrusci in Italy, and of the cities of Egypt. Another charge against Justinus is the confused order in which he has narrated events, but this fault may be ascribed to the text of Trogus. Book i. treats of the Assyrians from Ninus to Sardanapalus, and of the Medians, Lydians, and Persians to Darius Hystaspes. The next five books are occupied by the history of the Greek and Persian wars; but by far the largest part of the work, from book vii. to book xvii. inclusive, is engrossed by the history of the Macedonian kingdom and empire, before and after Alexander. Books xviii. to xxiii. treat of Carthage and Sicily; books xxiv. to xl. treat of Greece, Macedonia, Asia, and Egypt, under the successors of Alexander down to the Roman conquest; books xli. and xlii. treat of the Parthians; book xliii. treats of the origin of Rome and of Massilia (Marseille); and the last book is upon the history of Spain. Book xxxvi., in which the author speaks of the Jews, has been commented upon by J. J. Schudt, in his 'Historiæ Judaicæ ex Gentilium Scriptis Collectæ,' 8vo., Frankfort, 1700. Among the best of the numerous editions of Justinus may be mentioned that by Abr. Gronovius, with variorum notes and dissertations, 1719, reprinted in 1760; that of J. G. Græveius, Leyden, 1683; that of the Bipontine Society, 1802; and that of Wetzel, 1806.

JUTES, an old Teutonic or Scandinavian tribe which in the fifth century of our æra appear as being settled in the northern part of the Chersonesus Cimbrica, which is still called, after their name, Jutland. Mannert (*Geographie der Griechen und Römer*) thinks that they were a colony from the opposite coast of Scandinavia, of the same race as the Guthi, or Gutæ, mentioned by Ptolemy. [GOTHS.] The first Germanic invaders of Britain after the departure of the Romans were Jutes, who, under their leaders Hengist and Horsa, A.D. 455, landed in the Isle of Thanet and settled in Kent. The Saxons under Ella came A.D. 477, and the Angles did not come till the following century. [ENGLAND.]

JUTLAND is the name of a large province of the kingdom of Denmark. The name was formerly given to the whole of the peninsula, which constitutes the continental portion of the kingdom. At present the name is restricted to the northern half, which is sometimes called North Jutland, the Duchy of Schleswig being considered as South Jutland. North Jutland is situated between 55° 20′ and 57° 42′ N. lat. and 8° 6′ and 10° 50′ E. long. Its form as far as 55° 12′ is a pretty regular parallelogram lying nearly due north and south: the northern part is almost a right angled triangle. The extreme length is about 170 miles; the breadth of the parallelogram varies from 70 to 85 miles, but in the centre it is 100 miles, the district of Kalloe projecting towards the east. It is bounded on the west and north by the German Ocean, on the east by the Cattegat and the Little Belt, and on the south by Schleswig. The area is 9408 square miles, and the population about 525,900. Few countries have such an extensive line of coast in proportion to their area as the Danish peninsula, which, especially on the more elevated east coast, is indented with numerous bays and inlets, and no town is above 45 miles from the sea. The most considerable of these inlets, the Lymfiord, extends across the peninsula. The entrance is on the east side, in lat. 57° and long. 10° 10′ E. It runs west to about 9° 20′, where it suddenly expands, forming as it were a large lake, stretching in a south-west direction to 56° 30′, where it turns to the north-west and reaches 56° 45′, the whole length being about 100 miles. It contains numerous islands, the largest of which, called Mors, situated in the broad part, has an area of 136 square miles and a population of 7800 inhabitants. In the year 1825 the North Sea broke through the narrow strip of land which separated it from the Lymfiord, and the breach being gradually enlarged, the northern part of Jutland is now a complete island. The apparent advantage of this extensive line of coast is much diminished by the shallowness of the sea, and the innumerable little islands, sandbanks, and shoals which render access difficult. The north coast, besides an immense range of sandbanks rising almost to the surface of the water, is rendered dangerous to navigators by numerous currents and the shortness and rapidity of the waves. The west coast, facing the German Ocean for above 200 miles, is bordered by a narrow strip of moving sand and a chain of sand-hills, within which there are many good pastures. The southern part of the west coast is alluvial soil, extremely fertile, but swampy and unhealthy, and requiring dikes to protect it from the inroads of the German Ocean, which however sometimes breaks through them, as happened in 1634, when 15,000 persons perished. The east coast is more elevated, rising in chalk-cliffs above the sea, and to the south of Aarhuus it presents a series of fertile and well-cultivated eminences. The province in general is very deficient in natural beauties. The only elevations are a range of low hills, seldom rising above a few hundred feet: they are the prolongation of the chain which runs through Mecklenburg and Holstein, and thence extends through the whole peninsula, terminating at its extreme northern point, the promontory of Skagen. Only the Himmelsberg attains the height of 1200 feet. The rivers are very small, and are all called 'aae;' the largest are, the Scholmaae, Widaae, Bredeaae, and Ribsaae. With respect to the soil, 5426 square miles are arable land, 2719 heath, 715 meadows and marshes, 313 forests, and about 235 tracts of moving sand. The productions are corn (more than sufficient for the inhabitants), hemp, flax, tobacco, and some timber. In the tenth and eleventh centuries the country was covered with vast forests, and there are still considerable woods of oak, fir, beech, &c. on the east coast, but on the west there are only willow, beech, and alder. The horses are large, but fitter for draught than for riding. The breed of black cattle is good,

and numbers of them and of hogs are exported to Holstein. There is abundance of game, and some wild boars are still found in the forests. The lakes, gulfs, and bays afford an inexhaustible supply of fish. The climate, through the proximity of the sea, is more temperate than might be supposed from the latitude. It is very variable, with frequent fogs and rains; the winters are not very rigorous, but the summer is often extremely hot. The inhabitants are in general illiterate, credulous, and indifferent to improvement. Till the ninth century the Jutes, from whom the country has its name, were governed by their own princes, two of whom, Gotice and Hemming, carried on war with Charlemagne. In the second half of the ninth century the country was conquered by Gormo Gammut, king of Denmark, who annexed it to his own dominions.

The peninsula is divided into four large districts called *stifts*, in this instance equivalent to diocese or bishopric:—Aalborg in the north, Aarhuus in the east, Wiborg in the centre, and Ripen in the south and west. The first two have been already described. Wiborg has an area of 1050 square miles and 85,000 inhabitants. The capital, of the same name, is situated on a small lake nearly in the centre of the peninsula, and has 4000 inhabitants. It is about 2¼ miles in circuit, is surrounded with ramparts, has six gates, and is pretty well built. There are a cathedral and two other churches, and a few manufactories. The bishopric of Ripen, or Ribe, the most extensive of all, has an area of 3842 square miles, but is in proportion the least populous, having only 150,000 inhabitants. Ribe, the capital and seat of the bishop, is a small walled town with 3000 inhabitants. It is situated on a little river called the Ribsaae, two miles from the German Ocean. Only small vessels can come up to the town, which has some trade in corn, oxen, and horses. There is one church besides the cathedral, and the oldest Latin school in Denmark (founded in 1248), with a library. Fredericia, the only fortress in Jutland, is in this diocese; it is situated on the Little Belt, has 4700 inhabitants, a Calvinist, a Roman Catholic, and two Lutheran churches, a synagogue, a custom-house for ships passing through the Little Belt, and other public buildings, and several manufactories.

JU'VENAL. Of the personal history of this great poet scarcely anything appears to be certainly known. His name is variously written Decius, or Decimus, Junius Juvenalis. His birthplace, on no very sure ground, is said to have been Aquinum, a Volscian town; and he is said to have been born somewhere about A.D. 40, under Caligula, and to have died, turned of 80, under Hadrian. He was of obscure extraction, being the grandson of an enfranchised slave. Some of his biographers say that he followed the profession of a pleader. He was intimate with the poet Martial. (Martial's *Ep.*, vii. 24, 91; xii. 18.) It does not appear that he gained any reputation until the publication of his Satires, which was late in life, after he was turned sixty. Still later he was sent in command of a cohort of infantry to Egypt, where he died from vexation and weariness of this honourable exile, which it is said was inflicted upon him as a punishment for satirizing a favourite of Hadrian under the person of Paris, the favourite actor of Domitian. See *Sat.* vii. 88, where Paris is described as the bestower of military patronage.

The relative merits of Juvenal and Horace as satirists have been warmly contested. It is a question on which men will form opposite opinions, as their tempers are more fit to relish brilliancy and playfulness, or earnest and dignified declamation. Juvenal is said to have spent much time in attendance in the schools of the rhetoricians, and the effect of this, in an age not remarkable for purity of taste, may be observed perhaps in a tendency to hyperbolical inflation, both of thought and style, which would soon betray a writer of less power into the ridiculous. From this his wit, command of language, and force and fullness of thought, completely preserve him: still perhaps he would produce more effect if the effort to do his utmost were less apparent. Dryden says, 'Juvenal gives me as much pleasure as I can bear. He fully satisfies expectation; he treats his subject home. His spleen is raised, and he raises mine: I have the pleasure of concernment in all he says. He drives his reader along with him, and when he is at the end of his way I willingly stop with him. If he went another stage it would be too far, and turn delight into fatigue. When he gives over 'tis a sign the subject is exhausted, and the wit of man can carry it no farther. If a fault can justly be found in him, 'tis that he is sometimes too luxuriant, too redundant.' His writings are addressed to the encouragement of virtue not less than to the chastisement of vice; and parts of them have been recommended by Christian divines as admirable storehouses of moral precepts. Still they lie open to the objection of descending so minutely into the details of vice as to minister food as well as physic to the depraved mind. To the scholar they are invaluable for the information which they supply concerning private life among the Romans. The editions of Juvenal are very numerous; that of Ruperti has (in England at least) nearly superseded others: it is attended by a copious body of explanatory notes, which are much needed in reading this difficult author. He is translated into English by Holiday, Dryden (who however only translated five satires of the edition which bears his name), Gifford, and Hodgson. The French prose translation of Dusaulx is highly praised. [DRYDEN; GIFFORD.] (*Proemium to* Ruperti's *Juvenal; Dedication to* Dryden's *Juvenal.*)

JYENAGUR, or JEYPORE, a principality in Rajpootana, lying between 26° and 28° N. lat., and between 75° and 78° E. long. On the west it is bounded by the British possessions in the same province, and on all other sides is contiguous to other Rajpoot territories. The surface of the country is in general level; the hills do not in any case acquire the size of mountains. The soil is for the most part sandy and arid, and in many places is strongly impregnated with salt, a considerable quantity of which is manufactured both for home use and for exportation. During the dry season, from February to July, the heat is excessive, and the clouds of hot sand which are driven about by the wind are so annoying as nearly to prevent travelling, and confine the inhabitants as much as possible within their dwellings. The cultivated fields are watered by means of wells, there being no permanent streams, and those produced by the rains being of little use for the purpose of irrigation during the dry season. The principal articles of produce are cotton, tobacco, and wheat, with some smaller grains. Cattle are reared for draught, and sheep for their wool. Jyenagur is more populous than most of the other Rajpoot states, and contains numerous forts in every part of the country; a great proportion of the villages also are defended by walls, and surrounded by ditches, notwithstanding which the inhabitants formerly suffered so severely from the incursions of plunderers, that so recently as 1819 the country had the appearance of being an extensive waste, in which large herds of cattle and of deer roamed about without restriction. Since that time a state of greater security has prevailed, cultivation has been resumed, the population has increased, and the public revenue, which had been almost annihilated through the general disorganization, now yields about 800,000*l.* per annum.

Jeypore, the capital, is situated in 26° 54′ N. lat. and 75° 38′ E. long., about 156 miles south-west from Delhi. The town is placed in a valley open to the south, and is surrounded by a wall of grey stone; it is well and regularly built, with four principal streets, which meet in a large square. The houses are three or four stories in height, and many of them are decorated with paintings in *fresco*, sculptures, porticoes, and other ornamental works executed in marble. Most of the dwellings are separate and built at equal distances; they are connected by means of a low wall. The temples, although modern, are built in the purest style of Hindu architecture, and some of them are of large dimensions. The distance of this city from Agra is 136 miles; from Benares 515 miles; from Bombay 740 miles; from Calcutta 975 miles; and from Delhi 156 miles—all travelling distances.

INDEX TO THE LETTER J.

VOLUME XIII.

K

K has the same sound which C has before the vowels *a, o, u*. A reference to that consonant will therefore suffice for the power of the letter; its various forms may be seen in ALPHABET. Although this letter is now superfluous, it was not so when the characters of an alphabet were syllabic in power. Thus the letter *k* appears to have denoted at one time the syllable *ka*, while another character represented *ko*, and so on. Hence in the Greek and Hebrew alphabets the former was called *kappa, kaph;* the latter *koppa, koph*. This accounts for the fact, that in Latin the letter *k* was never used except before the vowel *a*, precisely as *q* is found only before *u*, and the Greek koppa only before *o*. Even our own alphabet seems to imply such a limit in the use of this consonant, when it gives it the name *ka*, not *ke;* though the latter name would better agree with *be, ce, de*, &c.

KABYLES. [ALGIERS, vol. i., p. 327.]

KAEMPFER, ENGELBERT, well known as a botanist, and still more as a traveller, was born the 16th of September, 1651, at Lemgo, in the principality of Lippe-Detmold, in Germany, where his father was rector of the church of S. Nicholas. He was sent successively to the schools of Hameln, Lüneburg, Hamburg, and Lübeck, in all which he was distinguished by his rapid progress in the antient languages, history, geography, and music. He was afterwards sent to the gymnasium of Danzig. He next studied at the university of Cracow, in Poland, for three years, and at Königsberg, in Prussia, for four years more. At the last-mentioned place he applied himself closely to the study of physic and natural history. From Prussia he went to Sweden, where the extent of his knowledge and his talents procured him very advantageous offers on condition of settling at Upsala; but his desire to see remote countries led him to decline the proposals, and he solicited and obtained the place of secretary to an embassy which was then going to Persia. The embassy passed through Moscow, Kasan, and Astrakhan, where they embarked for Persia, and landed at Nizabad, in Daghestan, on the western shores of the Caspian Sea. While they were waiting for their passports in the town of Shamaki, in Shirvan, Kaempfer made an excursion to the peninsula of Absheran: he was the first naturalist who visited this remarkable spot, its wells of naphtha, and its ever-burning fire, which he described in his 'Amœnitates Exoticæ.' In 1684 the embassy arrived at Ispahan, then the capital of Persia. The information which Kaempfer collected during a residence of two years at that place respecting Persia and its natural productions is embodied in his 'Amœnitates.' When the embassy returned to Europe in 1685 Kaempfer entered as surgeon into the service of the Dutch East India Company, and served in that capacity in the navy then cruising in the Persian Gulf. After a long illness at Bender Abassi, he sailed for Batavia in 1689, and in this passage visited most of the countries on the western shores of Hindustan. At Batavia he occupied himself chiefly with the natural history of the island of Java. In 1690 he set out from Batavia on his voyage to Japan, as physician to the embassy which the Dutch East India Company annually sent to the Japanese court. He embarked in the vessel which was to touch at the kingdom of Siam, and visited Judia, or Juthia, then the capital of that country. He remained at Nagasaki, in Japan, from September, 1690, to November, 1692, and during this time he accompanied two embassies to Yeddo. His observations on Siam and Japan are given in his great work entitled 'The History of Japan,' the original of which has never been published, but a translation was made from a copy in the possession of Sir Hans Sloane by J. G. Scheuchzer, and published in England in 2 vols. fol., 1727. Kaempfer returned from Japan to Batavia, which he left in 1693 for Amsterdam. In April, 1694, he took the degree of doctor of physic at the university of Leyden, and in the theses which he published on that occasion he showed that the *Agnus Scythica*, or *Barometz*, a pretended plant-animal, was nothing but a fiction he also describ[illegible] other remarkable objects, and among them the electrical eel. On his return to his native place his reputation soon procured him the honour of being appointed physician to his sovereign, a circumstance which brought him into extensive practice. This however was a loss to science. Of the various works which he designed to publish only his 'Amœnitates Exoticæ' appeared during his lifetime (in 1712). His 'History of Japan,' as already observed, appeared much later, and only in English, from which it was afterwards translated into German and French. He died on the 2nd of November, 1716, his health having been much impaired by his travels and some domestic calamities. If we consider the variety, extent, and accuracy of the information contained in Kaempfer, we may confidently place him at the head of those naturalists who, more than any other class of travellers, have enlarged our knowledge of natural history and geography, and he may be considered as the precursor of Tournefort, Pallas, Sir Francis Hamilton, and Alexander von Humboldt.

(Scheuchzer's *Life of Kaempfer*, in his translation of the *History of Japan*.)

KÆMPFE'RIA, a small genus of Indian Scitamineæ, or Zingiberaceæ of some authors, of which the species are indigenous to the islands of the Archipelago and the southern parts of the continent of India, as Bengal and the districts on its eastern frontier. All are furnished with tuberous roots like the turmeric and ginger plants. The spikes of the flowers are short and rising from the root, in some species before, in others with, and nestled among the leaves: all are highly ornamental, and *K. rotunda*, called by the natives *bhooi chumpa*, or *ground chumpa*, is much cultivated in gardens on account of the beauty and fragrance of its flowers. It was supposed to yield the round Zedoary of the shops, but incorrectly as Dr. Roxburgh thinks, since he considers his *Curcuma Zedoaria* to be the plant. So *K. Galanga* was, equally incorrectly, long supposed to yield the Galanga of the shops. [GALANGA.] It is a native of the mountainous districts beyond Chittagong, and there called *Kumula*, and is cultivated by the Mugs; by them it is sold to the people of Bengal, who use it as an ingredient in their betel. The roots possess an agreeable fragrant smell, and a somewhat warm, bitterish, aromatic taste. The Hindus use them, according to Dr. Roxburgh, not only as a perfume, but also medicinally. The roots of *K. angustifolia* are, according to the same authority, used as a medicine for cattle by the people of Bengal.

KAFFA, called also Feodosia, is a town built on the south-eastern shores of the Crimea, in 45° 2′ N. lat. and 35° 20′ E. long., on a wide open bay, which is more than twenty miles across. The town stands on the most western angle of this bay, and its harbour is protected by a projecting cape. In antient times the town was called Theodosia, and was one of the towns of the Greek kingdom of the Bosporus. [BOSPORUS.] According to the author of the 'Periplus of the Euxine' it was a Milesian colony. Its importance appears to date from the time of Leucon, the contemporary of Demosthenes, who made it a port, and gave certain advantages to Athenian ships which came there for the purpose of carrying grain back to Athens. According to the author of the Periplus (who probably lived in the second century of the Christian æra), it was then called Ardauda in the Alan or Tauric dialect, which name signifies 'the seven gods.'

In the middle ages it seems to have been a considerable place, but especially so between the twelfth and fourteenth centuries, when it was in possession of the Genoese, who carried on a considerable commerce with India through Persia from this town. In 1474 it was taken from the Genoese by the Turks, but still continued a considerable place, though its population had decreased from 80,000, which it is stated to have had when the commerce of the Genoese was most flourishing, to 20,000 individuals. The wars which the Russians, in the latter half of the last century, carried on in these parts, ruined Kaffa, and still more the emigrations

which took place when the Russians got possession of the town. Towards the end of the last century Pallas describes it as a heap of ruins, enclosed by strong and lofty walls, which were fortified by towers, at the distance of 20, 40, and 60 fathoms from each other. The space enclosed by these walls is an oblong square along the bay, more than an English mile in extent. Among its ruins Pallas observed a large mosque, which was then used as the chief guard-house. In this ruined state the town, whose population at present probably does not exceed 5000 souls, remained up to the year 1806, when Russia tried to raise it again by declaring it a free harbour, and by establishing a quarantine, an assurance company, a botanic garden, a museum of antiquities, which are frequently found in the neighbourhood, a library, &c.; but the effect of these efforts seems not to have been great, for in 1830 the exports did not exceed 1,148,288 rubles, nor the imports 890,910 rubles, in paper money. Fishing is the principal occupation of the inhabitants. In its neighbourhood are oysters. Caviar is made here, as well as a small quantity of tobacco. It exports a great quantity of salt.

(Pallas, *Travels through the Southern Provinces of Russia;* Jones's *Travels in Norway, Sweden, Finnland, &c.;* Lyall's *Travels in Russia, the Crimea, &c.;* Demosthenes, *Leptin.*, c. 9; Strabo, vii., pp. 309, 311; Steph. Byzant. *Θευδοσία.*)

KAHIRA, or CAIRO, more properly *El Ckáhireh*, which was its former name, but now called by the natives *Musr*, the capital of modern Egypt, is situated in 30° 5′ N. lat. and 31° 20′ E. long., in a plain midway between the right or eastern bank of the Nile and the ridge of Mokattam, and near the apex of the Delta of the Nile. The tract of land between the town and the river, which is above a mile in width, in the direction of Boolak, the northern harbour of Kahira, becomes narrower farther south, so as to be less than half a mile wide, in the direction of Musr el Ateeckah, the southern harbour or landing-place. Kahira occupies about three square miles; it is surrounded by a wall, the gates of which are shut at night, and is commanded by a large citadel situated at an angle of the town, on one of the lower elevations of the contiguous ridge, in which is the residence of the Pacha. The streets of Kahira are unpaved, irregular, and narrow; they are more like lanes than streets. The great thoroughfare streets have generally a row of shops on each side. Above the shops are apartments which do not communicate with them, and which are inhabited by private families. Most of the bye-streets have a wooden gate at each end, closed at night, and guarded by a porter within, who opens it to persons who require admittance. There are also many courts with several narrow lanes branching out of them, but no thoroughfare, and only one common entrance, with a gate, which is also closed at night. The external walls of the better sort of houses are cased to the height of the first floor with the soft calcareous stone of the neighbouring mountain. The superstructure, the front of which generally projects about two feet, is of burnt brick of a dull red colour, but often plastered. The roof is flat, and covered with a coat of plaster. The ground-floor apartments next the street have small wooden grated windows; but the windows of the upper apartments are mostly formed of turned wood lattice-work, which is so close that it shuts out much of the light and sun, but admits the air. In the better houses the windows are furnished with frames of glass in the inside, which are closed in the winter, for a penetrating cold is felt in Egypt when the thermometer is below 60°. The houses in general are two or three stories high, and most of them enclose an open unpaved court, into which the principal apartments look. In the court is a well of slightly brackish water, which filters through the soil from the Nile; and on its most shaded side are commonly two water-jars, which are daily replenished with water of the Nile, brought from the river in skins.

There are in the town three or four squares or open places of considerable extent, two of which are overflowed during the high floods of the Nile. Among the numerous mosques, four are distinguished for their size and architecture—that of Tooloon, which dates from the ninth century of our æra; that of El Hakim; that of El Azhar, with a splendid dome, and a college attached to it; and lastly, the mosque of Hhasaneyn, with its high dome, its two lofty minarets, and its marble and other ornaments. Among the other remarkable buildings are the public baths, of which there are between sixty and seventy in the town, several of them very spacious, handsomely ornamented and painted, externally and internally, the various apartments being paved with marble. The coffee-houses, which are very numerous, are extremely plain and unadorned. There are in Kahira numerous buildings called wekalehs, for the accommodation of merchants and their goods. These buildings are square or oblong, having an open court in the middle, with vaulted warehouses for merchandise on the ground-floor opening into the court, and lodgings above them. The shops in the streets are small square recesses or cells, about six or seven feet high and between four and six feet wide, in which there is just room enough for the seller and one or two customers. The public gardens consist of groves of orange and lemon trees and vines; and the cemeteries, both within and without the town, are also frequented as promenades.

The population of Kahira is reckoned at 240,000 inhabitants, of whom about 190,000 are native Mussulmans, 10,000 Copts, between 3000 and 4000 Jews, and the rest strangers from various countries. The police maintained in the metropolis is tolerably strict: punishments are arbitrary but lenient; convicted malefactors are mostly employed in the public works.

In the neighbourhood of Kahira are, Boolak, with the custom-house, the bazaar, the printing-press, a school or college, some silk manufactories and about 18,000 inhabitants; Musr el Ateeckah, where the town of Fostat, or Old Kahira, once stood, and where the vast granaries are now seen; Schoobra, with a country-house and fine gardens of the Pacha; Aboo Zabel, where is a school of medicine, anatomy, and surgery, and a large military hospital, all created by the present Pacha Mehemet Ali. Nearly opposite Kahira, on the left bank of the Nile, are the great pyramids of Jizeh.

Kahira still maintains the reputation of being the best school of Arabic literature; and for Mohammedan theology and jurisprudence the fame of its professors remains unrivalled. Schools for children are very numerous at Kahira: almost every mosque has a koottab, or day-school, attached to it, in which children are instructed in reading the 'Koran,' and, if required, in writing and arithmetic. The schoolmasters are mostly persons of very little learning. Those youths who propose to devote themselves to religious employment or the learned professions pursue their studies in a great college attached to the mosque of El Azhar, which has a considerable library. Besides the study of grammar, rhetoric, and versification, lectures are given on logic, theology, the exposition of the Koran, and the traditions of the Prophet; on religious, moral, civil, and criminal law, which is chiefly founded on the Koran and the traditions; arithmetic and algebra, &c. The instruction is gratis. The number of students is about 1500, from almost all parts of the Mohammedan world. The Azhar has lost the greater part of its revenues, the Pacha having seized the cultivable lands belonging to the mosques. The professors subsist by teaching in private houses, copying books, and on the presents which they receive from the wealthy. Besides this college or university, there are, an elementary school of arts and sciences at Casr el Ain, a school of administration to instruct those who are designed for civil offices, and a school of artillery and engineering. The Arabic spoken by the middle and higher classes at Kahira, though inferior in grammatical correctness and pronunciation to that of the Beduins of Arabia, is much superior to that spoken in Syria, and still more to that of the Moghrabins, or Barbary Arabs. (Lane's *Account of the Manners and Customs of the Modern Egyptians;* Wilkinson; Minutoli; Planat, *Histoire de la Régénération de l'Egypte*, Paris, 1830.)

KAHAU. (Proboscis Monkey.) [NASALIS.]

KAKOXENE, a mineral occurring in small crystals, which appear to be six-sided prisms terminated by pyramids, disposed in radiating tufts. Colour yellow of several shades, and sometimes brownish-red. Lustre silky, sometimes adamantine; adheres to the tongue, and has an earthy smell.

When placed on a hot coal it emits a green phosphoric light, and before the blowpipe on charcoal decrepitates: with borax forms a deep green-coloured glass, and with soda a blackish mass.

It occurs in clayey brown iron-stone at Zbirow, in Bohemia.

Analysis by Steinman:—

Phosphoric acid	17·86
Fluoric acid and water	25·95
Peroxide of iron	36·82
Alumina	10·01
Silica	8·90
Lime	0·15
	99·69

KALENDAR, a register or distribution of the year, accommodated to the uses of life; containing the order of days, weeks, months, festivals, &c., as they occur in the course of the year. It is so called from the *kalendæ*, or Kalends, which among the Romans denoted the first day of every month. The kalendar, being of civil institution, varies according to the different distributions of time in different countries. Those which we shall take more particular notice of are, the Roman, the Julian, the Gregorian, and the Reformed Kalendar: a slight mention of the others will be sufficient.

Romulus, according to tradition, formed what is deemed the original Roman kalendar, by which the year was divided into ten months only, consisting of an unequal number of days, and began with March. The total number of days was 304. It was however soon discovered that the civil year, as thus constituted, was much shorter than the solar year. Romulus therefore added two intercalary months to every year; but these months were not inserted in the kalendar, nor were any names assigned to them until the following reign. Some Roman antiquarians maintained that the old kalendar continued in use till the time of Tarquinius Priscus.

Numa, in imitation of the Greeks, divided the year into twelve months, according to the course of the moon, consisting in all of 354 days: according to Pliny (*Hist. Nat.* xxxiv. 7), he afterwards added one day more to make the number odd, which was thought a more fortunate number. But as ten days, five hours, forty-nine minutes (or rather forty-eight minutes fifty-eight seconds) were wanting to make the lunar year correspond to the course of the sun, he intercalated every other year an extraordinary month, called *Mensis intercalaris*, or *Mercedonicus*, between the 23rd and 24th of February. This month appears to have consisted alternately of 22 and 23 days during periods of 22 years, the last biennium in the 22 years being entirely passed over. The intercalation of this month was left to the discretion of the pontifices, who, by inserting more or fewer days, used to make the current year longer or shorter, as was most convenient for themselves or their friends; for instance, that a magistrate might sooner or later resign his office, or contractors for the revenue have longer or shorter time to collect the taxes. In consequence of this licence the months were transposed from their proper seasons; the winter months carried back into autumn, and the autumnal into summer. Some critics are of opinion that there is a reference to this confusion in one of Cicero's letters to his friend Atticus (x. 17).

Julius Cæsar, when he had made himself master of the state, resolved to put an end to this disorder, by abolishing the use of the intercalations; and for that purpose, B.C. 47, adjusted the year according to the course of the sun, and assigned to the months the number of days which they still contain. He also added an intercalary day to February every four years. [BISSEXTILE.] To make everything proceed regularly, from the 1st of the ensuing January, he inserted in the current year, besides the intercalary month of 23 days, which fell into it, two extraordinary months between November and December, the one of 33, the other of 34 days; so that this year, which was called the last year of *confusion*, consisted of fifteen months, or 445 days. (Sueton., *Vit. J. Cæs.*, c. 40.) These 67 days were inserted in order to set the year right, which was 67 days in advance of the true time.

All this was effected by the care and skill of Sosigenes, an astronomer of Alexandria, whom Cæsar had brought to Rome for that purpose; and a new kalendar was formed from his arrangement by Flavius, digested according to the order of the Roman festivals, and the old manner of computing the days by kalends, nones, and ides, which was published and authorised by the dictator's edict.

This is the *Julian* or Solar year, which continues in use to this day in all Christian countries, without any other variation than that of the *old* and *new style*, which was occasioned by a regulation of Pope Gregory XIII., A.D. 1582, who, observing that the vernal equinox, which at the time of the council of Nice, A.D. 325, had been on the 21st of March, then happened on the 10th, by the advice of astronomers caused ten days to be thrown out of the current year, between the 4th and 15th of October; and to make the civil year for the future to agree with the real one, or with the annual revolution of the earth round the sun, or, as it was then expressed, with the annual motion of the sun in the ecliptic, which is completed in 365 days, 5 hours, 49 minutes, he ordained that every 100th year should not be leap-year; excepting the 400th; so that the difference will hardly amount to a day in 7000 years, or, according to a more accurate computation of the length of the year, to a day in 5200 years.

This alteration of the style was immediately adopted in all Catholic countries; but not in Great Britain till the year 1752, when eleven days were dropped between the 2nd and 14th of September, so that this month contained only nineteen days; and thenceforth the new or reformed style was adopted, as it had been before in the other countries of Europe. The same year also another alteration was made in England, by which the legal year, which before had begun on the 25th of March, began upon the 1st of January; this alteration first took place on the 1st of January, 1752. (See the Statute, 24 Geo. II., ch. 23.) By this statute it was also enacted that the several years of our Lord 1800, 1900, 2100, 2200, 2300, or any hundreth years of our Lord which shall happen in time to come, except only every fourth hundredth year of our Lord, whereof the year 2000 shall be the first, shall not be deemed bissextile or leap-years, but shall be considered as common years, consisting of 365 days only; and that the years of our Lord 2000, 2400, 2800, and every other fourth hundredth year of our Lord from the year 2000 inclusive, and also all other years of our Lord which, by the present computation, are considered bissextile or leap-years, shall, for the future be esteemed bissextile or leap-years, consisting of 366 days: and that whereas according to the rule then in use for calculating Easter-day, that feast was fixed to the first Sunday after the first full moon next after the 21st of March; and if the full moon happens on a Sunday, then Easter-day is the Sunday after; which rule had been adopted by the general council of Nice; but that as the method of computing the full moons then used in the church of England, and according to which the table to find Easter prefixed to the book of Common Prayer is found, had become erroneous, it was enacted that the said method should be discontinued, and that from and after the 2nd of September, 1752, Easter-day and the other moveable and other feasts were henceforward to be reckoned according to the kalendar tables and rules annexed to the act, and attached to the books of Common Prayer.

It is not generally known that an effort was made to reform the kalendar in England, as early as the reign of Queen Elizabeth. On the 16th of March, 27 Eliz., A.D. 1584-5, a bill was read the first time in the House of Lords, entitled 'An Act giving Her Majesty authority to alter and new make a Kalendar according to the Kalendar used in other Countries.' It was read a second time on the eighteenth of that month, after which no notice occurs of the proposed measure.

The formation of the *Hebrew* kalendar is fixed by some to the same year as the council of Nice, A.D. 325: others have placed it in the year 360; and others as late as A.D. 500. Lindo however assures us that the Mishna compiled according to the Jewish account in the year A.D. 141 proves that the kalendar as used by the Jews in its present form, with the intercalary month, was generally known and followed at that time. For further information upon the Jewish kalendar the reader may consult Dr. Adam Clarke's *Commentary upon the Bible*, and Lindo's *Jewish Calendar*.

Two *Kalendars* are *in use in the East*: the Arabian, which is common to all the Mohammedan countries; and the Persian, the use of which is peculiar to that country. This last is founded on the Persian æra called 'Yezdegird.'

The last we shall mention is the *French Revolutionary Kalendar*. In September, 1793, the French nation resolved that the republic should form a new æra, and that a kalendar should be adopted on what were termed philosophical principles. The Convention therefore decreed, on the 24th of November, 1793, that the common æra should be abolished in all civil affairs: that the new French æra should com-

mence from the foundation of the republic, namely, on the 22nd of September, 1792, on the day of the true autumnal equinox, when the sun entered Libra at 9h 18 30s in the morning, according to the meridian of Paris; that each year should begin at the midnight of the day on which the true autumnal equinox falls; and that the first year of the French republic had begun on the midnight of the 22nd of September, and terminated on the midnight between the 21st and 22nd of September, 1793. To produce a correspondence between the seasons and the civil year, it was decreed, that the fourth year of the republic should be the first sextile, or leap-year; that a sixth complementary day should be added to it, and that it should terminate the first Franciade; that the sextile or leap-year, which they called an olympic year, should take place every four years, and should mark the close of each Franciade; that the first, second, and third centurial years, namely, 100, 200, and 300 of the republic, should be common, and that the fourth centurial year, namely, 400, should be sextile; and that this should be the case every fourth century until the 40th, which should terminate with a common year. The year was divided into twelve months of thirty days each, with five additional days at the end, which were celebrated as festivals, and which obtained the absurd name of 'Sansculottides.' Instead of the months being divided into weeks, they consisted of three parts called Decades, of ten days each. It is however to be observed that the French republicans rarely adopted the decades in dating their letters, or in conversation, but used the number of the day of each month of their kalendar.

The republican kalendar was first used on the 26th of November, 1793, and was discontinued on the 31st of December, 1805, when the Gregorian was resumed.

Of the three parts into which the Romans divided their month, the *kalendæ*, or kalends, have been already explained. They were so called (à *calando* vel *vocando*), from the pontifex calling out to the people that it was new moon. The fifth day of the month was called *Nonæ*, the nones, and the 13th *Idus*, the ides, from the verb *iduare*, to divide; because the ides nearly divided the month. The nones, from *nonus*, the ninth, were so called because, counting inclusively, they were nine days from the ides. In March, May, July, and October, the nones fell on the 7th and the ides on the 15th of the month. The mode of fixing any particular day was by saying that it was so many days before the kalends, nones, or ides, next immediately following. Thus the 28th of April was the 4th day before the kalends of March; the 4th of March was the 4th day before the nones of March; and the 9th of March was the 7th day before the ides of March.

The Attic year consisted of twelve lunar months of 30 and 29 days alternately: an intercalary month of 29 or 30 days was inserted every two years, but as this was 7½ days too much, the intercalary month was sometimes omitted. The full Attic month consisted of 30 days, and was divided into three decades.

On the subject of the Greek Kalendar the reader may consult Ideler, *Handbuch der Mathematischen und Technischen Chronologie*.

(Adams's *Roman Antiquities*; Niebuhr, *On the Secular Cycle, Hist. of Rome*; Brady's *Clavis Calendaria*; Sir Harris Nicolas's *Chronology of History*; Hutton's *Philosophical and Mathematical Dictionary*, v. *Calendar*; Lindo's *Jewish Calendar*, 8vo. Lond. 1838.)

KALENDÆ. [KALENDAR.]

KALI, the name of the maritime plant from the ashes of which soda is obtained by lixiviation; and from the name of this plant, with the Arabic article *al*, is derived that of a class of substances possessing peculiar properties. [ALKALI.] Kali was also formerly employed to designate the alkali potash. [POTASSIUM.]

KALMUCKS. [CALMUCKS.]

KALSEEPEE. [ANTELOPE, vol. ii., p. 83.]

KALU'GA, a government of European Russia, lies between 53° 24′ and 55° 21′ N. lat., and 33° 20 and 37° E. long. It is bounded on the west and north-west by Smolensk, on the north-east by Moscow, on the east by Tula, and on the south by Orel. Authors differ extremely respecting its area. Schubert and Stein make the area about 8500 square miles; others make it considerably more, and Soimonoff gives it at 12,530, which Hassel however thinks too much, and prefers Schubert's estimate. According to the maps before us, we should say between 11,000 and 12,000; its length being 150 miles, and the mean breadth 75. The population is stated in 1836 at 1,309,500. The face of the country is one unvarying level; here and there broken by a low hill or the wooded bank of a river. In every direction there is one boundless flat, consisting partly of corn-fields, partly of meadows and commons, and it is but seldom that a little enclosure or a group of wood interrupts the uniformity of this uninviting scene. The soil varies considerably, but for the most part is clayey and sandy; in parts there is stiff clay: rich black mould is rare. Of the eighteen rivers, the principal are the Oka, a branch of the Volga, which is navigable by barks all the year; the Uva, which flows into the government of Tula, but is here navigable by barks only when the water is high; the Shisdra, which falls into the Oka to the west of Kaluga; the Ugra, which in some places forms the boundary towards Smolensk, and united with the Wora joins the Oka; the Ressata and the Tarusa, which flow into the Oka, and which, like the Shisdra and Ugra, are used only for floating rafts of timber. The Bolwa continues its course to Orel. According to Storch there are eleven, and according to Georgi five small lakes, one of which, in the circle of Serpeisk, is five wersts in length and one in breadth. There are marshes in some parts. The rivers freeze about the end of November and thaw by the end of March. The soil, being on the whole indifferent, requires much care and abundance of manure to make it yield four or five-fold; in general the produce is but two or three-fold; common barley, which produces from five to eight-fold, is often mixed with rye for bread. It is only in favourable years that the province produces enough for its own consumption. Hemp and flax are staple products, affording a surplus for exportation. Horticulture is carefully attended to: the inhabitants of the towns, as well as of the country, have their kitchen-gardens, which yield not only ordinary vegetables and potatoes, but abundance of hops and apples; finer kinds of fruit and vegetables are confined to the gardens of the rich. The forests, having been better managed than in some other governments, yield plenty of timber for all purposes. Game and fish are not plentiful. The breeding of cattle is merely subsidiary to agriculture, and the number of cattle is very small; the breeding of horses alone is attended to. The mineral products are bog-iron, stone for mill-stones, lime, gypsum, and turf; though no mines are worked, there are several great iron-forges, where, besides a little of their own bog-iron, ore from the other provinces is smelted.

The inhabitants are active, very temperate, and in easy circumstances. The country-people, especially the women, are much engaged in spinning and weaving; the men are chiefly mechanics and shopkeepers; and many go for work into other provinces. The brandy distilleries are very considerable. The manufactures of coarse woollens, linen, sailcloth, calico, silk, velvet, ribbons, leather, paper, glass, are important, considering the backward state of the country in general, and pretty large quantities are exported. Of the natural productions very little can be spared for exportation. The inhabitants are all Russians of the Greek church, under the bishop of Kaluga. The nobility are very numerous.

KALUGA, the capital of the government, is situated in 54° 30′ W. lat. and 36° 5′ E. long., on the river Oka, which is here 200 yards wide. It is about six miles in circumference, surrounded with a rampart converted into a public walk, has narrow crooked streets, and for the most part wooden houses. There are some good buildings, such as the bishop's palace, the residence of the governor, and the principal church; and there are 23 stone churches, an ecclesiastical seminary, a convent of nuns, a gymnasium, several schools, a theatre, a foundling hospital, &c. The manufactories are considerable, and the export trade, which extends even to Danzig, Königsberg, Brody, and Leipzig, is very active. The exports are canvas, paper, hats, leather, cottons, and woollens; likewise hemp-seed, hemp, flax, linseed, honey, and wax. Population (1836) 32,345.

KAMICHI. [PALAMEDEA; RALLIDÆ; MEGAPODIDÆ.]

KA'MPEN, or **CAMPEN**, a town of the Netherlands, in the province of Overyssel,* in 52° 37′ N. lat. and 5° 48′ E. long., situated on the left bank of the Yssel, near its mouth in the Zuyderzee, where it divides into several arms, and forms the island of Kampen. It was built in the year 1286; the antient fortifications are in a very dilapidated

* By mistake a reference has been made to this article from DRENTHE.

state. It has two churches, and a wooden bridge over the Yssel 723 feet long and 20 feet wide. The inhabitants amount to 8900: they manufacture great quantities of blankets, plush, and felt; and carry on a salmon-fishery on the Yssel. The trade, which formerly was considerable, has declined in consequence of the port being much choked up with sand. The environs can be laid under water.

KAMTCHATKA, a peninsula projecting from the north-eastern parts of Asia into the Pacific, in a direction nearly due south, lies between 51° and 63° N. lat., and between 155° and 165° E. long. Its length is above 800 miles, and its width varies between 30 and 120 miles. Its area is stated to be about 86,000 square miles, or somewhat less than that of Great Britain.

Its southern extremity, Cape Lopatka, is a low and narrow tongue of land (51° N. lat.), which however widens as it proceeds northward, and gradually rises into mountains. The country south of 53° 5′ is covered with hills and mountains, which are rocky and barren, and only in some inconsiderable valleys clothed with creeping cedar, and willow and stunted birch. At about 53° 5′ N. lat. is a mountain-knot, whence issue two ranges, one running due north, and the other north-east. These ranges enclose the vale of the river Kamtchatka. The western range, which first runs nearly due north, declines afterwards to north-north-east, and in that direction traverses the whole length of the peninsula, joining north of it the eastern branches of the Aldan Mountains. It does not appear to contain high summits, and its mean elevation probably does not rise above the line of trees, which in this country is about 3000 feet above the sea. But the range running east of the river Kamtchatka is distinguished by several high summits, which are of volcanic origin, and most of them still active. The highest, from south to north, are the Awatchanskaja, which rises to about 9500 feet; the Tolbatchinskaja, which attains 8346 feet; the Kliootchewskaja, the highest of all, rising to 15,825 feet; and the Shiwelutchkaja, whose highest summit is 10,591 feet above the sea-level. These volcanoes constitute the northern extremity of that extensive series which encloses the eastern coast of Asia, and traversing the islands of Japan and the Philippines, probably has a connection with the other series of volcanoes which traverse the Sunda and Molucca islands from east to west.

The mountains approach close to the eastern coast, which is composed of high rocks, rugged cliffs, and bold promontories, forming numerous inlets, the entrances to which are blocked up by reefs of rocks. The mountains are mostly covered with trees, which grow to a considerable height towards the south, but diminish in size as we advance northward. Numerous rocks are scattered in the sea at a distance of from one to three miles from the shores; some of them are only discernible by the breakers, while others tower up to a considerable height. The depth of the sea varies considerably and suddenly from 30 to 90 fathoms and more. Earthquakes are frequent, and sometimes very violent.

The western shores along the Sea of Okhotzk, or, as it is now frequently called, the Sea of Tarakai, north of the mountain-knot, are uniformly low and sandy to a distance of about 25 or 30 miles inland. They produce only willow, alder, and mountain-ash, with some scattered patches of stunted birch, and towards the north they are almost entirely overgrown with rein-deer moss. The sea is shallow to a considerable distance, and the soundings very regular. The small rivers which traverse this region have at their mouth not more than six feet at low water, with a considerable surf breaking on the sandy beach.

The best part of the peninsula is the vale of the Kamtchatka river, which towards its southern extremity is 40 miles across, but grows narrower as it proceeds northward. Its length is 180 miles. Its soil is deep and rich, composed of a black earth, and exhibits a considerable degree of fertility.

Among the rivers, only the Kamtchatka requires notice. It rises on the northern declivity of the mountain-knot, runs in general in a northern direction through the vale, but at Nishnei Kamtchatka, where it approaches its northern extremity, it turns east, and empties itself in a large but shallow bay, which is only eight feet deep at high water, and in which the breakers are very violent when an easterly wind blows. It flows about 300 miles, and is the only navigable river in the peninsula.

The climate of Kamtchatka, when compared with that of Europe under the same latitude, is very severe, but it is much milder than the eastern districts of Siberia. The frost sets in about the 10th of October, but up to the middle of December the thermometer commonly varies between 23° and 27° Fahr. During the following months it averages between 14° and 20°. In very severe frost it descends to −10° and −15°, and sometimes, though rarely, to −25°. On the sea-coast vegetation does not begin before the end of April, but in the vale of the Kamtchatka, which is sheltered on all sides by mountains, it begins at the end of March. Rain is frequent in summer, and in winter a great deal of snow falls.

Agriculture was introduced more than 80 years ago. In some places on the western coast, but more extensively in the vale of the Kamtchatka river, rye, barley, buck-wheat, potatoes, white cabbages, turnips, radishes, and cucumbers are grown, but these articles are only cultivated by the Russian settlers. The number of horses and cattle is on the increase. The natives formerly lived chiefly on the produce of the chace, by hunting bears, wild sheep, or argalis, wild rein-deer, ermines, black, red and stone foxes, wolves, sables, sea-otters, and fish otters; but since the number of these animals has considerably decreased, their time and industry are employed in fishing. In no part of the globe is fish more abundant. The natives scarcely know any other kind of food, and the bears and dogs, wolves and foxes, sea-otters and seals, water-fowl and birds of prey of various sorts, all feed upon fish. The most numerous kinds are herrings, salmon, and cod. Wild-fowl, especially geese and ducks, are very numerous and easily taken, as also sea-fowl, some species of which are eaten; but their eggs are of more importance to the inhabitants, of which whole boats-full are easily collected. Poultry is very scarce on account of the dogs, who devour the fowls wherever they find them. Whales are numerous, but they are not taken.

The forests, which cover the eastern chain, contain many fine timber-trees, which are little used, but might be employed in ship-building. These forests contain chiefly birch, larch, fir, and cedar pine (*pinus cembra*). The mineral wealth is little known: in some places there is iron-ore, and sulphur in immense beds is found in the vicinity of the volcanoes.

Two native tribes inhabit the peninsula, the Kamtchadales and the Koriakes, the former occupying the peninsula as far as 58° N. lat. The Koriakes wander through the country north of that of the Kamtchadales. It is not certain whether both tribes belong to the same race of men, but the difference in their features is not great. The Kamtchadales are short, but stout, and broad in the shoulders. Their head is large, their face flat and broad, their cheek-bones are prominent, their lips thin and their nose flattened. Their hair is black, hard and lank, their eyes sunk in the head, and their legs thin. They evidently belong to the Mongol race. The Koriakes are principally distinguished from them by the smallness of their head. Both nations differ in language and in mode of life. The Kamtchadales are huntsmen and fishermen, have fixed habitations, and use dogs to draw their sledges in winter. The Koriakes are a wandering tribe, subsisting on the produce of their numerous herds of rein-deer, of which the richer among them frequently possess several thousands, and their sledges are drawn by these animals. This last-mentioned tribe is scattered over a considerable part of the country between the Sea of Okhotzk and the Polar Sea. The whole population of the peninsula is stated not to exceed 5000 souls, but it seems that the wandering Koriakes are not included in this estimate. The number of Russian settlers and their descendants is said to amount to 1400, a few Cossacks included. The remainder are Kamtchadales.

The principal place is now Pétropaulovski, built on an extensive bay [AWATSKA BAY], with about 600 inhabitants. Nishnei Kamtchatka, on the river Kamtchatka, formerly the residence of the governor, hardly contains more than 100 inhabitants. Bolcheresk has a small harbour on the western coast, and about 200 inhabitants.

The commerce of Kamtchatka is inconsiderable. It exports only the furs of several animals which are taken by the natives, and imports several articles of food, especially flour, and of luxury, as whiskey, &c. But during the last century it acquired a greater importance by becoming the place whence the Russo-American Company sent vessels to the north-west coast of America for the purpose of procuring furs and skins of several wild animals, which pass from Kamtchatka to Okhotzk and thence to Kiachta. Since the

re-establishment of peace in Europe, and the restitution of the island of Java, the Dutch have begun to send every year one or two vessels to Petropaulovski with rice, flour, brandy, sugar, coffee, cloth, &c., and these goods pass hence into the eastern districts of Siberia.

Kamtchatka is a Russian province annexed to the government of Eastern Siberia, or that of Irkutsk.

KANDAHAR, or CANDAHAR. [AFGHANISTAN.]

KANGAROO, KANGOOROO, or KANGUROO. [MARSUPIALIA.]

KANT, IMMANUEL, the author of the 'Critical Philosophy,' and distinguished as well for the profundity of his views as for the extent and variety of his researches, was born April 22, 1724, at Königsberg in Prussia, where he died on the 12th of February, 1804. His native city, to which he was so attached that in a long life of nearly 80 years he never left it long or for a great distance, was the scene of Kant's literary activity. Educated at its gymnasium, he removed in 1748 to its university to attend the classes of philosophy, mathematics, and theology. Upon the completion of his academical studies, Kant passed many years in the capacity of tutor, according to his own confession with little satisfaction to himself, since the desire of acquiring knowledge interfered with the duty of imparting it. In 1755 he passed to the degree of M.A., when he commenced a series of private lectures on logic and metaphysics, physics, and mathematics, which he continued to give for fifteen years, until he was invited, in 1770, to fill the chair of the former science, which he held until 1794, when his declining strength compelled him to resign its arduous and laborious duties.

The skill and success with which Kant attacked, with his able and searching criticism, the specious but false pretensions of the existing philosophy, gained him the name of the 'smasher,' or the 'destroyer' (*der zermalmende*), from those who pretended that he was more skilful in destroying than in reconstructing a system. At the time when Kant first entered directly into the arena of philosophy, its possession was disputed by a superficial eclecticism and uncompromising dogmatism on the one hand, and on the other by a bold unlimited doubt which was cherished by the refined and consequential scepticism of Hume's writings. To put an end to this state of things, which was as dangerous to the truths of morality and religion as it was subversive of the legitimacy of knowledge, was the object of Kant's philosophical labours; and for this purpose he sought to expel both dogmatism and scepticism from the domain of philosophy.

Kant accordingly proceeded to an examination of man's cognitive faculty, in order to discover the laws and extents of its operation. This investigation he designated the criticism of the pure reason, and held that the reason, as a pure faculty, must criticise not only itself, but also, as the highest activity of the human intellect, the subordinate faculties of sense and understanding. Kant understood by *pure* whatever is independent of experience, as opposed to the empirical, which rests upon it. The pure, or whatever in knowledge expresses the universal and necessary is *à priori*, that is, antecedent to experience; whereas all that is contingent or only comparatively general is *à posteriori*. The first requisite in philosophy is a science which may establish a possibility, and determine the principles and extent of such knowledge. Now it cannot be derived from experience, which only shows an object to us such as it appears to be, without declaring that it must be such as it is. All attempts to derive the necessary from experience are unsuccessful, simply because they contradict the consciousness which recognises an essential difference between necessary and contingent. Experience serves only as a stimulus to awaken the faculties of pure cognition, so that afterwards, by reflection and abstraction (*absonderung*), we become specially conscious of them. As then we are undoubtedly in possession of such pure or *à priori* knowledge, of which it is impossible to place the origin in experience, it must have its root in the pure reason itself, which, on the other hand, cannot be the ground of the contingent and empirical; for the pure reason contains nothing but the formal or necessary principles of all knowledge, whereas the objects to which these principles refer are given to the mind from without. As an instance of these universal and necessary principles, Kant adduces the law of causation, the speculations of Hume upon which afforded the occasion of his philosophical investigations. He observes that the notion of a cause so manifestly implies the necessity of its being connected with some effect, and enforces so strongly the universality of this law, that it is totally inconsistent with the derivation of it from the repeated association of an effect with an antecedent. The next point which Kant notices in the 'Introduction to Critic of the Pure Reason,' as of great importance for the right appreciation of his philosophical system, is the distinction between analytical and synthetical judgments. The former are those in which the predicate is connected with the subject by identity; the latter are devoid of all identity of the subject and predicate. Analytical judgments may be also termed explanatory, the synthetical extending (*erweiterungsurtheile*) judgments; since in the former the predicate adds nothing to the notion of the subject, and only resolves the notion which forms the subject into its constituent and subordinate notions, which however involved are really contained in it, whereas in the latter a new element is added by the predicate to those already contained in the subject, which was not previously understood in it, and therefore would not result from it by any analysis. For instance, the proposition that all bodies are extended is analytical; but the assertion that all bodies are heavy is synthetical. All the conclusions of experience are synthetical. Experience proves the possibility of the synthesis of the predicate 'heavy,' with the subject 'body;' for these two notions, although neither is contained in the other, are nevertheless parts of a whole, or of experience, which is itself a synthetical combination of its intuitions (*anschauungen*), although they only belong to each other contingently.

This contingent bond of union however is wholly wanting in synthetic judgments *à priori*. For instance, in the position, 'whatever happens has a cause,' the notion of a cause is not contained in the subject 'whatever happens,' and it indicates something very different from it. How then, and by what means, are we enabled to say of 'whatever happens' something absolutely different from it, and to recognise 'cause,' although not contained in it, as necessarily belonging to it? What is that unknown principle (=X) on which the understanding relies, when of the subject A it finds a foreign predicate B, and believes itself justified in asserting their necessary connexion? It cannot be experience, since in the above proposition the conception of a cause is attached to the subject, not merely generally, but universally and necessarily. Now all speculative *à priori* knowledge ultimately rests upon such synthetic or extending judgments; for though the analytical are highly important and requisite for science, still their importance is mainly derived from their being indispensable to a wide and legitimate synthesis, whereby alone a new acquisition in science can be made. The proper problem therefore of the pure reason is contained in the question—how are synthetic judgments *à priori* possible?

With a view to resolve this problem of the pure reason Kant begins with an exposition of the transcendental elements of knowledge (*transcendental elementarlehre*). By transcendental he understood original or primary, or whatever is determined *à priori* in reference not only to human cognition but also to man's collective activity, and which consequently is the basis of the empirical, or that which is determined *à posteriori*. In short, all pure knowledge makes up the transcendental philosophy, and on it rest the authority and possibility of cognition. The *elementarlehre* is divided into the transcendental æsthetic and the trancendental logic. In the former Kant investigates the *à priori* elements of the lowest cognitive faculty—sensation; in the latter, those of the understanding and of the reason. In the æsthetic he shows that the sensuous faculty receives the matter of its intuitions and sensations from without by means of certain affections or excitements of the sense, whereas the forms according to or by means of which this matter is shaped into representations or conceptions of determinate objects are given originally and by itself. These forms are the pure intuitions of space and time, because in them nothing else is intuitively viewed than the unity of that which is multiple either in succession or in co-existence. On this account he calls time and space forms of intuition, and designates the objects which we so intuitively view by the name of phenomena. Of the ground of these phenomena, or, as Kant termed it, the thing in and by

itself, it is left doubtful, and undetermined whether it is anything actual or not, notwithstanding that Kant ascribes to phenomena themselves a certain objectivity or reality, on the ground that from their constancy and regularity they cannot be a mere semblance or illusion of the senses. On this account his theory has been called a transcendental idealism, as being in nowise inconsistent with that system of empirical realism which by our conduct in life we practically maintain.

Transcendental logic is divided into analytic and dialectic, of which the former is the critic, or investigation of the understanding, as the faculty of notions; the latter, of the reason, as the faculty of ideas. In the analytic we are taught that it is only when objects have been conceived by the understanding agreeably to its laws, that they can become an object of knowledge. The operations of the understanding are confined to analysis and synthesis, where however every analysis presupposes a synthesis. A combination of the multiple into unity constitutes a notion (*begriff*), and the understanding is therefore the faculty of notions. The law of the forms of these notions, irrespective of their contents, is investigated by logic in general, whereas the investigation of these notions in reference to their contents is the proper office of transcendental logic. Notions are either pure or empirical: the former indicating merely the nature and the manner of their combination; the latter, the multiple matter presented by experience. Both are equally necessary to knowledge, for the pure notion is an empty thing apart from the representations, and the latter without the former are blind (*Kritik d. rein. Vern*, p. 55). As sensation only receives matter upon the affection of the senses, it is a mere receptivity, whereas the understanding, which subsumes the given multiple into unity, is a spontaneity. The consciousness of the individual in this multiplicity is effected by the imagination, which combines them into a whole; whereas the unity, by which the multiplicity, as sensuously perceived, is recognised as an object, is a work of the understanding. Now this unity constitutes the form of the notion, which therefore is the peculiar creation of the understanding. As these forms are different, a complete enumeration of them conformable to some stable principle is necessary in order to a discovery of the laws of knowledge by the understanding. Now all the primary modes of the operations of the understanding, whereby objective unity is imparted to the perceived matter, may be reduced to one of these four: quantity, quality, relation, and modality. These, with their subordinates, Kant denominates categories after Aristotle, as determining in and by themselves what in general and antecedently (*à priori*) may be predicated of objects.

The three categories of quantity are unity, multitude, and totality; those of quality, reality, negation, and limitation. Those of relation are double and are paired together, as substance and accident, cause and effect, action and re-action. Lastly, the subordinates of modality are possibility, existence, and necessity.

The process by which these 12 categories, or pure notions of the understanding, are combined with space and time, the pure intuitions of sensation, and thereby presented to knowledge in their possible application to the objects of sense, Kant calls schematism (σχηματισμός). For instance, the notion of substance is said to be schematised, when it is not conceived of absolutely as a self-subsisting thing, but as one which persists in time, and therefore as a constant and persisting substrate of certain variable qualities or determinations. Notions thus rendered sensible are called schematised, in opposition to the pure categories. In this process the imagination co-operates with the understanding, and its action is original and necessary, since its activity is inseparably bound up with the primary images of space and time. Out of this schematism of notions and the judgments which arise from their combination, the grand principles which regulate the operations of the understanding result. These judgments are either analytical or synthetical. The grand principle of the former in which identity affords the connexion between the subject and the predicate, is the principle of contradiction. The mere absence however of contradiction is not sufficient to legitimate the object matter of any proposition, since there may easily be a synthesis of notions which is not grounded in objects, notwithstanding that it is not inconsistent to conceive. In synthetic judgments, on the other hand, we go beyond the notion which forms the subject, and we ascribe to it a predicate, the connexion of which with the subject does not appear immediately from the judgment itself. The possibility of this synthesis implies a medium on which it may rest, and this is the unity of the synthesis in truth *à priori*. The following is the ultimate principle of synthetic judgments:—All objects are subject to the necessary conditions of the synthetic unity of the multiple objects of intuition in a possible experience. As this unity is established according to the table of categories, there must be as many pure synthetic principles as categories, and the different characters of their application must depend upon the different characters of the latter. These are either mathematical, and relate to the possibility of intuition, or dynamical, and relate to the existence of phenomena. Accordingly the principles of the understanding are, relatively to their use, either mathematical or dynamical. The former are unconditionally necessary, since the possibility of intuition depends upon them; the latter only conditionally necessary, for so far as concerns the existence of phenomena, which for a possible experience is contingent, they imply the condition of empirical thought, notwithstanding that in their application to it they invariably maintain their *à priori* necessity.

By these principles of the pure understanding the possibility of mathematics and of a pure science of nature may be fully and satisfactorily explained. The matter of mathematics is the multiple object of space and time, which are given as the forms of *à priori* intuition. This multiple matter is elaborated by the understanding according to the rules of logic, and as the phenomena must be in accordance with the conditions of space and time, or the forms under which they are intuitively viewed, *i.e.* the relations of space and time must be discoverable in phenomena themselves. The possibility of mathematics therefore rests simply on this, that objects cannot be conceived of except in space and time, from which however it follows at the same time that mathematics do not admit of application beyond the sphere of sensible phenomena. The pure science of nature likewise cannot have any other object than the system of *à priori* laws. It is only under the forms of sensation that individual objects can be intuitively viewed, and their mutual connexion cannot be thought of otherwise than under the forms of the understanding. If then the system of phenomena are to be an object of knowledge, they must correspond to the pure synthetical principles of the understanding, and it is only by these *à priori* laws that a science of nature is possible. But the principles of this pure science of nature do not admit of being applied beyond the domain of experience.

The important result of the transcendental logic is that the operations of the understanding are only legitimate in reference to experience, and that consequently the use of the understanding is empirical, and not transcendental. It would be the latter if it could apply itself to objects not as phenomena merely, but as things absolutely. But such a use of the understanding is obviously invalid, since the objective matter of a notion, or *begriff*, is given by intuition alone, and it is only by means of the empirical that the pure intuition itself comes to the object of which it is the form. These forms are simply representations of the object according as it conceived under them. To the *subsumtion* of an object under a category, a schema, 'time,' is indispensable, and, apart from all sensation, this schema itself does not subsist; and the subsumtion, or arrangement of an object under the categories, is impossible. There may undoubtedly be a logical use of the categories beyond the domain of experience, but this, notwithstanding that it has its ground in the nature of human reason, is either altogether idle, or else involved in contradictions (antinomie) which the transcendental dialectic investigates.

But besides phenomena there are other objects presented to the understanding, by a non-sensuous intuition of which consequently it can take cognisance. These Kant calls *noumena* (νοόμενα). The distinction between noumena and phenomena does not consist merely in a logical difference of the greater or less distinctness of their cognoscibility, but in a specific difference of the objects themselves. A noumenon is not the thing in and by itself, for the thing in and by itself becomes evanescent for knowledge when conceived of independently of all sensuous forms. Nevertheless as experience invariably refers back to something independent of and prior to sensation, the noumenon may be considered as an object which is presented to the under-

standing by an unsensuous intuition. The general possibility of such a species of intuition is undeniable, notwithstanding that its objects are impossible to be known by man, whose knowledge is dependent on sensation. In a positive sense Kant applies the term of *noumenon* to the notion of God, and generally to all supra-sensible objects, which may be conceived of, but nevertheless cannot be an object of perception.

The criticism of the transcendental dialectic gives this result—that the ideas of the reason, as pure speculative ideas, are nothing more than simple conceptions, for which no corresponding object can be scientifically shown to exist. Accordingly neither the existence of God, nor the immortality of the soul, nor the freedom of the will, can be demonstratively established. Nevertheless the reason is not merely a theoretical, but also a practical faculty, *i.e.* it gives the law of human conduct and action. Now these laws present themselves with such unconditional necessity (the *categorical imperative*), that no rational man endued with self-esteem can refuse obedience to them; and, on the other hand, without the freedom of the will these laws could not be obeyed; and without God and the soul's immortality there would be no final cause or motive for human conduct, which must be placed in a state of felicity, agreeable to morality, provided by and to be obtained through God, in another and a better life. Consequently every man who is conscious of his moral destination holds these practical ideas to be both true and objectively legitimate, notwithstanding that he is compelled or required to admit them merely by a subjective ground—the testimony of his own consciousness, and of the moral wants resulting from its dictates. This Kant calls the postulate of the practical reason. The acceptance of this postulate as true and legitimate does not constitute a scientific certainty, or knowledge properly, which indeed does not exist for the supra-sensible; it is merely a belief. This faith, or belief, however, is thus distinguished from every other, that it is a moral or practical faith, and consequently possesses for the believer all the certainty requisite for the guidance and conduct of life, and consequently it enjoys a subjective certainty and authority. This faith is the proper foundation of religion, which is nothing else than a conscientious observance of all duties as divine commands, since God, as the moral law-giver, cannot be worthily honoured otherwise than by obedience to the laws of morality.

Lastly, the critic of the faculty of the judgment (*urtheilskraft*) investigates its operations from an æsthetical or teleological point of view. The totality of objects which constitute nature are in harmony with man's faculty of knowledge. Every object may be considered æsthetically or teleologically; it possesses as it were two natures, one æsthetical and one teleological. The former is the point of view under which it appears to man; the latter consists in its formal or material concordance with the general harmony of things. Now the agreement which we perceive to subsist between a particular object and such an end does not belong to and is not in the object itself. It is, on the contrary, purely subjective; it belongs to the mind that discovers it, and is dependent upon the mental constitution. In the same manner the judgment is of two kinds. It may either refer to man's mode of conceiving and apprehending objects, and to the degree of pleasure with which the perceptions of them are accompanied; or it may consider the harmonious co-ordination of all things and their subordination to a general end, *i.e.* the objective harmony of nature. The beautiful, the agreeable, and the useful are the forms of our æsthetical judgments, and the perceptions of them are accompanied with pleasure. Nevertheless they affect us differently, and the sensation of pleasure which the beautiful occasions is of all the most complete. The beautiful is the most noble and most elevated of all the forms of æsthetical judgments. It exists in us antecedently to and independently of all experience. It is inherent in us, and forms a constituent element of our proper nature. Our judgments of objects are as necessarily respective of the beautiful as the practical reason is of the just and the good.

The knowledge of nature is only possible on these two conditions: that there are certain relations subsisting between the system of nature and the human mind; and that harmony reigns throughout the system of natural objects, and the necessary subordination of each separately to some general end. Considered in this light, organical being is the most excellent production of nature. The examination of any organical body displays an admirable subordination of the parts to the whole, and the whole itself is in exquisite harmony with each of its parts. But at the same time the whole itself is but a mean to other ends, a part in a greater totality. Consequently the most exalted form of the teleological judgment is that which considers the whole system of nature as one vast organical structure Thus considered, the synthetic activity of the judgment exercises itself in two ways, either æsthetically or teleologically. In the former case it refers all its decisions to the idea of the beautiful; in the latter, it subordinates all things to a final cause.

No complete edition of the works of Kant has yet appeared. The most important in a philosophical sense are the 'Kritik der reinen Vernunft,' 7 ausg., Leipzig, 1828; 'Kritik d. praktischen Vernunft,' 6 ausg., Leipz., 1827; and the 'Kritik d. Urtheilskraft,' 3 ausg., Berl., 1827. For a list of his other works see Tennemann's *Manual of the History of Philosophy* (English translation), p. 409, Oxford, 1832.

KANTEMIR, PRINCE ANTIOCHUS DMITRIJVITCH, descended from a family of Turkish extraction, was born at Constantinople, September 10th, 1708. He received his first education at Kharkov, whence he proceeded to the academy at Moscow, where he made such proficiency in his studies that when scarcely ten years old he composed and recited a discourse in Greek on St. Demetrius. In 1722 he accompanied his father, who was hospodar of Moldavia, in the campaign against Persia, after which (1725) he prosecuted his studies in the Academy of Sciences at St. Petersburg, directing his attention to that language whose literature he subsequently enriched. It was not long before his talents recommended him to the notice of the empress Anne; and in 1731 he was despatched to the British court in quality of resident, but in the following year was promoted to be ambassador extraordinary and plenipotentiary, in which capacity he was sent in 1738 to the court of France. The empress Elizabeth confirmed all the dignities that had been bestowed upon him by her predecessor. He died at Paris, March 1, 1774, of dropsy in the chest, and his body was conveyed to Moscow for interment in the Greek cloister.

Equally amiable and intelligent, his aim as a writer was to inform and correct, as is sufficiently attested by his Satires, which if now somewhat antiquated in regard to versification and style, are justly esteemed for their originality, truth, and force of colouring, and for the philosophical mind which they display. Both Zhukovsky and Batiuskkov have eulogized the merits of Kantemir as a writer and a man; the first in an analytical essay on his Satires, the other in a very interesting sketch entitled 'An Evening with Kantemir,' a long extract from which may be found in the second volume of the 'Foreign Review.' His other works were chiefly translations, viz. ten of the 'Epistles of Horace,' Fontenelle's 'Plurality of Worlds,' Epictetus, Cornelius Nepos, Montesquieu's 'Persian Letters,' &c.; but except the two first none of the others have been published.

KAOLIN, the Chinese name for porcelain clay. It occurs massive and disseminated in disintegrating granite rocks, and is generally supposed to be derived from the decomposition of the felspar which they contain. Its colour is either white, yellowish, or reddish-white. Fracture fine earthy; soft, dull, and opaque; adheres to the tongue; specific gravity 2·216; infusible.

Kaolin is found in China, France, Saxony, &c.; and in England a large tract of this substance occurs near St. Austle in Cornwall, on the south side of the granite range. It contains crystals of felspar, quartz, and mica. From this source the porcelain manufactory of Worcester is supplied.

Analysis by Berthier:—

	Limoges.	Schneiberg.
Silica	46·8	43·6

	99·6	95·4

Rose analyzed a Kaolin which was composed of 56 silica and 44 alumina.

KARABAGH. [GEORGIA.]

KARAMSIN, NIKOLAI MIKHAELOVITCH, one

of the most eminent writers that Russia has yet produced, and the one to whom its literature is mainly indebted for the popularity it has acquired, and the rapid progress it has made since the commencement of the present century, was born in the government of Simbirsk, December 1st, 1765. Having completed his education at Moscow, he served with a commission in the Guards, and in 1789-91 visited Germany, Switzerland, Italy, France, and England, which tour he has described in his 'Letters of a Travelling Russian,' of which there exists an English translation, or rather a copy of the German one. On his return to Moscow he devoted himself entirely to literature, one of his first undertakings being the 'Moscow Journal,' which was succeeded by 'Aglaia,' the 'Pantheon,' and the 'Væstnik Europæ,' or European Intelligencer (1802). Besides various narratives and other papers, both original and translated, these publications contained many articles of criticism by him, and were well calculated to promote a love of reading among all classes of his countrymen. These however were comparatively insignificant productions, chiefly remarkable for careful polish and correctness of style. The great work to which he entirely devoted himself from 1803 to the very time of his death, is his 'History of the Russian Empire,' which however he did not live to complete beyond the eleventh volume. This laborious task, which may in more senses than one be said to be the very first historical work in Russian literature, is a monument both of diligence and genius. The labour of collecting and arranging the vast mass of materials requisite for it must have been immense, yet never was historian more liberally repaid by the enthusiasm with which his work was instantly received. Its sale and popularity were unprecedented; it was to be seen everywhere, in the hut of the peasant and the palace of the noble; and no wonder, for in spite of all the imperfections that the utmost rigour of criticism has been able to allege against it, it is most captivating and interesting to all who are capable of perusing it in the original, whether foreigners or natives. It has been translated both into German and French, but with what degree of fidelity or ability we are unable to state. The first edition, comprising the first eight volumes (1816), produced him the sum of 100,000 rubles, also the title of counsellor of state, and the order of St. Anne, which were bestowed on him by the emperor Alexander.

After his death the twelfth volume, then nearly prepared in manuscript (bringing the history down to 1611), was edited by M. Bludov, minister of the interior. Since then a continuation of the work has been undertaken. Karamsin died in the Tauridan palace, where apartments had been assigned him, June 3rd, 1826. The emperor munificently bestowed on his widow and family a yearly pension of 50,000 rubles.

His merits and celebrity as an historian and a prose writer have so completely eclipsed his reputation as a poet, that he is scarcely ever considered in that character, notwithstanding that his poetical pieces are not without their value. In his private character he was amiable, noble, liberal, and disinterested; and an interesting sketch of his domestic habits has been given by Bulgarin in a piece entitled 'My First Acquaintance with Karamzin,' an English translation of which has appeared in the 'Old Monthly Magazine.'

KARPHOLITE, a mineral which occurs in minute crystals and in stellated silky fibres. Scratches fluor spar, and is scratched by felspar; colour wax or straw yellow. Lustre of the crystals vitreous; of the fibres silky. Specific gravity 2·93.

Before the blowpipe on charcoal fuses into a dark glass, which becomes darker in the interior flame. With borax it melts into a transparent glass, which in the exterior flame has a manganese colour, and in the interior becomes greenish.

Analysis by

	Stromeyer.	Steinman
Silica	36·154	37·53
Alumina	28·669	26·48
Oxide of manganese	19·160	17·09
Oxide of iron	2·290	5·64
Lime	0·271	..
Fluoric acid	1·470	..
Water	10·780	11·36
	98·794	98·10

KARPHOSIDERITE, hydrous phosphate of iron, occurs in reniform masses. Structure granular, compact; fracture uneven; hardness 4·0 to 4·5; specific gravity 2·5; colour pale and bright straw yellow, and streak the same; lustre resinous; feels greasy; opaque: when heated in a tube gives off water, and a vapour which reddens litmus paper.

Before the blowpipe, *per se*, it becomes black, and melts into a globule which obeys the magnet; with salt of phosphorus, it forms a black scoria. It is found at Labrador.

KATMANDU. [NEPAUL.]

KATTI. [HINDUSTAN, p. 221.]

KEATS, JOHN, was born in Moorfields, London, in the year 1796. He received a classical education at Enfield, under Mr. Clarke, and was afterwards apprenticed to a surgeon. Mr. Clarke introduced him to Mr. Leigh Hunt, who is said to have introduced him to public notice. In 1817 he published a volume containing his juvenile poems, and shortly afterwards his long poem 'Endymion,' which called forth a violent attack from the 'Quarterly Review.' Keats was of a remarkably sensitive disposition: his constitution was weak, and greatly impaired by the attentions which he bestowed on a dying brother, and his death has been attributed to the shock which he received from the article in the 'Quarterly.' Lord Byron seems to have believed this, and in his 'Don Juan' alludes to the circumstance, concluding with the reflection:—

> 'Tis very strange, the mind, that fiery particle,
> Should let itself be snuffed out by an article.'

To recover his health, Keats travelled to Rome, where he died on the 24th of February, 1821, having previously published a third volume of poems, containing 'Lamia,' 'Isabella,' 'The Eve of St. Agnes,' and 'Hyperion.'

The poetry of Keats is of an exceedingly rich and luxuriant character, and his writings so crowded with images, that it at last becomes almost fatiguing to apprehend them. It seems as if his imagination were of that volatile nature which must start off to every idea associated with his subject, and embody it as a part of the whole. Hence the reader must put himself in the place of the poet, and allow his own imagination to fly from thought to thought, or the work will seem but a compound of wild unconnected pictures. The article in the 'Quarterly' observed, that he introduced many images merely for the sake of rhyme, and this remark is not wholly unjust. He did not however, like many poets, merely write some common-place epithet or sentence for the sake of rhyme; but it seems as if his imagination was so fertile, that a chiming word brought with it a new image suitable to his purpose. Some have thought that time would have matured his judgment and have improved him, but this is doubtful; the wild transition from thought to thought is the essence of his poetry, and not a mere accident, and a cool inquiry into the aptness or connection of his images would rather have injured him as a poet than have been of advantage.

To elucidate the above remarks, a passage is selected by way of example:—

> 'Oh! magic sleep—oh! comfortable bird,
> That broodest o'er the troubled sea of the mind
> Till it is hush'd and smooth'd! Oh! unconfined
> Restraint! Imprison'd liberty! Great key
> To golden palaces, strange minstrelsy,
> Fountains grotesque, new trees, bespangled caves,
> Echoing grottoes, full of trembling waves
> And moonlight; aye, to all the mazy world
> Of silvery enchantment!'——

The poet begins by representing sleep under the figure of the bird brooding over the mind, and, still having the idea of comfort associated with that of sleep, does not hesitate to give the bird the dubious epithet 'comfortable.' Then suddenly dropping sleep as an active power (the *brooding* bird), he takes it as a state, and finds the paradoxical expressions 'unconfined restraint,' 'imprison'd liberty.' The word liberty gives rise to the question 'liberty for what?' The answer is, 'to roam in the world of dreams;' and the fertile imagination of Keats at once converts sleep into a key which is to open the gate leading to that world. The above is a fair specimen of the richness and wild luxuriance of Keats's poetry, and the tendency of his mind to dart in all directions for images.

The article in the 'Quarterly' dwelt too much on the

form of the poetry, and did not regard the beauty of many of the thoughts, nor the great power displayed of giving a being and a presence to the wildest imaginations. Hence most of the observations were just, but the poet was only regarded on his most unfavourable side.

Again Keats laid himself greatly open to ridicule; he evidently lived in a world created by his own imagination; the words that he used were to him symbols of beautiful thoughts, but he forgot that the sound of certain expressions is ridiculous in society, however appropriate the conception belonging to such words may be. Thus he says seriously, 'Dolphins *bob* their noses through the brine,' the justness of the image making him forget that an ordinary reader would necessarily smile at the word 'bob;' and this is one of numerous instances. Hence when the conventional rules of language are taken as the standard by which to judge him, he is always open to attack.

In the sublime Keats is not so happy as in the wildly beautiful. In the fragment 'Hyperion,' where we miss the exuberance, we also miss the brilliant fancies of the 'Endymion,' while at the same time the attempt at sublimity is rather an incumbrance.

In conclusion, it may perhaps be said, the works of Keats are adapted only to those who are really of a poetical temperament, and who have an imagination capable of following if not of creating. To the readers who look for poetry as a pleasant form of some clear and connected subject, who prefer authors that rather anticipate their imagination than call it into violent action, Keats's poems will be of small value.

KEEPER, LORD. [LORD KEEPER.]

KEIGHLEY. [YORKSHIRE.]

KELP, the ash remaining after the incineration of seaweed, which is burnt for the purpose of obtaining carbonate of soda from it. It contains but little of the alkaline salt, but a large quantity of common salt, some salts of potash, and probably iodide of sodium. It was formerly much used in glass and soap making, and from the residue, after separating the carbonate of soda, large quantities of iodine are now obtained. [SODIUM.]

While a heavy duty was imposed upon barilla imported from foreign countries, a considerable quantity of kelp was made on the coasts of Ireland and the western coasts and islands of Scotland, the inferior quality of the native production being more than compensated by its exemption from duty. The business of kelp-burning was long before carried on in Ireland, and about a century from the present time the manufacture was begun in Scotland, where, in consequence, the land in certain localities by the sea-shore became greatly advanced in value, very large annual revenues being derived from estates which had previously been wholly unproductive. The adoption of a more liberal line of commercial policy in this country, and the advancement of chemical science, have caused the manufacture of kelp to be given up, and the rocks and shores on which it was produced have again become valueless.

From the impurity of the alkali, and the large proportion of foreign matters combined with it, kelp could be used only in processes of a coarse description: its principal employments were in the manufacture of soap and common bottle-glass, for which purposes a better and cheaper alkali, made from common salt (chloride of sodium), is now used, and the only purposes for which sea-wrack is at present collected are the manuring of land, and, in hard seasons, the supply of winter food for cattle. Kelp having never been subject to the payment of duty, no record was ever taken of the quantity produced, which was at one time estimated to be more than 25,000 tons annually.

KELSO. [ROXBURGHSHIRE.]

KEMBLE, JOHN PHILIP, was born on the 1st of February, 1757, at Prescot, in Lancashire. His father, Mr. Roger Kemble, was manager of a provincial company performing in Staffordshire, Warwickshire, Gloucestershire, &c. His mother's maiden name was Ward. John Kemble was not intended by his father for the stage, although during his childhood he was occasionally called upon to represent parts suitable to his age, the first upon record being that of the little Duke of York in Havard's tragedy of 'Charles I.,' his sister Sarah (afterwards Mrs. Siddons) acting the Princess Elizabeth. This was on the 12th of February, 1767, Mr. Kemble being then just ten years old. He received the rudiments of education in a preparatory school at Worcester, from whence he was sent to the Roman Catholic seminary of Sedgeley Park, in Staffordshire, and afterwards to the English college at Douay, in France, where he made great progress. At the age of nineteen he returned to England, and following immediately the natural bent of his inclination towards the stage, made his appearance in the character of Theodosius in the tragedy of that name, at Wolverhampton, January 8th, 1776. Two years afterwards he was a regular member of the York Company. On Tuesday, 30th of September, 1783, Mr. Kemble made his first appearance in London at the Theatre Royal, Drury-lane, in the character of Hamlet. In 1790 he became manager of that theatre. In 1803 he purchased for 24,000*l.* a sixth share in Covent-garden Theatre from Mr. Lewis, and became manager of that establishment, having previously made a tour through France and Spain. In 1808 Covent-garden was destroyed by fire, and on the 31st of December, at the ceremony of laying the foundation-stone of the new theatre, Mr. John Kemble's bond for 10,000*l.* was munificently cancelled by his Grace the late Duke of Northumberland. On the opening of the new theatre in 1809, under Mr. Kemble's management, an advance in the prices of admission to the pit and boxes gave rise to the well-known O. P. riots, during which the great tragedian was personally and grossly insulted whenever he appeared upon the stage. A compromise was at length made between the manager and the public, and Mr. Kemble continued to direct the entertainments at Covent-garden in the best spirit of enterprise and liberality, reviving the plays of Shakspeare with great splendour and as much propriety as was at that time perhaps within his power. On the 23rd of June, 1817, he took his leave of the London audience, having previously bid farewell to that of Edinburgh (March 29th), and on the 27th of June a public dinner was given to him at the Freemasons' Tavern, when Lord Holland was in the chair. Mr. Kemble, who had long suffered severely from asthma, soon afterwards retired to the south of France for the benefit of his health, and, after a short visit to England on the death of his partner, the elder Mr. Harris, he finally took up his residence at Lausanne, in Switzerland, where he expired February 26th 1823, aged 66. Mr. Kemble's talents, both as an actor and a manager, were of a very high order: his fine taste and classical acquirements were perceptible in every effort, and in his personation of the loftier heroes of the drama he has never been equalled. His Brutus, Coriolanus, Cato, King John, Wolsey, and Macbeth, are still fresh in the remembrance of thousands, and, while the recollection of them remains, his successors to the tragic throne must, in those particular characters, suffer by comparison. His King Lear also, as a whole, may be mentioned amongst his almost unapproachable impersonations. His very feebleness in his latter years added to the terrible truth of the picture. In society Mr. Kemble was ever the accomplished gentleman as well as the convivial companion, and to the last enjoyed the respect and regard of the noblest and wisest in the land. The theatrical profession owes him a deep debt of gratitude for the respectability to which he raised it by his example. He furthered the good work which Garrick had begun, next to whom he must always rank amongst the worthies of the drama. Mr. Kemble's life has been written by his friend Mr. Boaden, in two vols. 8vo.

KEMPIS, THOMAS A, born about 1380, at Kempen, near Cologne, studied at Deventer, in a religious congregation or community called 'the brothers of common life,' and afterwards became a regular canon of the monastery of Mount St. Agnes, of which his brother John of Kempis, was prior. He there applied himself to transcribing the Bible, the Missale, several works of St. Bernard, and other religious books. He was an excellent copyist, and very fond of that kind of occupation. He was employed fifteen years in transcribing a Bible in 4 vols. fol., which he completed in 1439. He afterwards began a collection of pious and ascetic treatises, among which were the four books 'De Imitatione Christi,' which have been erroneously ascribed to him as his own composition, but which he merely transcribed from older manuscripts. The question of the authorship of the work 'De Imitatione Christi,' which is a book of real merit, displaying a deep knowledge of the human heart, and of the world, as well as of the inward spirit of Christianity, has been often debated. It is however most generally attributed to John Gerson, chancellor of the university of Paris, and a great theologian, who died in 1429. (Barbier, *Dissertation sur les Traductions Françaises de l'Imitation de J C.*, Paris, 1812.)

Thómas à Kempis composed some ascetic treatises, such as 'Dialogus Novitiorum de Contemptu Mundi,' &c., but they are very inferior to the book 'De Imitatione J. C.' He wrote also a Chronicle of his Monastery, and other compilations. He died in 1471, at ninety years of age.

KEMPTEN (the antient Campodúnum), a town of Bavaria, in the old duchy of Suabia, and the modern circle of the Upper Danube, on the bank of the Iller, in 47° 44′ 40″ N. lat. and 10° 18′ 45″ E. long. It is built in the old-fashioned style, and consists of two parts, that called the *Stifts-stadt*, or St. Hildegard, which is situated on a mountain, and is an open town, and the antient free imperial city, which is in the valley. It has a castle, two churches, a gymnasium, with a library and collection of works of art, an hospital, and an orphan asylum. There are manufactures of cotton and linen, and considerable trade in furs, wool, salt, linen, Italian and Dutch goods. The antient abbey was in the Stifts-stadt. The Prince Abbot was among the estates of the Empire, high marshal to the empress, was immediately under the pope, and possessed, with the district of Buchenberg, 326 square miles, 8 towns, 145 villages, with 43,000 inhabitants, and a revenue of 300,000 florins. The abbey and the town were assigned to Bavaria in 1802. The population of Kempten is about 7000.

KENDAL. [WESTMORLAND.]

KENEH. [EGYPT.]

KENILWORTH. [WARWICKSHIRE.]

KENNEBECK. [MAINE.]

KENNETT, WHITE, born 1660, died 1728, distinguished as a divine, antiquarian writer, and prelate of the Church of England; a man, as his biographer says, 'of incredible diligence and application, not only in his youth, but to the very last, the whole disposal of himself being to perpetual industry and service, his chiefest recreation being variety of employment.' His published works are, according to his biographer's catalogue, in number fifty-seven, including several single sermons and small tracts; but perhaps not a less striking proof of the indefatigable industry ascribed to him is to be seen in his manuscript collections, mostly in his own hand, now in the Lansdowne department of the British Museum Library of Manuscripts, where from No. 935 to 1042 are all his, and most of them containing matter not incorporated in any of his printed works.

His course in life was this: he was the son of a Kentish clergyman, educated at Westminster and Oxford, had the living of Amersden early bestowed upon him, with a prebend in the church of Peterborough, but returned to Oxford, where he became vice-principal of Edmund Hall, the college to which Hearne belonged; resigned Amersden; settled in London as minister of St. Botolph's, Aldgate; was a popular preacher; made archdeacon of Huntingdon, dean of Peterborough, and finally, in 1718, bishop of Peterborough.

His principal published works are:—1. 'Parochial Antiquities, attempted in the History of Ambrosden, Burcester, and other adjacent places in the counties of Oxford and Bucks,' 4to., 1695. This has been reprinted. In this work his very useful glossary is to be found. 2. 'The Case of Impropriations, &c., with an Appendix of Records and Memorials,' 1704. 3. 'A Register and Chronicle, Ecclesiastical and Civil,' in two volumes folio, 1728; relating to the events of a few years of the reign of King Charles II. He also published a corrected edition of 'The History of Gavelkind,' by William Somner, to which he prefixed a life of that eminent Saxonist. Most of his other works were either sermons or controversial tracts, many of the latter being in ecclesiastical controversy, in which he was reckoned what is called a Low Churchman; and having, previously to the Revolution, taken the opposite side, he was often severely handled by the other party. In particular, a sermon which he preached at the funeral of the first duke of Devonshire was severely animadverted upon, as if he gave too flattering a view of the character of the deceased for the sincerity of a Christian divine.

There is an octavo volume, published in 1730, entitled 'The Life of the Right Reverend Dr. White Kennett, late Lord Bishop of Peterborough,' from which the above particulars have been derived. It is anonymous; and as the fact is not generally known, it may not be improper to state that the author was William Newton, rector of Wingham in Kent.

KENNICOTT, BENJAMIN, was born of humble parents, at Totness in Devonshire, April 4th, 1718. Being appointed master of a charity-school in his native town, he continued in this situation till 1744, when several of his friends raised a sufficient sum of money to enable him to go to Oxford. He entered at Wadham College, and applied himself with the greatest diligence to the study of divinity and Hebrew. While he was an undergraduate he published a work 'On the Tree of Life in Paradise, and on the Oblations of Cain and Abel,' which was so well received by the public that the university allowed him to take his degree before the usual time, without the payment of the customary fees. He was elected a Fellow of Exeter College shortly afterwards, and took his degree of M.A. in 1750. He continued to reside at Oxford till the time of his death, which happened September 18th, 1783. He was a canon of Christ Church, and librarian of the Radcliffe Library, to which office he was appointed in 1767.

The most celebrated of Kennicott's works is his edition of the 'Hebrew Bible,' which was published at Oxford in 2 vols. fol., the first volume in 1776, and the second in 1780. In 1753, Dr. Kennicott published a work 'On the State of the Printed Hebrew Text of the Old Testament,' which was succeeded by another volume on the same subject in 1759. The first volume contained a comparison of 1 *Chron.* xi. with 2 *Sam.* v., xxiii., with observations on 70 Hebrew manuscripts, in which he maintained that numerous mistakes and interpolations had crept into the Sacred Text. In the second he gave an account of numerous other manuscripts of the Hebrew Bible, and proposed an extensive collation of Hebrew Manuscripts, with the view of publishing a correct edition of the Hebrew Bible. This undertaking met with much opposition from several persons, who were afraid that such a collation might overturn the received reading of various important passages, and introduce uncertainty into the whole system of Biblical interpretation The plan was however warmly patronized by the majority of the clergy, and nearly 10,000*l.* were subscribed to defray the expenses of the collation of the manuscripts and the publication of the work. Several learned men were employed both at home and abroad, and more than 600 Hebrew manuscripts, and 16 manuscripts of the Samaritan Pentateuch, were collated either wholly or in the more important passages. The business of collation continued from 1760 to 1769, during which period Dr. Kennicott published annually an account of the progress which was made. Though the number of various readings was found to be very great, yet they were neither so numerous nor by any means so important as those that are contained in Griesbach's edition of the New Testament. But this is easily accounted for from the revision of the Hebrew text by the Masorites in the seventh and eighth centuries, and from the scrupulous fidelity with which the Jews have transcribed the same text from that time.

'The text of Kennicott's edition was printed from that of Van der Hooght, with which the Hebrew manuscripts, by Kennicott's direction, were all collated. But as variations in the points were disregarded in the collation, the points were not added in the text. The various readings, as in the critical editions of the Greek Testament, were printed at the bottom of the page, with references to the corresponding readings of the text. In the Pentateuch the variations of the Samaritan text were printed in a column parallel to the Hebrew; and the variations observable in the Samaritan manuscripts, which differ from each other as well as the Hebrew, are likewise noted, with references to the Samaritan *printed* text. To this collation of manuscripts was added a collation of the most distinguished editions of the Hebrew Bible, in the same manner as Wetstein has noticed the variations observable in the principal editions of the Greek Testament. Nor did Kennicott confine his collation to manuscripts and editions. He further considered that as the quotations from the Greek Testament in the works of ecclesiastical writers afford another source of various readings, so the quotations from the Hebrew Bible in the works of Jewish writers are likewise subjects of critical inquiry. For this purpose he had recourse to the most distinguished among the Rabbinical writings, but particularly to the Talmud, the text of which is as antient as the third century.' (Marsh's *Divinity Lectures*, part ii.)

Kennicott annexed to the second volume a 'Dissertatio Generalis,' in which he gives an account of the manuscripts and other authorities collated for his work, and also a history of the Hebrew text from the time of the Babylonian

captivity. This dissertation was reprinted at Brunswick in 1783, under the superintendence of Professor Bruns, who had collated a great number of manuscripts for the original work.

An important Supplement to Kennicott's Hebrew Bible was published by De Rossi, under the title of 'Variæ Lectiones Veteris Testamenti,' Parma 1784-88, 4 vols. 4to.; to which an appendix was added in 1798.

The works of Kennicott and De Rossi are too bulky and expensive for general use. An edition of the Hebrew Bible, containing the most important of the various readings in Kennicott's and De Rossi's volumes, was published by Doederlein and Meissner, Leip. 1793; but the text is incorrectly printed, and the paper is exceedingly bad. A far more correct and elegant edition of the Hebrew Bible, which also contains the most important of Kennicott's and De Rossi's various readings, was published by Jahn, Vienna, 1806, 4 vols., 8vo. which may be recommended as the best critical edition of the Hebrew Bible.

Two scholarships were founded at Oxford by the widow of Dr. Kennicott for the promotion of the study of the Hebrew language.

KENT, a maritime county in the south-eastern corner of England. It is bounded on the north by the æstuary of the river Thames, by which it is separated from the counties of Middlesex and Essex; on the east by the German Ocean and by the Straits of Dover; on the south by the county of Sussex, from which it is separated in one part by the River Rother, in another part by the Teyse, or Teise, a feeder of the Medway; and in the south-western corner of the county by Kent Water and other branches of the Medway: on the west side the county is bounded by Surrey. A detached portion of the parish of Woolwich in Kent lies on the north side of the Thames.

The form of the county is irregular. Its principal dimensions are as follows: length of the northern boundary, from the neighbourhood of London to the North Foreland, 64 miles in a straight line; of the southern boundary, from the junction of the three counties, Kent, Surrey, and Sussex, to Denge Ness, or Dungeness, 43 miles; of the eastern boundary, from the North Foreland to Denge Ness, 38 miles; and of the western boundary, from the neighbourhood of London to the junction of the above counties, 24 miles: the length of a diagonal drawn from London to Denge Ness is 59 miles; and of one from the North Foreland to the junction of the above counties, 62 miles. The area is estimated at 1557 square statute miles; the population in 1831 was 479,155, giving 308 inhabitants to a square mile. In size it is the ninth of the English counties; in population the sixth; and in density of population the seventh. Maidstone, the county town, is on the Medway, 31 miles from London in a direct line south-east, or 34½ miles by the road by Eltham, Farningham, and Wrotham.

Coast-line, Islands, &c.—The northern part of the county, along the æstuary of the Thames, is skirted by a line of marshes extending inland from the Thames a distance varying from a few yards to a mile and a half or two miles. At the junction of the æstuaries of the Thames and the Medway these marshes are very extensive, and occupy a large portion of the tongue of land between these rivers, the extremity of which, being nearly or quite insulated by Yantlet Creek, forms what is termed the Isle of Grain.

Eastward of the Isle of Grain, the Swale, an arm of the æstuary of the Medway, cuts off from the main land the Isle of Sheppey, of which the isles of Elmley and Harty are subordinate portions, nearly severed from the rest by ditches or creeks. The northern side of the Isle of Sheppey is upland; the face toward the Thames is abrupt but not very lofty, the cliffs rising about ninety feet above the river. The southern part of the island is a low flat. The length of the island from east to west is about 10 miles; its greatest breadth from north to south about 5 miles. It probably once extended farther on the north side, but the cliffs have been gradually washed away. Its area is nearly 33 square miles, divided between seven parishes; it comprehends the antient but decayed borough of Queenborough, and the royal dockyard and town of Sheerness at its north-western point. The population of the island in 1831 was 9934. The surface is laid down for the most part in grass: but the upland part on the northern side produces good corn. The air is loaded with vapours in the low marshy grounds, and the water is brackish; the population is thin, except in and about Sheerness. The Isle of Sheppey constitutes a separate liberty (with the exception of Harty Island, which is in Faversham hundred), and had formerly a 'Court of Hustings for the trial of all causes or pleadings relating to the island. The marshes terminate east of the Swale, and the coast again rises to some height in clayey cliffs, which, with a slight interruption at Herne Bay, extend to Reculver and the flats which form the western limit of the Isle of Thanet. In the Isle of Thanet, which occupies the north-eastern corner of the county, the cliffs again commence and continue along the whole line of coast to Pegwell Bay, which is the boundary of the Isle to the south-east. The North Foreland is on the coast of the Isle of Thanet, due east of Margate.

The Isle of Thanet contains about 40 square miles with a population in 1831 of 26,090, and includes the well-known watering places, Margate, Ramsgate, and Broadstairs. It is now separated from the mainland only by the narrow channels of the Stour, one of which runs through the marshes to the æstuary of the Thames at Reculver, and the other enters the German Ocean in Pegwell Bay. The coast from the Isle of Sheppey to the North Foreland is skirted by sands which extend from a quarter of a mile to a mile from high-water mark; and for some miles farther out by 'the flats,' which, except in Margate Roads, rarely afford, when the tide is out, more than two fathoms water. Margate Roads are sheltered to seaward by Margate Sands, which are dry at low water.

The chalk cliffs of the Isle of Thanet are succeeded by the low coast of Pegwell Bay, which continues to Walmer Castle near Deal. Here the chalk cliffs recommence and continue round the South Foreland (a headland bearing 14 miles nearly due south from the North Foreland), to Sandgate between Folkestone and Hythe. Between Dover and Folkestone a portion of the chalk cliffs has fallen forward towards the sea, so as to present an under cliff similar to that at the back of the Isle of Wight. From the neighbourhood of Folkestone the coast begins to get lower until it forms the extensive tract of Romney Marsh, the coast line of which extends south-west to Denge Ness, a point 19 miles in a straight line south-west of the South Foreland, and from thence westward 6 or 7 miles to the border of the county of Sussex. Romney Marsh is in one part protected against the sea by an embankment called Dymchurch Wall. There are lighthouses at the North and South Forelands, and on Denge Ness, and beacons in various other places. Opposite to the coast which extends from the Isle of Thanet to the South Foreland lies the Goodwin Sand, the channel between which and the Kentish coast is the well-known roadstead of the Downs. The popular tradition is that the Goodwin Sand was once an island, forming the estate of Goodwin earl of Kent. This island, which some suppose to have been called Lomea, is said to have been destroyed by the sea, A.D. 1097. Others, with more probability, consider it to have been a shallow previously covered with a depth of water sufficient to admit the passage of vessels over it, but made bare about the above-mentioned period by the accumulation of sand. There has been an impression that the sand was possessed of a peculiarly 'voracious and ingurgitating property; so that should a ship of the largest size strike on it, in a few days it would be so wholly swallowed up by these quicksands, that no part of it would be left to be seen.' More accurate observers have however found that the sand is of the same quality with the sands on the opposite shore. The Goodwin Sand is of irregular form, about 10 or 11 miles long from north to south; its greatest breadth is three or four. It is divided into two parts by a narrow channel called 'the Swatch,' navigable by small boats.

The Downs, which are about 8 miles in length and 6 in width, are a safe anchorage, and are the general rendezvous of shipping leaving the Thames for the Channel, or returning homeward. They are sheltered on the west and north-west, and partially on the north sides, by the Kentish coast or by the sands connected with it: on the east side the Goodwin Sand forms a sort of breakwater. To the north of the Downs are 'The Small Downs,' a smaller roadstead immediately contiguous to the Downs properly so called.

Surface and Geology.—Kent is on the whole a hilly county. The chalk range of the North Downs enters the county on the west side from Surrey, not far from Westerham, and runs to the east-north-east to the valley of the Medway between Maidstone and Rochester. The southern slope of this chalk range is steeper than the northern, and

forms a line of hills, from the summit of which there is an extensive prospect. The North Downs are interrupted between the border of the county and the Medway by the valley of the Darent. On the eastern side of the Medway, which completely interrupts the chalk range, the Downs rise again, and run to the east-south-east to the coast near Folkestone, still presenting their steepest slope to the south. This part of the range also is divided into two parts by the valley of the Stour. On the north side the Downs gradually subside towards the æstuary of the Thames. The coast line from Walmer to Folkestone shows a transverse section of this range.

The breadth of the chalk formation, which thus extends through the county from west to east, varies; west of the Stour it is from three miles to six; east of the Stour it occupies the whole extent of the county north of a line drawn from Folkestone to Wye, except where it is interrupted by the marshy valley which surrounds the Isle of Thanet. The height of the chalk hills is considerable. Hollingbourne station, about midway between the valleys of the Medway and the Stour, is 616 feet above the level of the sea; Paddlesworth hill, about three miles north-west of Folkestone, is 642 feet; Folkestone hill, on the coast near Folkestone, is 575 feet; and Dover Castle hill is 469 feet. The cliffs near Dover are about 400 feet high. The cliffs of the Isle of Thanet are also of chalk; those about the North Foreland are from 100 to 200 feet high.

The district between the chalk range and the æstuary of the Thames is, for the most part, occupied by the plastic clay which immediately overlies the chalk. The tongue of land between the Medway and the Thames, including the Isle of Grain and the Isle of Sheppey, is formed of the London clay, which overlies the plastic clay. This formation also occupies a considerable district north and north-west of Canterbury, extending to the shore between Whitstable and Reculver, where (as well as in the Isle of Sheppey) it forms cliffs: those between Whitstable and Reculver are in some places 70 feet high. The London clay also covers a small tract near Pegwell Bay. The hills of Sheppey, which are of London clay, rise to the height of 200 feet. Shooters Hill, near Woolwich, which is an insulated mass of London clay, is about 446 feet high.

In the valleys of the Darent and its feeder the Cray the strata above the chalk have been washed away, and the chalk is covered only by the vegetable soil. Another strip of chalk, denuded of the superior strata, runs along the bank of the Thames from the valley of the Darent to below Gravesend.

South of the North Downs the chalk marl and green sand crop out, and cover a belt of land skirting the chalk throughout the whole extent of the county from west to east. The breadth of this belt varies from two miles to six or seven. Its southern slope, which is the steepest, forms what is designated 'the ragstone range' of hills, the higher points of which are from 600 to 800 feet high, and overlook the valley watered by the Eden, the Medway (from Penshurst to Yalding), and the Beult. The thickness of the chalk marl averages 300 to 400 feet; of that of the green sand we have no account.

The valley just referred to is occupied by the Weald clay, and forms another belt extending throughout the county from the border of Surrey to the edge of Romney Marsh, having an average breadth of five miles. The thickness of this formation may be estimated at about 300 feet.

The remaining portion of the county, which forms a narrow belt or strip of land along the Sussex border, is occupied by the iron-sand, which forms the nucleus of the great Weald district of the south-eastern part of England. This formation constitutes a range of hills, amid which the upper waters of the Medway and its tributary the Teyse have their sources; and extends far into Sussex. It rises in some parts of the Weald clay district through the overlying strata of that formation.

The county thus appears, when viewed with reference to its geology, to consist of five parallel belts, extending nearly in the direction of its length, and occupied by different formations, which succeed each other in regular order from north to south:—1, The London and plastic clays; 2, the chalk; 3, the chalk marl and green sand; 4, the Weald clay; 5, the iron-sand. The southern border of the chalk and green-sand formations, and the iron-sand district, form three parallel ranges of hills separated from each other by the Homesdale and Weald clay valleys, the former lying at the foot of the chalk hills, and the latter of the ragstone or green-sand hills.

What is termed the Weald (Saxon peald, a forest, or perhaps generally, a wild uncultivated tract) was antiently an immense forest, inhabited only by deer and hogs. It has however been gradually cleared and brought into cultivation. The iron-sand of this district was formerly much in request for the furnace and the forge; and the iron-works were numerous and important. But the introduction of coal in the manufacture of iron has caused this branch of industry to be transferred to other parts of the island where fuel is more abundant.

Beds of limestone occur in the green-sand formation, and are quarried near Maidstone for common purposes of building, for road-making, and for burning into lime, which is used for stucco, or exported to the West Indies for refining sugar.

Hydrography and Communications.—The northern boundary of the county is formed by the Thames, to the basin of which nearly the whole county belongs. This river affords to that side of the county a ready means of communication with the metropolis and with other parts. The royal dockyards of Deptford and Woolwich are upon it.

The other principal rivers are the Ravensborne, the Darent, and the Medway, which flow into the æstuary of the Thames; and the Stour, and the Rother, which flow into the sea.

The Ravensborne rises on Keston Common, near the border of Surrey, and flows northward past the town of Bromley and the village of Lewisham, and between the towns of Greenwich and Deptford, into the Thames. It turns several mills, and supplies Greenwich and Deptford with water by means of waterworks. It is navigable for nearly a mile up to Deptford bridge for lighters and other small craft. The whole length of the Ravensborne is about ten miles.

The Darent rises in Squirries park, near Westerham, just under the North Downs, and close to the border of Surrey. Its course is first east-north-east, parallel to the course of the North Downs, to Riverhead near Sevenoaks, where it turns north and passes through a depression in the Downs by Otford, Shoreham, Farningham, and other villages, to the town of Dartford, below which it is called Dartford Creek, and becoming navigable, flows through the marshes into the Thames. Its whole course is about twenty miles, for three of which it is navigable. Just before joining the Thames it receives the Cray, which rises near Orpington, and has a course of about nine miles. The Cray is said to produce the best trout of any stream in the neighbourhood.

The Medway rises in Sussex, near the northern border, between East Grinsted and Crawley, and flows eastward through that county into Kent, which it enters near Ashurst about five miles west of Tunbridge Wells. In this upper part of its course the Medway is swelled by many brooks, which drain the higher districts of the Weald of Sussex. At Penshurst, in Kent, the Medway is joined by the Eden, one of its main branches, which rises about Godstone, in Surrey, and receives the drainage of the valley that separates the green-sand hills from the central iron-sand high lands of the Weald. The Eden is about sixteen miles long. The length of the Medway before it receives the Eden may be estimated at eighteen miles. From Penshurst, where the navigation of the river commences, it flows east-north-east five miles to Tunbridge, forming in its way two or three islands. From Tunbridge the Medway flows eight miles east by north to Yalding, in the Weald, near which it is joined by the Toyse or Teise and the Beult. The Teise rises in the northern part of Sussex, and flows by Lamberhurst and between Horsmonden and Goudhurst into the Medway. Its length is about seventeen miles. It sends off an arm which joins the Beult. This river rises in the Weald of Kent, not far from the foot of the iron-sand hills, near Shadoxhurst, and flows north-by-west twenty miles to Yalding. The course of the Medway and of its principal feeder the Beult to their junction is in the direction of the valley of the Weald clay, of which they receive the drainage, the Beult of the eastern, and the Medway of the western part. From Yalding the course of the Medway, though very winding, is for the most part northward; it passes through an opening in the green-sand hills, across the prolongation of the valley of Holmsdale by Maidstone and Aylesford, through a great opening in the North Downs, and by Rochester and Chatham,

into the æstuary of the Thames at Sheerness. Its length below Yalding is more than thirty miles, and its total length above sixty, for more than forty of which it is navigable. The tide flows up to Maidstone bridge, just above which it is now stopped by a lock; it previously flowed a mile or two higher up. Ships and large vessels cannot ascend above Rochester bridge. Below Rochester the æstuary gradually expands to a considerable width, and forms an important harbour for the British navy. Numerous arms of the river or creeks penetrate the marshes, which spread inland to a considerable extent from the banks of the river. The royal dockyard of Chatham is on the Medway, and that of Sheerness at the junction of the Medway with the Thames. The Medway is plentifully stored with fish: above Maidstone is an abundance of the usual fresh-water fish; and below Rochester are soles, flounders, and other flat fish, and smelts of excellent quality and large size. In the creeks in the lower part of the river are considerable oyster-beds.

The British name of this river is said to have been Vaga, but if a judgment may be formed from the name given by Nennius to the town of Maidstone, 'Caer Meguaid' or 'Caer Megwad,' the first syllable of the modern name was also part of the British name, and not (as supposed by some) a Saxon addition. The Romanized name of a town mentioned in the Peutinger Table, and by Richard of Cirencester, supposed to be on this river, was Ad Madum or Madis, which corroborates the notion that 'Mag' or 'Mad' formed part of the British name.

The Stour has two main branches, distinguished as the Greater and the Lesser Stour. The Greater Stour is formed by two streams, which flow along the valley between the North Downs and the green-sand hills in opposite directions, one coming from the north-west near Lenham, the other from the south-east, not far from Hythe on the coast; they unite near Ashford, and, turning to the north-east, pass through a depression in the North Downs, and flow by Wye and Canterbury to the neighbourhood of Sarre in the Isle of Thanet. Here the Stour parts into two branches, one of which falls into the æstuary of the Thames, near Reculver; the other falls into Pegwell Bay, below Sandwich. These two arms cut off Thanet from the rest of the county, and constitute it an island.

The Lesser Stour rises near Lyminge, about three miles north of Hythe, and, flowing north by east to Barham, above which it sometimes becomes dry, turns north by west, and skirting Barham Downs, flows to Bridge near Canterbury. Here it makes another bend, and runs north-east into that arm of the Greater Stour which falls into Pegwell Bay. The two arms of the Stour, which insulate Thanet, were once a channel three or four miles over, which received several streams beside the Greater and Lesser Stour. This channel was called the Wantsume. In Bede's time the breadth was diminished to three furlongs, and was usually passable at two places only, Sarre and Stonar, near Sandwich, where ferry boats were kept. The channel continued to be navigable for ships of tolerable burden in the reign of King Henry VIII.; but subsequently the waters of the northern branch having been distributed by means of floodgates over the land, this arm from the Stour to Reculver became too small for navigation, and was for a period quite dry in the neighbourhood of Sarre, so that Thanet became a peninsula rather than an island. A cut from the Stour restored the continuity of the watercourse, but this north channel has never since been used for navigation. The Greater Stour enters Pegwell Bay after making a great bend, at the elbow of which Sandwich is situated. It is navigable up to Fordwich, near Canterbury. The whole length of the river from Lenham to Pegwell Bay may be estimated at forty-five miles. Both the Greater and the Lesser Stour contain excellent trout; salmon trout, generally of about nine pounds weight, are taken in the Greater Stour, and a peculiar species called the Fordwich trout, which are rather larger.

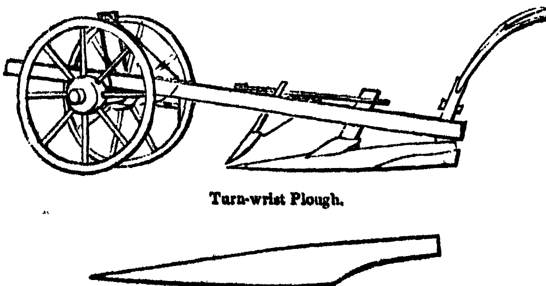
The river Rother rises in Sussex, to which county it more properly belongs. [SUSSEX.] It first touches the border of Kent at the junction of a small stream, which rises near Hawkhurst, and separates the two counties. From this junction the Rother flows by Newenden and Wittersham, below which it quits the border and re-enters Sussex. Several small streams from the Weald of Kent flow into it, and the arms of these, with the Rother itself, enclose the river island of Oxney (six miles long from east to west, and three miles broad), the centre of which is occupied by the hills about Wittersham, Stone, and Ebony Chapel, while the rest of the island (of which the greater part is in Kent) forms the continuation of Romney Marsh. The Rother is navigable in all that part which touches this county. This river, which was antiently called the Limene, once entered the sea at New Romney, but in the reign of Edward I., during a great inundation of the sea, it forsook its antient channel and formed for itself a new one into the sea at Rye.

The principal canal in the county of Kent is the Royal Military Canal, which was formed, rather for the purposes of defence than of commerce, during the alarm of invasion in the late war against Napoleon. It has however since been converted to commercial use. It runs along the edge of Romney Marsh from its commencement in the sea near Hythe to its junction with the Rother in the south-eastern corner of Oxney Isle. The line of this canal is very little above the level of the sea.

An act was obtained in 1812 for a canal to be cut from the Medway, just above the junction of the Teyse, to Ashford. It was to take a circuitous course through the Weald, and to have a branch by Tenterden to the Royal Military Canal. Nothing has ever been done under this act.

A canal, about nine miles long, extending from Gravesend to Frindsbury, opposite Chatham, unites the Thames and the Medway, and saves a circuitous navigation of forty-seven miles round the extremity of the Isle of Grain. It passes, by a tunnel about two miles long, through the chalk hills. There is a basin at each end of the canal.

Three principal roads traverse the county. The Dover road enters the county at New Cross, 3½ miles from London, and runs east-south-east in a very direct line through Deptford, Greenwich, Dartford (15 miles from London), Gravesend (22 miles), Rochester and Chatham (30 miles), Sittingbourne (40 miles) and Canterbury (55 miles) to Dover (71 miles). The principal communication between London and the Continent is by this road. The Hythe road branches off from the Dover road at New Cross, and runs south-east through Eltham, Farningham, and Wrotham, to Maidstone (34½ miles); and from thence by Lenham (44 miles), Charing, and Ashford (53 miles), to Hythe (65 miles). The Hastings road branches off from the Hythe and Maidstone road more than a mile beyond New Cross, and diverging more towards the south, passes through Bromley, Seven Oaks (24 miles), and Tonbridge (30 miles); at Lamberhurst (40 miles); it crosses a projecting angle of Sussex, and finally quits Kent for Sussex near Flimwell (45 miles). The road travelled by the Hastings mail diverges from this road at Tonbridge, and passes through Tonbridge Wells (36 miles from London). The road to Rye branches off from the principal Hastings road just before it quits Kent, and passes through Hawkhurst and Newenden (53 miles), where it crosses the Rother into Sussex. The roads to Margate and Ramsgate, and to Sandwich and Deal, branch off from the Dover road at Canterbury, and a branch from the Hastings road near Lamberhurst leads to Cranbrook and Tenterden, in the Weald, and to New Romney near the sea. A railroad from London to Dover is in progress. It is to branch off from the Brighton railroad about 20 miles from London, and to pass by Tunbridge, and from thence in a tolerably direct line by Ashford to Folkestone. From Folkestone it will pass by a road along the face of the cliffs and by a tunnel through Shakspeare's Cliff to the town of Dover.



Agriculture.—The climate of Kent is in general mild and genial. The proximity to the continent of Europe exposes it to occasional north-east winds, which chill the air, but they carry off the superfluous moisture of the soil; and some of the most fertile spots are in the Isle of Thanet, which lies at its north-eastern extremity, and in the adjacent parts. The soil of this county may be divided into the gravel, chalk, and clay, which produce, where they mix in due proportions, an extremely fertile loam. The alluvial soils along the Thames and Medway, and in Romney Marsh, produce some of the richest marsh pastures in the kingdom.

A ridge of hills composed of ragstone traverses the county from west to east, along which there are some very fertile clays, which, with moderate attention to the cultivation, are highly productive. The chalk, which lies chiefly to the north of these, rises into hills between Canterbury and Dover, where there are some extensive sheep-downs,

but from Canterbury towards London it is mostly covered by a stiff clay, and only breaks out here and there on the banks of the Thames. To the south of the ragstone hills are the Wealds, which contain some very fertile clays and woods, in which oaks grow to a great size. The soil in the Isle of Thanet is not naturally so fertile as the appearance of the crops might lead one to suppose. It consists mostly of a thin light soil; but it has been so long improved by careful cultivation and abundant manuring, chiefly with sea-weed, that it may now be considered one of the most fertile spots in Great Britain. The subsoil is everywhere a hard chalk, over which there is in some places a thin layer of earth mixed with flinty pebbles, not exceeding six or eight inches in depth: in some of the hollows the soil is deeper and more loamy, and so dry as to allow of its being ploughed quite flat without any ridges or water-furrows. There is not an acre of waste land in all the Isle of Thanet.

Throughout the whole county the clay may be said to predominate, and the mode of cultivation generally adopted is that which suits the strongest soils. The Kentish farmers and yeomen, though generally rich and independent, are not very ready to introduce improvements in the system by which their forefathers were enriched; and although a great quantity of corn is annually raised in the county, and contributes a great portion of the supply of the London market, it cannot be denied that this produce might be greatly increased, and raised at a less expense than it is now, by adopting improvements in the tillage of the land and the implements in use. An old Kentish farmer may perhaps smile at this assertion, and, looking at his fine fields of wheat and beans, defy any one to cultivate the land better. This is the very reason why improvements which have been introduced in less productive districts have made little or no progress in this county. In the year 1793, Mr. John Boys, who drew up the general view of the county of Kent, being himself a Kentish farmer, mentioned the heavy turn-wrist plough, used almost universally throughout Kent, as 'drawn by four horses on the lightest soils, and with six on all the stiffest;' and at this day, nearly half a century later, the old heavy turn-wrist plough is still used with four horses in soils where a good plough of an improved form would readily do the same work with two.

The Kentish turn-wrist plough consists of a beam ten feet long, five inches deep, and four broad, behind which is a foot five inches by three and a half, and three and a half feet long, on the top of which the handles are fixed. Through the beam, at two feet five inches from the foot, is a sheath of oak seven inches wide and one and a half thick, which is morticed into the chep in an oblique direction, so that the point of the share is twenty-two inches distant from the beam. The chep, to which the share is fixed, is five feet long, four inches wide, and five inches deep. The share is of hammered iron, weighs about 32 lb., is twenty inches long, and from four and a half to seven inches wide at the point. The upper end of the beam rests on a carriage with two wheels three feet two inches high: on the axletree is a gallows, on which is a sliding bolster to let it up and down. Through the centre of the axle is a clasp-iron, to which is fixed a strong chain called a tow. This comes over the beam, and, by lengthening it, the beam is let out a greater length from the axle, and thus the

Turn-wrist Plough.

Share of the turn-wrist Plough. The point is flat, like a chisel, for stiff clays, and with a blunt point for stony soils.

plough goes to a greater depth in the ground; by shortening it the reverse takes place.

We do not mean to disparage this plough for heavy soils, nor doubt the necessity of its being drawn by four horses in some very stiff clays; but it might be greatly improved, and the draught diminished, so as to save at least one horse in four. In clay soils, which are retentive of water, it is always advantageous to lay the land in stitches with deep water-furrows between them; and for this purpose the Suffolk or the Scotch ploughs with a fixed turn-furrow are much better adapted than the turn-wrist.

On the soils in the Isle of Thanet, where wheat and beans are raised alternately without fallow or intermission, the practice is good, and, if effected at a moderate expense, is not to be found fault with. The ground is well stirred and amply manured for the beans, which are drilled in rows with wide intervals, and repeatedly horse-hoed till the crop is too far advanced to admit of it. The returns cannot fail to be good. The bean stubble is cleared of the stems and roots of the beans by a plough with a very broad share, which effects a perfect hoeing and leaves the surface quite clean. A deep ploughing is then given for the wheat. We cannot suggest any improvement in this practice, unless it be in the economy of the labour. But such soils are very scarce, and much of the Kentish clays and loams must be cultivated with a greater variety of crops. There is room here for improvement, both in the rotations and in the manner in which each crop is raised; and the Kentish farmer might find it profitable to adopt some of the methods which experience has fully proved to be advantageous in soils and situations not so well adapted to them as many parts of Kent are. A journey through the northern counties of England and the south of Scotland would give the young Kentish farmer some useful hints, and would remove some prejudices which impede his progress in agriculture.

Besides the usual crops which are raised on good clays, Kent produces several which are peculiar to it, such as canary and radish seed, which grow chiefly in the Isle of Thanet, where there are few hedgerows to harbour birds, which are very destructive to these crops. The canary seed is cut in September, and is left for some time in the field until it is fit to be thrashed; for the seed adheres so strongly to the husk that it requires the influence of rain and exposure to the weather for some time to destroy the texture of the envelopment before it can be separated; and it suffers very little from this exposure. The produce is from three to five quarters per acre, and is chiefly used to feed birds kept in cages, and for this purpose is largely exported. The offal is very good food for horses. Radish seed is also cultivated in the richer soils for the London seedsmen. It is sown in drills and carefully hoed, so as to leave the plants eighteen inches asunder. The pods, when ripe, require to be left long in the field before the seed can be thrashed out. The produce is from eight to twenty-four bushels per acre. The demand for this seed is very great: every garden, however small, has a bed of radishes, and few gardeners think it worth while to save the seed.

Other seeds are likewise raised for the London seedsmen, such as spinach, cresses, and white mustard. Kidney beans are cultivated to a considerable amount in the neighbourhood of Sandwich, and produce from ten to twenty bushels per acre.

Woad and madder were formerly more commonly cultivated in Kent than they are now; the foreign, being raised at a less expense, have driven the Kentish out of the market. With a greater attention to the management of these valuable crops, they might probably still be raised advantageously; but everything which is done in Kent is done in a more expensive manner than in many other countries; a great proof of the easy circumstances of the farmers and landowners there.

There is comparatively a very small proportion of grass land in Kent, if we except the sheep downs on the chalk hills and the marshes. The marshes produce most of the hay consumed in winter. Romney Marsh, which is well known for the richness of its grass, contains about 44,000 acres; on the borders of the Stour are 27,000; and along the Medway, Thames, and Swale, about 11,500 more. A great many sheep are reared and fattened in these marshes. The cattle fed there are only a secondary consideration, sheep being found more profitable. The quantity of sheep which the land will keep varies from two to five per acre; sometimes the grass grows faster than the flock can consume, and becomes too rank, a circumstance which is owing to want of attention in stocking, and is detrimental. Lean cattle are then taken in to eat it close;

but a careful farmer never allows his marshes to be either over or under stocked, and keeps the grass close fed and yet abundant. The hay made in the marshes is often stacked in the marsh itself, near some shed, where the stock may be supplied in winter.

There are very few dairies of any consequence in Kent, nor is any cheese made, except for domestic consumption.

Hops are grown to a very great extent in this county; and, with the exception of those which are raised at Farnham in Surrey, are the most esteemed of any in England. [HOPS.]

In that part of Kent which is nearest to London there are many extensive gardens; and about Deptford hundreds of acres are laid out in asparagus beds. Great quantities of peas are also raised for the London market on the line of road from London to Rochester. Apples, pears, plumbs, and cherries are raised in orchards, and the produce sent to the London market. Cider is also made in considerable quantities. In some places hops, apples, cherries, and filberts may be seen growing together in the same grounds; the proportion is 800 hop hills, 200 filberts, and 40 apple or pear trees per acre. The hops last twelve years, the filberts thirty; after which the apples and pears require the whole ground. This is a very good arrangement, by which the land is constantly producing.

The cultivation of the filberts is peculiar to Kent, and very well managed there, especially in the neighbourhood of Maidstone. They do not require a very rich soil, but grow well in that which is rocky and gravelly. The ground is kept clean around the trees, which stand about 12 feet apart. They are very carefully pruned, and one stem only is left to branch out a few inches above the ground; the branches are trained and pruned in the shape of a punch-bowl, and are not allowed to run above 4 or 5 feet high: thus they will bear abundantly, and be very profitable. When the filberts are gathered, they are laid to dry in the sun or under a shed exposed to the air. If they are well dried, they will keep good for several years.

There are still some extensive woods in Kent, but they are diminishing every year; and the produce of bark and timber is much reduced from what it formerly was. The demand for hop-poles has caused more attention to be paid to underwood; and some of the coppices, which are well managed, give a sufficient return to prevent their being grubbed up and converted into arable land.

On a general review of the agriculture of this county, it may be observed, that notwithstanding its present productive state, and the natural fertility of many parts, it is capable of very great improvement, and that by a little attention, and a judicious outlay of capital in draining and liming where it is required, and especially by a more economical application of agricultural labour, both in men and horses, its produce might be greatly increased, and raised at much smaller expense than it is at present.

Divisions, Towns, &c.—Kent has been long divided into five lathes. These divisions, in the opinion of some writers, take their name from the Saxon ȝe-laðian, to assemble; they had formerly distinct courts superior to the hundred courts; each of them comprehends several hundreds, and other smaller divisions. The lathes are as follows:—

I. *Sutton-at-Hone Lathe* occupies the western extremity of the county. It is bounded on the north by the Thames, on the west by Surrey, on the south by Sussex, and on the east by an irregular line drawn from the Thames just above Northfleet to the border of the county near Penshurst. It comprehends an area of 173,440 acres, and had in 1831 a population of 135,951. It includes the following hundreds:—

1. Axton (or Axtane, or Clackstone), Dartford, and Wilmington; 2. Blackheath; 3. Bromley and Beckenham; 4. Codsheath; 5. Little and Lesnes or Lessness; 6. Ruxley; 7. Somerden; 8. Westerham and Eatonbridge.

II. *Aylesford Lathe* is on the western side conterminous with Sutton-at-Hone Lathe; on the north it is bounded by the Thames, on the south by Sussex, and on the east by a line drawn from the Medway at Rainham below Chatham, south-east to Otterden near Charing, from thence south-west to the neighbourhood of Headcorn, in the Weald, from thence north-west along the Beult to the junction of a stream flowing from the Teise, and from thence south along that stream and along the Teise to the Sussex border at Lamberhurst. It comprehends an area of 244,150 acres, and had in 1831 a population of 134,176. It is subdivided into the following hundreds:—

9. Brenchley and Horsmonden; 10. Chatham and Gillingham; 11. Eythorne, or Eyhorne; 12. Hoo; 13. Larkfield or Lavercefield; 14. Littlefield; 15. Maidstone; 16. Shamwell, or Shamel; 17. Toltingtrough, or Toltingtrow; 18. Twyford; 19. Washlingstone, or Watchlingstone; 20. Wrotham; beside the liberty of the city of Rochester, and the liberty of the Lowy of Tonbridge.

Hasted adds to the above West or Little Barnefield hundred, containing part of the parish of Goudhurst, but not the church.

III. *Scray Lathe* is on the western side conterminous with Aylesford Lathe. On the north it is bounded by the Thames, on the south by Sussex, and on the east by a tolerably regular line drawn from Sea Sâlter near Whitstable to Aldington Corner, six miles west of Hythe; and from thence by Orlestone and Appledore to the eastern end of Oxney Isle. It comprehends an area of 260,510 acres, and had in 1831 a population of 78,973. It includes the following hundreds:—

21. Barnfield (East); 22. Barclay, or Barkley; 23. Blackbourne, or Blacetune; 24. Boughton-under-Blean, or Bocton; 25. Calehill; 26. Chart and Longbridge; 27. Cranbrook; 28. Faversham; 29. Felborough, or Feleborg; 30. Marden; 31. Milton, or Middleton; 32. Rolvenden; 33. Selbrittenden; 34. Tenterden; 35. Teynham; 36. Wye.

The Liberty of the Isle of Sheppey is a part of Milton hundred, but has a constable of its own. According to Hasted, Chart and Longbridge, Calehill, Felborough, and Wye hundreds have long been detached from the Lathe of Scray, and annexed to that of Shipway or Shepway; but all our other authorities give them as being still included in Scray.

IV. *St. Augustine Lathe* (formerly called also *Hedclinth Lathe*) is conterminous on the west with Scray Lathe. On the north and east it is bounded by the sea; on the south it is conterminous with Shepway Lathe; the boundary line being drawn from the border of Scray Lathe, near the town of Wye, to Ewell near Dover, and from thence south to the sea at Hougham, between Dover and Folkestone. Its area is 166,760 acres, and it had in 1831 a population of 103,621. It comprehends the following hundreds:—

37. Bewsborough; 38. Bleangate, or Blengate; 39. Bridge and Petham; 40. Cornilo; 41. Downhamford; 42. Eastry, or Estrege; 43. Kinghamford; 44. Preston; 45. Ringslow, or Tenet, comprehending the Isle of Thanet; 46. Westgate; 47. Whitstable; 48. Wingham.

V. *Shepway* or *Shipway Lathe* is conterminous on the north with St. Augustine Lathe, and on the west with Scray Lathe and the county of Sussex, and is bounded on the other sides by the sea. Its area is 127,380 acres; its population in 1831 was 25,849. It contains the following hundreds:—

49. Aloesbridge; 50. Folkestone; 51. Ham; 52. Hayne, or Heane; 53. Hythe; 54. Langport; 55. Loningborough; 56. St. Martin Pountney; 57. Newchurch; 58. Oxney; 59. Stouting; 60. Street; 61. Worth; besides the franchise and barony of Bircholt, called a hundred by Hasted.

There are several parts of the county which have their particular 'liberties,' exempt from the jurisdiction of the county magistrates. They are as follows:—I. The county of the city of Canterbury, in St. Augustine Lathe. II. The city of Rochester, and—III. The borough of Maidstone, both in Aylesford Lathe. IV. The Liberty of Romney Marsh, comprehending the hundreds of Langport, St Martin Pountney, and Worth, and part of the hundreds of Aloesbridge, Newchurch, and Street, and of the barony of Bircholt, all in Shepway Lathe. The Marsh is under the jurisdiction of its own bailiff and jurats. V. The Liberty of the Cinque-Ports, which is partly in this county and partly in Sussex. The part which is in this county comprehends—1. Sandwich, including the borough of Sandwich; the ville of Sarr, in the parish of St. Nicholas, and the ville of Ramsgate, in the parish of St. Lawrence, in the Isle of Thanet; the town and parish of Deal, the parish of Walmer, and part of that of Woodnesborough, near Sandwich; and the parish of Fordwich, near Canterbury, all in St. Augustine Lathe: 2. Dover, including the town of Dover, with part of the neighbouring parishes of Charlton and Hougham, the parish of Ringswould, between Dover and Deal, and the town and parish of St. John, Margate:

the parishes of Birchington, St. Peter's, and Wood, or Woodchurch, in Thanet; the town and part of the parish of Folkestone, in Shepway Lathe; and the town and part of the parish of Faversham, in Scray Lathe. All these, except Faversham and Folkestone, are in St. Augustine Lathe: 3. Hythe, including the town and parish of Hythe, and part of the parish of West Hythe, in Shepway Lathe: 4. New Romney, including the town and parish of New Romney, part of the parishes of Old Romney, Appledore (in Scray Lathe), Brenzet, Ivechurch or Ivychurch, Snargate and part of Bromhill, all near Romney, and, except Appledore, in Shepway Lathe: 5. Rye, the liberty of which includes in this county the town of Tenterden, in the Lathe of Scray. [CINQUE-PORTS.]

The Liberty of Hastings formerly included in this county the parish of Beaksbourn, near Canterbury (St. Augustine Lathe), and the hamlet or ville of Grange, or Grench, in Gillingham parish, near Chatham, in Aylesford Lathe: but these were separated from it by the statute 51 Geo. III., c. 36.

Several other places, though not out of the jurisdiction of the county magistrates, are not under the constables of the hundred, but have constables of their own.

There are in the county two cities, Canterbury and Rochester; the Cinque-Ports of Dover, Hythe, New Romney, and Sandwich; the parliamentary boroughs of Greenwich (including Deptford and Woolwich), Chatham and Maidstone, and eighteen other market-towns, viz. Ashford, Bromley, Cranbrook, Dartford, Deal, Faversham, Folkestone, Gravesend, Lydd, Margate, Milton, Ramsgate, Sevenoaks, Sheerness, Sittingbourne (held monthly), Tenterden, Tonbridge or Tunbridge, and Westerham. There is a market held at long intervals at Eleham, or Elham, on the Lesser Stour, in order to prevent the forfeiture of the charter; and there were formerly markets at Aylesford, St. Mary Cray, Eltham, Goudhurst, Lenham, Town Malling, Queenborough, Smarden, Wrotham, and Wye. Of some of these places an account is given elsewhere. [ASHFORD; AYLESFORD; CANTERBURY; CHATHAM; DEAL; DOVER; GREENWICH (under which Deptford is included); MAIDSTONE; MARGATE; RAMSGATE; ROCHESTER; SANDWICH; SHEERNESS; WOOLWICH.] The others we shall notice here.

Hythe is locally in Hythe hundred, in the lathe of Shepway, 65 miles from London. It is called in antient records Hethe, and in Domesday Hede, from the Saxon hyð, a haven. This town is supposed to owe its origin to the decay of West Hythe and Lympne, or Limne (the Portus Lemanis of the Antonine Itinerary), which are now both inland. It was early a place of importance, being one of the Cinque-Ports, and having once had, according to Leland, a fair abbey and four parish churches. In the reign of Henry IV. the inhabitants of this town experienced such heavy calamities, pestilence, conflagration, and shipwreck, that they contemplated abandoning the place; but the king by the grant of a liberal charter induced them to remain. The parish of St. Leonard, Hythe, which coincides with the Cinque-Port, contains 860 acres, and had in 1831 a population of 2287, of which scarcely any part was agricultural. The town, which is at the foot of a steep hill or cliff, about half a mile from the shore, consists chiefly of one long street, parallel to the sea, with some smaller ones branching from it, or parallel to it. The townhall and market-place are in the centre of the town. The church is on the slope of the hill above the town; it is a cross church, very antient, with a west tower. Some of the western part of the church is of Norman architecture: the eastern part is early English, of remarkably good design and execution; this part of the church has bold buttresses, and under it a remarkably fine groined crypt. There are two hospitals, or almshouses, in Hythe, of antient foundation. There are barracks at the east end of the town, a small theatre, and a public library and reading-room. The market is on Saturday. The corporation of Hythe, under the Municipal Reform Act, consists of four aldermen or jurats, and twelve councillors. Hythe formerly returned two members to parliament, by the Reform Act it sends only one. The parliamentary borough includes the municipal borough, the Liberty of the town of Folkestone, and the parishes of West Hythe, Saltwood, Cheriton, and Folkestone, and part of that of Newington. These limits include the watering-place of Sandgate. The living of Hythe is a perpetual curacy united with the rectory of Saltwood; their joint annual value is 784*l.*, with a glebe-house; they are in the diocese of Canterbury, but exempt from the archdeacon's visitation. There were in 1833 in the parish ten day-schools with 197 children; two day and Sunday national schools with 238 children, and two Sunday-schools with 137 children.

About a mile north of Hythe are the ruins of Saltwood castle; the outer walls, which are partly remaining, enclose an elliptical area of three acres. These walls were strengthened by several square or circular towers, now much dilapidated. The keep, or gate-house, which was almost entirely rebuilt by Courtenay, archbishop of Canterbury, in the time of Richard II., is now occupied as a farm-house.

New Romney, in the lathe of Shepway, is situated near the sea, in Romney Marsh, and is 70 miles from London. The name appears to be of Saxon origin. The etymology given by Lye is Rumen-ea, from Rume, wide, spreading, *q.d.* the spreading water or marsh. Perhaps it may be from Rumen-eze, 'the island in the flat or marsh,' a spot sufficiently elevated from the surrounding marsh to be dry being termed an island, or 'ey,' by the Saxons. New Romney appears to have risen before the time of Edward the Confessor, from the decay of Old Romney (more inland), the haven of which was deserted by the sea. The haven of New Romney being commodious and well frequented, the town became important, and was made one of the cinque-ports, perhaps in the place of Old Romney, which, with Lydd, Denge Marsh (extending to Denge Ness), and Oswardestone, were added to it as subordinate members. But the Rother, which then entered the sea at this place and formed its harbour, having forsaken its channel (in the reign of Edward I.), the harbour was choked up with beach, and the town went to decay. In its flourishing time it is said to have been divided into twelve wards, and to have had five parish churches, as well as a priory and an hospital, of both which there are some remains. At present it is an insignificant place, built on a soil of gravel and sand, slightly elevated above the surrounding country. It consists chiefly of one wide well-paved street, with a market-house and a hall, or brotherhood-house, in which the mayor, jurats, and commons of the Cinque-Ports frequently hold their sittings. There is a weekly market and one yearly fair. The parish comprehends 2320 acres, and had, in 1831, a population of 983. The church is a very antient and handsome building. The lower part of the tower and part of the nave are of Norman architecture and of good composition; the upper part of the tower is of early English, and the remaining part chiefly of decorated English character, with large and fine windows. The living is a vicarage in the diocese of Canterbury, exempt from the archdeacon's visitation, of the clear yearly value of 161*l.*, with a glebe-house not fit for residence, in the gift of All Souls' College, Oxford.

There were, in 1823, two infant or dame schools, with 26 scholars, two day-schools with 50 scholars, and one national day and Sunday school with 142 children. Up to the passing of the Reform Act, Romney returned two representatives to the House of Commons; these, like the other members for the Cinque-Ports, were styled 'barons.' The first return of members from the town was in the reign of Edward I. It was disfranchised by the Reform Act; and is one of the polling-places for East Kent.

At the village of Dymchurch, about four miles north-east of New Romney, along the shore of Romney Marsh, is a sea-wall or embarkment of earth more than three miles in length, by which the marsh is preserved from the inundation of the sea. It is called Dymchurch wall. Its perpendicular height varies from fifteen to twenty feet above the general level of the marshes: at the side next the sea it has a slope of a hundred yards: the width of the top varies from fifteen to thirty feet. There are sluices through it for draining the marshes. Old Romney, from the decay of which New Romney arose, is now a mere village with a population of 113 persons.

Bromley is in Bromley and Beckenham hundred, in the lathe of Sutton at Hone, and near the Ravensbourne River, 10 miles from London Bridge. Bromley parish contains 4630 acres, and had in 1831 a population of 4002. The town consists principally of one street, with neat well-built houses, and having a market-house in the middle of the town supported on wooden pillars. The church contains the monuments of Dr. Hawkesworth, Dr. Zachary Pearce, bishop of Rochester, and several others. The bishop of Rochester's palace at Bromley is a plain brick mansion, rebuilt A.D. 1777. In the palace garden is a chalybeate

spring, 'St. Blaise's well,' of some repute. There is a well-endowed hospital or 'College,' founded in 1666 for clergymen's widows, and since much enlarged: there are now forty widows in the establishment. The buildings surround two quadrangular courts: there is a chapel, and a chaplain is attached to the foundation. There are some dissenting meeting-houses. There is a market on Thursday, at which, on the third Thursday in each month, much business is done in cattle; there are also two cattle fairs. The living of Bromley is a perpetual curacy in the diocese and archdeaconry of Rochester, and in the gift of the dean and chapter of the cathedral of that see: its clear yearly value is 160*l.* There were in Bromley, in 1833, two day and Sunday national-schools, one with 100 boys, and another with 90 girls; 15 children of each sex were clothed from an antient endowment. Bromley is one of the polling-places for the western division of the county of Kent.

Cranbrook, the principal town in the Weald of Kent, is in the hundred of Cranbrook in the lathe of Scray, 48 miles from London Bridge. The parish comprehends 10,460 acres, and had in 1831 a population of 3844, about half agricultural. The town of Cranbrook is irregularly built. The church is a large and handsome edifice in the perpendicular style, with good buttresses and fine windows; it is advantageously situated on a small eminence near the centre of the town. There are several dissenting meeting-houses. Cranbrook was once the centre of the clothing trade introduced by the Flemings, whom the policy of Edward III. induced to settle in this country. Since the removal of this branch of industry to the north and west of England, Cranbrook has been a mart for the agricultural produce of the neighbourhood, especially hops. The market, which is now held on Wednesday, is chiefly for corn and hops; every fortnight there is a cattle-market. The living is a vicarage in the diocese and archdeaconry of Canterbury, of the clear annual value of 163*l.*, with a glebe-house. There were, in 1833, eleven day-schools (two of them endowed) with 299 scholars; and six Sunday-schools with 449 children. In the parish of Cranbrook are the ruins of Sissinghurst, a fine mansion formerly the residence of the Baker family. From having been used as a French prison during one of the wars of the last century, it acquired the inappropriate name of Sissinghurst Castle. In the hamlet of Milkhouse Street, in this parish, are the remains of an antient chapel dedicated to the Holy Trinity. Cranbrook is one of the polling stations for the western division of the county.

Dartford is in the hundred of Axton, Dartford, and Wilmington, in the lathe of Sutton-at-Hone. It is on the river Darent, from which it gets its name (in Saxon Darentford, in Domesday Tarenteford), about three miles from its junction with the Thames, 15 miles from London Bridge on the road to Dover. The great insurrection under Wat Tyler, in the reign of Richard II., broke out here. The parish contains 4150 acres, and had, in 1831, a population of 4715, about one-tenth agricultural. The town is in a narrow valley, and the principal street is on the line of the Dover road. The church is near the east end of the town, close to the bridge over the Darent. The antient burying-ground is at some distance eastward from the church, on a hill which overlooks the town; a new burial-ground was consecrated a few years since. There are several dissenting places of worship. The trade of Dartford is considerable: there are chalk-pits near the town, and corn, oil, powder, and paper mills in the neighbourhood on the river Darent; also a large iron foundry and manufactory of machinery.

The first paper-mill erected in this country was at Dartford; it was built by Sir John Spielman, a German, who introduced the manufacture, and stood on the site of the present powder-mills: the first mill established in England for rolling and slitting iron was also near Dartford. Barges from the Thames come up to the wharf below the town. The market is on Saturday; and there is a yearly fair. The trade in corn is considerable. The living of Dartford is a vicarage in the diocese and archdeaconry of Rochester, of the clear yearly value of 534*l.* with a glebe-house. There were, in 1833, nine day-schools with 311 children; one of these, with 80 scholars, is endowed: there were two day and Sunday national schools with about 200 children; and three Sunday-schools with 166 children.

Near the town are the ruins of a nunnery, founded A.D. 1371, by Edward III., for Augustine nuns, but afterwards occupied by Dominican nuns. At the dissolution the prioress and several of the nuns were of some of the best and most antient families of the county: the revenues were then 400*l.* 8*s.* gross, or 380*l.* 9*s.* 0½*d.* clear. The buildings were occupied by Henry VIII., and, during her progress in Kent, by Queen Elizabeth, as a royal residence. The present remains are of brick and consist of a large embattled gate way, with some adjacent buildings, now occupied as a farm-house: the gardens and orchards occupied twelve acres, and were surrounded by a stone wall yet entire. There is an almshouse at Dartford, formerly an hospital for lepers.

Faversham is locally situate in the hundred of Faversham in the lathe of Scray, but has a separate jurisdiction, being a member of Dover, one of the Cinque-Ports. It is on a stream running into the East Swale, and just to the left of the road to Dover, 47 miles from London Bridge. It appears to have been a place of some note before the time of Stephen, who built and endowed here an abbey for Cluniac monks, in which himself, his queen Matilda, and his eldest son Eustace of Boulogne were buried. This abbey was at the time of the dissolution in the hands of the Benedictine order: its revenue was 355*l.* 15*s.* 2*d.* gross, or 286*l.* 12*s.* 6¾*d.* clear. Some portions of the outer walls remain. At the dissolution the remains of King Stephen were thrown into the river, for the sake of the leaden coffin in which they were contained.

The parish of Faversham comprehends 2270 acres, and had in 1831 a population of 4429, less than one-tenth agricultural. The population of the adjacent parish of Preston, a village which joins Faversham town, was at the same time 675. The town, which has been much improved in the last half century, consists principally of four streets forming an irregular cross, and having the guildhall and market-place in the centre. The church, which is a large cruciform structure of flint, has some portions in the decorated English style; other portions are of later date. There is a light tower at the west end, crowned with pinnacles, and surmounted by an octagonal spire. There are an assembly-room and a theatre. Faversham is a port, and has an excise-office and custom-house. The creek or arm of the Swale on which the town stands is navigable for vessels of 150 tons, several coasting vessels belong to the port. Coals from the North of England and timber from the Baltic are imported. The exports are chiefly agricultural produce, corn, hops, fruit, and wool, which are sent to London by hoys. There is no manufacture now except of gunpowder and cement on a small scale. The oyster fishery, which is an important branch of industry, employs about 250 adult males. The oyster fishermen and dredgermen form an incorporated company. The markets are on Wednesday and Saturday: there are a monthly cattle-market and an annual fair. The council of the borough of Faversham, under the Municipal Reform Act, consists of four aldermen or jurats and twelve councillors. The living is a vicarage in the diocese and archdeaconry of Canterbury, of the clear yearly value of 342*l.*, with a glebe-house. There were in 1833 a well endowed grammar-school, with 12 scholars; a national school with 185 children; and twenty-one other day-schools, with 640 children; two boarding-schools with 105 children; and three Sunday-schools with 452 children. There are several dissenting meeting-houses.

Folkestone is locally in the hundred of Folkestone in Shepway lathe, 70 miles from London, but has separate jurisdiction, being a member of the Cinque-Port of Dover. It was early a place of some importance: the Romans had a tower here on a high hill, of the earth-works or entrenchments of which there are yet some remains. By the Saxons it was called Folcestane; in Domesday, Fulchestan. There was a monastery, which had been destroyed by the Danes during or before the time of Athelstan. There was also a castle built by the Saxon kings of Kent, and rebuilt by the Normans, which has been in later times nearly all destroyed, with the cliff on which it stood, by the encroachments of the sea. All that remains is a small part of the wall near the church.

The parish of Folkestone comprehends in all 4360 acres, of which 680 are in the separate jurisdiction of the town: the population in 1831 consisted of 4296 persons, of whom 3638 were in the town. Folkestone is situated on the shore of the English Channel, partly in a hollow between two cliffs, and partly on the west cliff. The streets are narrow, steep, and indifferently paved. The harbour, owing to the accumulation of shingle, is not capable of affording anchorage to many vessels. Many boats belong to it, which are engaged in the mackerel and herring fisheries. The church,

which stands at the west end of the town, is a cross church of early English character, having a tower in the centre supported by strong piers. The western end was partly blown down by a hurricane in December, 1705, and when rebuilt the dimensions were contracted. There are three dissenting places of worship. There was a Benedictine priory at Folkestone, originally alien, but afterwards made denizen. A gateway in the wall and some part of the foundations are all that remain of this building. The trade of the town is dull: fishing and smuggling are both on the decline. The market is on Thursday, and there is one yearly fair. The council under the Municipal Reform Act consists of four aldermen or jurats and twelve councillors. The market-house and the guildhall have been lately rebuilt. The living is a perpetual curacy, in the diocese and archdeaconry of Canterbury, of the clear yearly value of 185*l*. There were, in 1833, one infant-school, with 60 children; twelve dame-schools, with 251 scholars; six day or boarding and day schools, with 242 children; and four Sunday-schools, with 491 children. Dr. William Harvey was born at Folkestone.

Folkestone was by the Reform Act made part of the parliamentary borough of Hythe.

The village of Sandgate, which is partly in Folkestone parish, is a place of some resort as a bathing-place. There is a castle at Sandgate, built by Henry VIII., probably on the site of a more antient one.

Gravesend is on the south bank of the Thames, locally in the hundred of Toltingtrough, in the lathe of Aylesford, 22 miles from London Bridge through Dartford. The western part of the town is in the parish of Gravesend, the eastern in that of Milton. In the time of Richard II. Gravesend was burned, and most of the inhabitants carried into captivity by a squadron of French galleys. In the reign of Henry VIII. two platforms were raised for the protection of the town, and a blockhouse at Tilbury, in Essex, to guard the passage of the river.

The parish of Gravesend comprehends 630 acres, with a population, in 1831, of 5097; Milton contains 650 acres, with a population of 4348: making together 1280 acres, with a population of 9445. Gravesend has of late years become a great place of resort for visitors from the metropolis, and has been much enlarged and improved: the old town is however still mean and irregular. Two piers have been erected for landing passengers, and a convenient bathing-house for visitors. There are a library, concert-room, theatre, and gardens. The country round Gravesend is pleasant, and the view from the Windmill Hill, above the town, extensive. The church, which is near the centre of the town, is a neat spacious brick building: there are a chapel of ease and several dissenting places of worship. Milton church is near the east end of the town.

Formerly vessels sailing from the port of London were obliged to stop at Gravesend to take their clearances. Outward-bound Indiamen still take in fresh provisions here: seamen going out provide themselves with slops. There are considerable lime-works and brick-fields about the town, and a great quantity of land in the neighbourhood is occupied by market-gardeners, who raise vegetables, especially asparagus, for the supply of the London markets. Many vessels are employed in fishing; and some rope-making and ship-building are carried on. The resort of visitors from the metropolis to Gravesend during the summer season is very great, owing to the cheapness of steam-boat conveyance and its convenient distance from London. The market is on Wednesday and Saturday, the former for corn. The canal which unites the Medway and the Thames enters the latter near Gravesend. This town is one of the polling-places for West Kent. There is a fort at Gravesend, mounting sixteen guns.

The living of Gravesend is a rectory, of the clear yearly value of 307*l*.; that of Milton a rectory, of the clear yearly value of 359*l*.; both of them are in the diocese and archdeaconry of Rochester.

The inhabitants of the parishes of Gravesend and Milton were incorporated by Queen Elizabeth. By the Municipal Reform Act the borough was divided into two wards: it has 6 jurats or aldermen and 18 councillors. There were, in 1833, in the two parishes, two infant or dame schools, with 74 children; two national schools, with 180 children; one endowed day-school, with 34 children; seventeen other day-schools, with 449 children; seven boarding-schools, with 165 children; and four Sunday-schools, with 559 children.

Lydd, or Lid, is in the hundred of Langport, in the lathe of Shepway. The hundred is one of those included in the liberty of Romney Marsh; but Lydd is a corporate town, and a member of the cinque-port of New Romney, from which it is distant about three miles. The name is written in antient records Hlyda, and is supposed to be a corruption of the Latin *littus*, 'a shore,' a name corresponding to its situation. It is upon the tongue of land, the termination of which is Denge Ness, about two miles from the sea; but it is probable that the sea once came nearer to it. The parish comprehends 11,660 acres, with a population, in 1831, of 1357, more than half of which was agricultural. The town consists of houses irregularly built on an open flat, and from its being quite out of any thoroughfare, and from the decline of the contraband trade, by which it was formerly supported, it is a dull decayed place. The church is a large building, with a fine tower in the perpendicular style, and crocketted pinnacles. The market is on Thursday: the chief employment of the townsmen is in fishing. The corporation, which is left untouched by the Municipal Reform Act, consists of a bailiff, jurats, and freemen. The bailiff and jurats are justices in the borough, which is co-extensive with the parish. The living is a vicarage, in the diocese of Canterbury, exempt from the archdeacon's visitation, of the clear yearly value of 1247*l*., with a glebe-house. There was, in 1833, only one school in the parish, a national school, of 116 children, with a lending library attached.

On the point of Denge Ness is a lighthouse 110 feet high, and a small fort. There is a spring of fresh water on this point, which is covered by the sea every tide.

Milton, sometimes distinguished as Milton-next-Sittingbourne, is in the hundred of Milton and in the lathe of Scray, on a creek or arm of the Swale, 39½ miles from London.

This town was a demesne of the Saxon kings, who are said to have had a palace in the neighbourhood. In the struggle of the Danish chieftain Hastings with Alfred the Great, the Danes formed an encampment here, the remains of which yet exist, under the name of Castle Rough, from its being overgrown with trees and underwood. The town was burned by Earl Godwin during his quarrel with Edward the Confessor, but rose to importance again in the time of the Conqueror. The parish comprehends 2340 acres, and had, in 1831, a population of 2233, of which about an eighth is agricultural. The town is on the side of a hill sloping down to the creek, and is ill built. The business of the place arises from its oyster fishery, and from its being the port of communication with London for the surrounding agricultural district. In the centre of the town is the antient court-house for holding the manor courts and public meetings, with the town gaol beneath. The market is on Saturday, and there is one yearly fair. Much corn is shipped here. The church, which is to the north of the town, is chiefly in the decorated English style; it is large and handsome, with an embattled tower at the west end. The living is a vicarage in the diocese and archdeaconry of Canterbury, of the clear yearly value of 256*l*. with a glebe-house.

There were in the parish, in 1833, seven infant or dame schools, containing 140 children; three day-schools, with 163 children; one day and Sunday national school, with 150 children, partly supported by endowment; and one Sunday-school, with 152 children.

Sevenoaks, in the hundred of Codsheath and the lathe of Sutton-at-Hone, is on the Hastings road, 24 miles from London. This town, called in an antient document Seovanacca, received its name from seven oak trees which once occupied the eminence on which the town stands. The parish comprehends an area of 6790 acres (of which 1910 are in the liberty of Riverhead, and 3210 in the Weald liberty), with a population of 4709; about one-third agricultural. The town is situated on the northern brow of the chalk marl and greensand range of high lands, in the midst of a fertile and well cultivated district. It is well built, and contains a number of good houses. The church is spacious and elegant, and, from its situation on an eminence, forms a conspicuous object; it is chiefly in the perpendicular style. There are several dissenting meeting-houses. At the south end of the town is the grammar-school, which has a good endowment: there is also a large range of almshouses; both these institutions owe their origin to Sir William de Sevenoke, a foundling brought up by some charitable persons in this town, from which he

took his name. There are two other well endowed schools, founded by Lady Margaret Boswell, with a handsome school-house lately rebuilt. The market-house is an old building, in which the county assizes were held frequently during the reign of Elizabeth and occasionally since. The market is on Saturday, chiefly for corn; there is a monthly cattle-market; and also two yearly fairs. There are some silk-mills in the neighbourhood. The living is a vicarage and sinecure rectory, in the peculiar jurisdiction of the archbishop of Canterbury, of the clear yearly value of 935*l.*, with a glebe-house.

Near Sevenoaks is Knowle Park, the seat of the Earl of Plymouth.

There were, in 1833, in Sir William de Sevenoke's grammar-school 31 boys (11 on the foundation); in Lady Boswell's schools, 215 children of both sexes; and in thirteen other day or boarding and day-schools, 408 children. There were four Sunday-schools, with 397 children, three of them with lending libraries attached.

Sittingbourne is in the hundred of Milton and the lathe of Scray, 40 miles from London on the road to Canterbury. The parish contains 1260 acres, and had, in 1831, a population of 2182, about one-eighth agricultural. It consists chiefly of one main street. There are some good inns, and the prosperity of the place depends in a great degree on the passage of travellers between London and Dover. The church is a spacious edifice, rebuilt, with the exception of the tower and the external walls, since A.D. 1762, when it was accidentally burnt. It has some curious windows of decorated character, and some fine ones of perpendicular date. Queen Elizabeth granted, in two successive charters, a weekly market and two fairs· she also incorporated the town, and granted the privilege of returning members to parliament. Communication with London is maintained by hoys from a quay on Milton creek in this parish. The weekly market has been long discontinued, the fairs remain, and the other privileges were never exercised. The present market is held monthly. The living is a vicarage in the diocese and archdeaconry of Canterbury, of the clear yearly value of 212*l.*, with a glebe-house. There were, in 1833, two dame-schools, with 29 children; nine boarding and day schools, with 186 children; one national school, with 160 children; and one Sunday-school, with 233 children. Sittingbourne is one of the polling-places for East Kent.

Tenterden is locally in the hundred of Tenterden and lathe of Scray, but has a separate jurisdiction, being a member of the cinque-port of Rye. It is 55 miles from London, on the road through the Weald of Kent to Romney. The parish comprehends 8620 acres, and had, in 1831, a population of 3177, about half agricultural. The town stands on an eminence, in a rich agricultural district, upon which it depends: it consists of one main street along the Romney road, and contains some good houses. The church is a spacious and handsome edifice, chiefly of perpendicular character, having a lofty tower at the west end, to which a beacon was formerly attached. It has been a popular saying that 'Tenderden steeple was the cause of Goodwin Sands.' This has been supposed to originate from the circumstance of the funds destined for keeping up Sandwich haven having been applied to the building of this church. There are some dissenting places of worship. There is a townhall, a modern building, sometimes used as an assembly-room. The market is on Friday, and there is a yearly fair. When the clothing trade was carried on in the Weald of Kent, this town was one of the manufacturing places. Tenterden was incorporated by Henry VI. The corporation, under the Municipal Reform Act, consists of 4 jurats or aldermen and 12 councillors. The living is a vicarage, in the diocese and archdeaconry of Canterbury, of the clear yearly value of 177*l.* There were, in 1833, a national school, with 190 children, endowed with the transferred funds of a decayed grammar-school; six other day-schools, with 127 children; and four Sunday-schools, with 181 children.

Tunbridge, or Tonbridge, is in the liberty of the Lowey of Tunbridge, and in the lathe of Aylesford, 30 miles from London, on the road to Hastings. In the time of the Conqueror a castle was built on this spot on the banks of the Medway by Richard Fitz-Gilbert (otherwise Richard de Tunbridge), afterwards earl of Clare; and the town rose under the protection of the castle. In the civil troubles of the reign of Henry III. the castle was besieged and taken from its owner Gilbert Rufus, earl of Clare, Glo'ster, and Hertford, by Prince Edward. During the siege the garrison burnt the town. There was also a priory at Tunbridge founded by Richard de Clare, first earl of Hertford, in the time of Henry I., for canons of St. Augustin, the revenue of which at the suppression was 169*l.* 10*s.* 3*d.* The parish comprehends 14,730 acres, and has a population of 10,380, about one-fourth agricultural. The town consists chiefly of one street, broad, partially paved, and, from its being on a declivity, clean. There are several bridges over the Medway, which is here divided into various arms. Near the principal bridge is a wharf, where the timber brought from the Weald is sent down the Medway. The church, which is near the centre of the town, is a large and handsome fabric, in various styles of architecture. There is a free-school, founded by Sir Andrew Judd, and richly endowed: it has 16 exhibitions of 100*l.* per annum each, tenable at any college of Oxford or Cambridge, besides thirteen other exhibitions, and a fellowship at St. John's College, Oxford. There are a townhall and market-house. The ruins of the castle, which are near one of the bridges, consist of an entrance gateway, flanked with round towers, and tolerably perfect, and of the artificial mound on which the keep stood; the outer walls enclosed an area of six acres. The ruins of the priory consist principally of the refectory, now converted into a barn. There is a weekly market on Friday, and a monthly cattle-market, also one yearly fair. The trade of the town is in coal and timber brought from Maidstone for the supply of the neighbourhood: gunpowder and wooden wares (which last take their name from the town) are made to a small extent. The living is a vicarage in the diocese and archdeaconry of Rochester, of the clear yearly value of 763*l.*, with a glebe-house.

There were in 1833 seven infant or dame schools, with 272 children; Judd's endowed grammar-school, with 100 boys (60 of them on the foundation); the 'Southborough Free-school,' with 57 children; and fourteen other boarding and day schools, with 430 or 440 children; four day and Sunday schools of the established church (two of them national schools), with 382 children, and three Sunday-schools with 420 children.

Tunbridge Wells is between five and six miles south of Tunbridge, upon the border of Kent and Sussex, part of it being in each county. It extends into the parishes of Speldhurst (Washlingstone hundred, lathe of Scray), and Frant (Rotherfield hundred, rape of Pevensey, Sussex), but is chiefly in that of Tunbridge. The population cannot be given distinct from that of the parishes in which the town is situated. The chalybeate spring, to which the town owes its origin, was first noticed in the reign of James I., by Dudley lord North, who had been residing in the neighbourhood for the recovery of his health. The benefit which he derived from the water brought the spring into notice; the wells were sunk, paved, and enclosed, but the visitors found accommodation at Tunbridge town. The water is chalybeate, and nearly equal in strength to that of Spa, in Germany. The soil is dry, and the air of the place is healthy, though cold. When Henrietta, queen of Charles I., visited the Wells, she and her suite remained under tents. By degrees however permanent habitations were erected in the immediate vicinity of the wells, and at the neighbouring villages of Southborough and Rusthall. After the Restoration the place rapidly increased. A chapel was built at Tunbridge Wells dedicated to King Charles the Martyr; a subscription-school was also established, and an assembly-room, coffee-house, bowling-greens, and other places of amusement were erected in the neighbourhood. The town has much increased of late years. The Wells, properly so called, are in the centre of the town, and near them are the markets, the chapel, the assembly-rooms, and the public walks, or parades. There are a theatre, libraries, and the other usual requisites of a watering-place. Different groups of houses are distinguished by the names of Mount Zion, Mount Ephraim, Mount Pleasant, and Bishop's Down. About a mile and a half south-west from the Wells, in the county of Sussex, are the High Rocks, which present a striking and romantic scene. The chapel at Tunbridge Wells has been enlarged since its first erection, and stands partly in each of the three parishes. There is a new church lately erected in Tunbridge parish, and there are some dissenting meeting-houses. Tunbridge Wells is famous for toys and small articles turned in holly, plum-tree, cherry-tree, sycamore, and various foreign woods.

Southborough is midway between Tunbridge town and

the Wells. A new district church has been erected here, and there is (as already noticed), an endowed free-school. The place consists of a number of scattered houses.

Westerham is in the hundred of Westerham, in the lathe of Sutton-at-Hone, 21 miles from London, through Bromley. It is near the source of the Darent, and in the valley of Holmesdale, between the chalk and the ragstone hills. The parish has an area of 5740 acres, and the population in 1831 was 1985, about two-fifths agricultural. The town is on a declivity; the principal street runs east and west on the road which runs from Maidstone along the valley of Holmesdale into Surrey. The church is a neat and tolerably spacious building, chiefly in the perpendicular style: it contains a neat cenotaph to the memory of General Wolfe. There are one or two dissenting places of worship. The market is on Wednesday, and there is a yearly cattle-fair.

The living is a vicarage united with the parochial chapelry of Edenbridge; they are in the diocese and archdeaconry of Rochester; their joint annual value is 608*l*., with a glebe-house. There were in 1833 a national school with 46 girls, and five other day-schools with 144 children; two boarding-schools with 45 children; and two Sunday-schools with 96 children.

General Wolfe and Bishop Hoadley were natives of Westerham.

Queenborough, or Quinborowe, is in the liberty of the Isle of Sheppey, in the lathe of Scray, 45½ miles from London, by a road branching from the Dover road eight miles beyond Chatham, and leading into the Isle by King's Ferry over the West Swale. Queenborough (antiently Cyningburg) belonged to the Saxon kings, who had a castle here, on the site of which Edward III. commenced a new and more extensive fortress. Edward made the town a free borough, and gave it the name of Queenborough, in honour of his consort Philippa. This castle was demolished in the time of the Commonwealth, but the moat and well point out its site. The well, after being partly filled up with rubbish, was cleared out and restored to use in 1725; it supplies the town with water. Queenborough is a poor place; the greater part of the inhabitants are dependent on the oyster fishery; a few of them possess boats of their own. The houses form one main street: the church was originally a chapel to the parish church of Minster, but is now parochial: the interior is neat. There is a guildhall and a small gaol under it. Queenborough has a corporation, and until disfranchised by the Reform Act it returned two members to parliament.

The parish had in 1831 a population of 786. The income of the corporation is derived from the oyster fishery, the management of which is in their hands. The markets, which are now disused, were held on Monday and Thursday. The living is a perpetual curacy in the diocese and archdeaconry of Canterbury, of the clear yearly value of 66*l*., with a glebe-house. There were in 1833 a free-school, with 72 children, five other day schools, with about 100 children, and two Sunday-schools, with 177 children.

St. Mary Cray, the most considerable of the villages which take their name from the river Cray (the others are St. Paul's Cray, Foot's Cray, and North Cray), in Ruxley hundred, Sutton-at-Hone lathe, is on a cross-road which connects the Maidstone and Hastings roads, 13 miles from London. It had formerly a market, but it was discontinued in 1703 in consequence of the market-house having been blown down. The population in 1831 was 905. Elham, or Eleham, is in Loningborough hundred, Shepway lathe, on the Lesser Stour. It was formerly a place of consequence, though now only a village. A market was granted by Henry III., and it is still held at intervals of five or six years in the market-house, which is yet standing, in order to maintain the charter. The church has a large tower of early English architecture, with a small leaden spire. Population in 1831, 1302. Eltham is in Blackheath hundred, Sutton-at-Hone lathe, eight miles from London on the Maidstone road. Here was a royal palace built at an early but unknown period. Henry III. kept Christmas here A.D. 1270. Most of the succeeding sovereigns frequently resided here till Henry VIII., but on the rise of Greenwich it was deserted. The principal part of the palace yet remaining is the antient hall, 100 feet long by 56 broad, and 60 high, now occupied as a barn or cow-house: the windows now bricked up have been extremely elegant: the roof is of timber curiously wrought and richly ornamented. The area of the palace is surrounded by a high stone wall, and a broad deep moat, now converted into a garden, over which are two bridges. Population in 1831, 2005, or including the hamlet of Mottingham, 2129. Goudhurst is partly in Marden and partly in Cranbrook hundred, in the lathe of Scray. The church, which is on a commanding eminence, is a spacious fabric, with a low massive western tower formerly crowned with a lofty spire. Goudhurst was formerly one of the clothing towns of the Weald, and had a weekly market. Population in 1831, 2758. Lenham is in Eyhorne hundred, in the lathe of Aylesford, on the road from Maidstone to Ashford and Folkestone. The market was discontinued early in the last century, and the attempts since made to revive it have failed. Population in 1831, 2197. Town Malling, otherwise West Malling, is in Larkfield hundred, lathe of Aylesford, 29 miles from London Bridge, just out of the Maidstone road. Here was an antient Benedictine nunnery, the yearly value of the possessions of which at the dissolution was 245*l*. 10*s*. 2½*d*. gross, or 218*l*. 4*s*. 2½*d*. clear. Many parts of the conventual buildings are yet standing, especially a portion of the west end of the church, a beautiful specimen of Norman architecture. There is also at St. Leonard's, a hamlet of Malling, a tower 71 feet high, much resembling the keep of a Norman castle; it belonged to St. Leonard's chapel, now destroyed. Town Malling church, a handsome and spacious building, has a Norman tower at the west end. There is a small endowed free-school. The market, held on Saturday, has not been long discontinued. Population in 1831, 1459. Smarden is in Calehill hundred, in the lathe of Scray, in the Weald. The market-house is yet standing. There are one or two dissenting meeting-houses and a small free-school. Population in 1831, 1177. Wrotham is in Wrotham hundred, in Aylesford lathe, 24 miles from London, on the Maidstone road. It lies near the foot of the chalk hills. The church is a large well-built edifice in a great mixture of styles. The market was held in the centre of the village at the intersection of the two principal streets. Population in 1831, 2601. Wye is in Wye hundred, in the lathe of Scray, about three miles north-east of Ashford under the chalk hills. Here was before the Reformation a college, the buildings of which, forming a quadrangle round an open court, are used for the purposes of two endowed schools. The market has been long discontinued. Population in 1831, 1639.

Besides the foregoing decayed market-towns, one or two villages claim notice. Lewisham in Blackheath hundred, in the lathe of Sutton-at-Hone, consists of a long street of good houses, extending about two miles along the Hastings road. There is a modern church near the centre of the town. There are a grammar-school and an English school, both endowed, and an almshouse. The chapelry of Sydenham is a part of Lewisham parish, which had in 1831 a population of 9659. Broadstairs on the coast, near the North Foreland, has risen into notice as a watering-place: it is in Ringslow or Thanet hundred, in St. Augustine lathe. A small pier for the protection of the fishing craft was antiently built here, and the passage down the cliff to the sea was defended by an arch, gates, and portcullis; the arch still remains. There are some remains of an antient chapel near the pier, which is now converted into a dwelling-house. There are many good houses at Broadstairs, with libraries, warm baths, and other accommodations. Many Roman coins have been found here. Minster, in the Isle of Thanet and Ringslow hundred, had an antient nunnery destroyed by the Danes. The church is antient, and chiefly of early English character: it is a cross church, with a tower at the west end. Minster in Sheppey (lathe of Scray), had also a very antient nunnery, whose yearly possessions at the dissolution were valued at 29*l*. 7*s*. 10¾*d*. gross. The gate-house and part of the church and chapel yet remain.

Whitstable, in Whitstable hundred, in the lathe of St. Augustine, on the æstuary of the Thames, is about six miles from Canterbury, with which city it communicates by a railroad. It may be considered as the port of Canterbury. Hoys convey goods to and from London, and colliers discharge their cargoes here. The inhabitants are engaged in the oyster fishery; in dredging for oysters round a rock called 'the Pudding-pan,' many pieces of Roman pottery have been found. Population in 1831, 1926. What is called Whitstable-street extends into Seasalter parish. A few miles east of Whitstable, on the æstuary of the Thames, is the new watering-place Herne Bay, which contains many good houses and several hotels; but the place has been laid out on

so extensive a scale that it will long have an unfinished appearance. There is a pier or jetty, built on wooden piles, extending three-quarters of a mile over the sand or ooze, which is left dry at low water. A handsome clock-tower stands near the jetty. Steam-boats ply between London and Herne Bay during the season. Herne church, which is about a mile from Herne Bay, has some good portions in the early English and perpendicular style. There is a chapel at Herne Bay.

Divisions for Ecclesiastical and Legal Purposes.—The county was formerly divided between the dioceses of Canterbury and Rochester. The part east of the Medway constituted the diocese and archdeaconry of Canterbury; it was subdivided into the eleven rural deaneries of Bridge, Canterbury, Charing, Dover, Eleham, Limne, Ospringe, Sandwich, Sittingbourne, Sutton, and Westbere, and comprehended, according to Hasted (A.D. 1778) two hundred and eighty-one parishes. The remaining part of the county, west of the Medway, constituted, for the most part, the diocese and archdeaconry of Rochester; it was subdivided into the three rural deanries of Dartford, Malling, and Rochester, and comprehended ninety-eight parishes. The deanery of Shoreham, west of the Medway, comprehending thirty-four parishes, was in the peculiar jurisdiction of the archbishop of Canterbury.

By the late act 6 & 7 Will. IV., c. 77, provision has been made for the alteration of these arrangements. The parishes of Charlton, Lee, Lewisham, Greenwich, Woolwich, Eltham, Plumstead, and St. Nicholas and St. Paul, Deptford, all hitherto in the deanery of Dartford, and diocese of Rochester, and in the neighbourhood of London, are to form part of the diocese of London: the city and deanery of Rochester are to remain part of the diocese of Rochester, to which diocese nearly the whole of Essex and the whole of Hertfordshire are added; the remainder of Kent is to form the diocese of Canterbury. The deancry of Rochester is to form an archdeaconry.

Kent is in the Home circuit, excepting certain parishes near London, namely, Charlton, Lee, Lewisham, Greenwich, Woolwich, Eltham, Plumstead, and St. Nicholas and St. Paul, Deptford, which are in the jurisdiction (in criminal matters) of the Central Criminal Court. The assizes are held at Maidstone, where are the county gaol and the house of correction. For subordinate jurisdictions the county is divided into East Kent and West Kent; the former comprehending the lathes of St. Augustine and Shepway, and the hundreds of Middleton or Milton, Teynham, Faversham, Boughton, Felborough, Wye, Calehill, and Chart and Longbridge, forming the upper or northern division of the lathe of Scray; the latter comprehending the lathes of Sutton-at-Hone and Aylesford, together with the hundreds of Marden, Cranbrook, Barclay, Blackbourne, Tenterden, Rolvenden, Barnfield (East), and Selbrittenden, which form the lower or southern division of the lathe of Scray. The justices of the peace, though by their commission appointed for the whole county, usually confine the exercise of their power to their own division of it, and separate quarter-sessions are held, for East Kent, at Canterbury, and by adjournment at Maidstone a day or two after, for West Kent.

The same two great divisions are, since the county was divided by the Reform Act, used for parliamentary purposes. East Kent returns two members; the election takes place at Canterbury, and the polling stations are Canterbury, Sittingbourne, Ashford, New Romney, and Ramsgate. West Kent also returns two members; the court for their election is held at Maidstone; and the polling stations are Maidstone, Blackheath, Bromley, Gravesend, Tunbridge, and Cranbrook. Two members each are returned for the cities of Canterbury and Rochester, for the Cinque-ports of Dover and Sandwich, and for the boroughs of Greenwich and Maidstone, and one member each for the Cinque-port of Hythe and the borough of Chatham. The total number now returned from the whole county is eighteen. Before the Reform Act it was the same, By that Act New Romney and Queenborough, returning two members each, were disfranchised, and Hythe reduced from two members to one, making a deduction of five members; but the loss was exactly compensated by the division of the county, and the creation of the new boroughs of Greenwich and Chatham.

History and Antiquities.—This county comprehends that part of England which from its proximity to the Continent first obtained distinct historical notice. The name is very antient, probably of Celtic original: its meaning has been inferred, from a comparison with other names which seem to include the same element (Cant-ire, Cant-abri, Cant-æ), to be 'corner' or 'projection,' a designation suitable enough to the position of this and of the other countries or nations mentioned.

Cæsar mentions the district by its name, which he gives in the Latinized form Cantium; he ascribes to the inhabitants civilization much superior to that of the other islanders. It was the part on which his attack was made in his first invasion, and he did not then pass beyond its limits: in his second invasion he passed through it to the assault of other tribes; some sharp encounters took place during his march in this county, and in his absence five of the reguli or petty princes of Cantium made an unsuccessful attempt to storm the fortified intrenchment which protected his fleet, B.C. 54. In the invasion under Aulus Plautius, A.D. 43, and in the subsequent wars with the Romans, there are no historical incidents the locality of which can be identified with Cantium, except the destruction of London by the insurgents under Boadicea. Ptolemy places Λονδίνιον (Londinium) among the towns of the Κάντιοι (Cantii, or people of Cantium); a statement which, if accurate, supposes the district to have exceeded the limits of the present county, whether we place the antient Londinium on the north or south side of the Thames; and which, if we place the original site of London on the north of the river, as it most likely was, supposes that some part of Middlesex must have been included in Cantium.

In the division of the Roman empire which prevailed in its later period Cantium was comprehended in the province of Britannia Prima (one of the four into which the diocese of Britain was divided), except that part of it (if any) which lay north of the Thames, which was in the province of Flavia Cæsariensis. Several important stations were within the limits of the modern county. There were the four harbours of Regulbium, Reculver; Ritupæ, or Ad Portum Ritupis, Richborough near Sandwich; Dubræ, or Ad Portum Dubris, Dover; and Lemanæ, or Ad Portum Lemanis, Lympne or Limme, near Hythe. Roads from these places met at Durovernum, or Canterbury; from whence the military way called Watling Street ran in a direct line to Londinium, London, passing by the way through Durolevum, Newington, or more probably Judde Hill near Ospringe; Durobrivæ or Durobrivis, Rochester; and Vagniacæ, Southfleet near Gravesend. The above places, with the exception of Regulbium, are mentioned in the 'Itinerary of Antoninus,' which also notices Noviomagus, Holwood Hill near the source of the Ravensbourne, which though placed in the Itinerary between Vagniacæ and Londinium, was out of the line of Watling Street. Regulbium is mentioned in the 'Notitia Imperii' and by Richard of Cirencester. Besides these there were other stations, as Madus, mentioned by Richard and noticed in the Peutinger table or map; and Anderida, a harbour mentioned both in the 'Notitia Imperii' and by Richard, but which is more likely to have been on the coast of Sussex. Besides Watling Street, and Stone Street, which runs from Canterbury to Lympne, there were probably several Roman roads in Kent which have not been distinguished by any particular name.

Of these stations and roads there are many remains. Regulbium, now Reculver, defended the northern entrance of the channel between Thanet and the rest of the county. The encroachments of the sea have washed away part of the station. The church of Reculver, which forms a well known sea-mark, occupies the centre of it. The enclosure was a square with the angles rounded off. Parts of the walls on the east, south, and west side yet remain: in their general structure they bear a close resemblance to those of Richborough Castle, but are in a much inferior state of preservation. The town is supposed to have been to the north of the station, on a site now undermined and washed away. Many Roman antiquities of various kinds have been discovered here, and imperial coins are still often found after heavy rains. Richborough Castle, near Sandwich, is the Ritupæ or Ad Portum Ritupis of the Romans. The name of this place is variously spelt. It is called Ad Portum Ritupis in Antoninus; 'Ρουτούπιαι by Ptolemy; Rhutupis by Richard of Cirencester, who terms it a colony; and Ratupis in the Peutinger table. Ritupæ is the presumed nominative of Ritupis, as Dubræ of Dubris. and

Lemanæ of Lemanis. Richborough is one of the noblest Roman remains in the island. It was the usual place of communication with the Continent, and guarded one mouth of the channel which then insulated Thanet. It stands on a small elevation, along the base of which the Stour flows, and about one mile in a direct line from its entrance into Pegwell Bay. The walls form a parallelogram, but the east wall has disappeared and probably fallen into the Stour. The area within the walls is five acres. The walls are flanked by projecting round towers at the angles, and by intermediate round towers. There is a large opening in the west wall, and a narrower one, the Porta Decumana, in the north wall. The foundations of the walls are laid with great care; and the walls were built of blocks of chalk and stone, and faced on both sides with squared blocks of Portland or grit-stone, banded at intervals with double rows of large flat tiles. The walls to the height of six feet are eleven feet three inches thick, above that height they are ten feet eight inches. The top of the wall is everywhere imperfect; its greatest height is twenty-three feet. A quarter of a mile from the south-west angle of the castle are the remains of a Roman circular amphitheatre of about seventy yards diameter. Coins and other antiquities have been dug up here. In the circuit of Dover Castle are the ruins of a pharos or watch-tower, an indubitable relic of the Roman Dubræ. This watch-tower has an octangular base externally, but within it is a square: the height, when Stukeley examined it, was about forty feet, but the upper part is an addition or repair of a later period. The foundations were laid in a bed of clay, though it is built on a chalk rock. The structure is composed of long, thin, irregular bricks, with intermediate courses formed by blocks of hard stalactitical incrustations: it is now in a very dilapidated state. The ruin of an old church adjoining the pharos is not Roman, but Roman bricks have been worked up in it.

At Lymne, or Lympne, near Hythe, are the remains of the Roman fortress Lemanæ, or Ad Portum Lemanis. This fort, now called Stutfall Castle, had an area of about five acres. Stukeley and Leland have much exaggerated it; the walls are imperfect, and have been overthrown in some places by the subsidence of the soil, which here forms a steep hill or cliff on the edge of Romney Marsh. The river Limene or Rother formerly had its course under this hill and formed the harbour. Richard spells the name of this place Lemanus.

At Durovernum (Canterbury) numerous antiquities have been discovered, and until towards the end of the last century three semicircular arches of Roman bricks were standing in different parts. Many Roman bricks have been worked up into the city walls. Richard gives to Durovernum the name Cantiopolis. At Durobrivæ (Rochester) various antiquities have been found, and Roman bricks have been worked up in the ruined walls of the cathedral precinct. The name of this place is said to have been corrupted in the later period of the empire into Roibis (Roibæ), or, in the Peutinger table, Raribis (Raribæ). From Roibis or Roibæ appears to have been formed the Saxon Hrof-Ceastre and the modern Rochester. Bede however derives Hrof-Ceastre from one Hrof, a Saxon chieftain. To Durolevum two positions have been assigned: at Newington there are the remains of entrenchments, and an abundance of Roman pottery has been dug up; on Judde Hill, in the parish of Ospringe, south of the Canterbury road, which agrees better with the distances of the Itinerary, are the remains of a square camp with the corners rounded off. Roman coins and fragments of culinary vessels, intermixed with many parcels of oyster shells, have been found; and in the ruins of Stone Chapel, just on the other side of the road, Roman bricks have been worked up, and in one place a separate piece of a Roman wall has been built in. At Southfleet, the Roman Vagniacæ, a large earthern vessel and a stone tomb containing several funeral antiquities were discovered early in the present century. On Holwood Hill, near Farnborough, on the Hastings road, the antient Noviomagus there are the remains of an immense elliptical encampment, in which Roman bricks and tiles have been turned up by the plough, and Roman coins picked up. Noviomagus, is said by Richard to have been the metropolis of the Bibroci. To the Madus of Richard (perhaps it should be Ad Madum) it is difficult to assign a position which will accord with the distances given by him. The name would lead us to Maidstone, or some post, or ferry, or ford, on the Medway, but the dis[illegible] as they stand will not admit of this Some identify the place with Durobrivæ or Rochester, but the numbers will not agree with this supposition. It may be mentioned here, that the numbers in Richard's Itinerary (Durolevo.. Mado XII. Vagnaca XVIII.), if transposed, would sufficiently well suit the distance of Maidstone from Judde Hill and Southfleet respectively, if we suppose a branch road from the Watling Street at Newington to Maidstone, and another road direct from Maidstone to Watling Street at Southfleet. The remains of an entrenchment at Newenden, the discovery of some Roman coins, and a tradition, mentioned by Camden, that a very antient town and harbour had existed here, have led some to fix on this as the site of Anderida. But the distance from Ad Portum Lemanis in Richard, and the declaration of Gildas, that it was in 'littore oceani ad meridiem,' would lead us to some position on the Sussex coast as the site of that town.

Of the Roman roads, the Watling Street, which nearly coincided with the present road from London to Canterbury, may be traced in several places. Dr. Plot observed traces of it on or near Blackheath. It is still visible on Bexley Heath, and again just beyond Dartford, where the modern road bends to the left towards Gravesend, while the Street pursues a direct course through Southfleet to Rochester. From hence to Canterbury the antient and modern roads coincide, and the traces of the antient one appear to have been, except in a few places, obliterated. The branch of Watling Street which led from Durovernum (Canterbury) to Lemanæ (Lympne), is still conspicuous for some miles. It pursues a straight course between the two places, and is known by the name of Stone Street.

The North Foreland is mentioned by Ptolemy under the name of Κάντιον or Ἀκάντιον ἄκρον, the promontory Cantium or Acantium. The Medway, the Stour, the small stream which enters the sea at Dover, and the Rother, appear to be mentioned in Richard under the respective names of Madus, Sturius, Dubris, and Lemanus. Thanet appears in the pages of Richard under the name of Thanatos, and the channel which insulates it, under that of Wantsuam. Cauna, which appears in Richard's map, is probably Canvey Island on the Essex shore; but its position more nearly resembles that of Sheppey.

In the Saxon invasion Cantium was the scene of many interesting events. The brothers Hengist and Horsa landed in Pegwell Bay, near Ipwines Fleet, now Ebb Fleet, in Thanet, probably about A.D. 446 or 449. Their force consisted of three ships, and perhaps three hundred men; and it is uncertain if their arrival was accidental, or whether they premeditated an incursion for the sake of plunder. One of the island princes, Wyrtgeorn or Gwrtheyrn (popularly Vortigern), engaged them to support him against the invasions of the Scots, whom they repelled. The names of Hengist and Horsa are poetical names (both in the Anglo-Saxon denoting a horse); and their exploits are, if not entirely fabulous, of so doubtful a character as to deserve little credit. Having received a grant of the Isle of Thanet, then insulated by a channel of some width, they received accessions of strength from their countrymen at home, and were soon involved in hostilities with the Britons. Thanet was called by the Britons Ruim or Ruym.

Of the early battles of Hengist and his Jutes with the Britons, the principal were fought in the year 455; the first on the Dereuent (Darent); the second at Epsford or Eglesford (Aylesford) on the Medway, in which battle the British prince Catigern, son of Vortigern, and the Saxon Horsa, fell; and the third at Stonar, near Sandwich. The localities indicate that at the commencement of the struggle the Jutes had advanced some way into the island, and that they were gradually repelled. The antient chronicles distinctly assign the victory in the second and third engagements to the Britons, who were led by Guortemir, popularly called Vortimer, son of Vortigern; after the battle of Stonar, the Jutes fled to their ships, and did not return to England till Vortimer's death, two years after. In A.D. 457, Hengist and his son Eric or Æsc, are said to have defeated the Britons with great slaughter at Creccanford (Crayford), the position of which indicates the advance of the Jutes; yet that advance was probably only for plunder, as the next recorded engagement, eight years after, A.D. 465, was at Wyppedes-fleot in Thanet. In A.D. 473, the Jutes obtained another victory at a place not named. Hengist died some years after (A.D. 488), leaving a reputation out of all proportion to the real extent of his achievements. The ravages of others seem to have been ascribed to him, and his pre-eminence

has probably resulted from his priority in point of time rather than from the wider extent or greater destructiveness of his devastations. Even their priority in point of time is questionable; for it has been supposed that during the decline of the Roman power the east coast, or the Saxon shore, had been to a considerable extent colonized by Saxons. Hengist's dominions never extended beyond Kent, and it may be questioned if he ever took the title of king. His son Æsc did; and was honoured as the real founder of the Kentish dynasty of the Æscingas, or sons of the ash-tree. Kent was called by the Saxons Cantwaraland: Durovernum became Cantwarabyrig or Cantwaraburh, whence Canterbury. In a Latin charter of Ethelbert, Kent is Cantia, and Canterbury Dorobernia.

Æsc was succeeded by Ocha or Octa, and Ermeric, whose genealogy and the period of whose reigns are obscure. Kent passed unnoticed in the more exciting events which occurred in other parts. But Oedilberct (Bede) or Aethelbyrht, or in Latin Ethelbertus, popularly Ethelbert, who succeeded Ermeric, was of a more aspiring disposition than his predecessors. In the year 568, being only sixteen years of age, he claimed the supremacy of the Anglo-Saxon princes, and invading the dominion of Ceawlin, king of Wessex, the most powerful of them, was defeated by that prince and his brother Cutha, or Cutholf, at Wibbandune (perhaps Wimbledon in Surrey). In A.D. 589 or thereabout, Ethelbert obtained the supreme power or dignity of Bretwalda, which he retained till his death A.D. 616. After the conversion of Ethelbert to Christianity, a church was built by Augustin, adjacent to the royal palace, which was the precursor of the present cathedral of Canterbury, which, from the political supremacy of Ethelbert and his earlier conversion, became the ecclesiastical metropolis of England. [ETHELBERT.]

Under Eadbald, son and successor of Ethelbert, the crown of Kent lost the supremacy which the talent or power of Ethelbert had acquired. A succession of obscure princes followed: Erconbert, A.D. 640; Ecgbryht, or Egbert, A.D. 664; Hlothere, or Lothar, A.D. 673,—in the reign of this prince Ethelred, king of Mercia, invaded Kent, put Hlothere to flight, and destroyed Rochester, A.D. 676; Eadric (A.D. 685) had previously reigned for some time in conjunction with Hlothere, with whom he was competitor for the royal power, which he compelled him to divide. In this reign, A.D. 686 and 687, Ceadwalla, king of Wessex, and his brother Mollo, or Wolf, attacked and ravaged Kent with extreme ferocity. Mollo was surprised by the Kentish men, driven into a hut, and burnt with twelve followers. Ceadwalla however established his supremacy over the kingdom of Kent, and held it till his abdication, A.D. 688. Wihtred and Swaebhard or Waebhard, were kings of Kent about A.D. 690 and 693: the former reigned for more than thirty years. He paid a heavy fine to Ina of Wessex, who had invaded Kent, as an expiation for the death of Mollo. Ethelbert, Eadbert, and Alric, brothers, reigned in conjunction under the supremacy of Mercia, A.D. 725. Alric was the survivor of the three, and in him ended the line of the Æscingas.

In A.D. 752, Kent was subject to Mercia, for Kentish men formed part of the army of Ethelbald, the Mercian king, in his war against Cuthred of Wessex. In the following half century Kent appears to have been in an unsettled state, and was perhaps divided between two or more petty princes: among whom Alchmund, Eadmund, or Eanmund, father of Egbert, afterwards king of Wessex, may be numbered. During part, if not the whole of this period, Kent was in subjection to Mercia, having been conquered by Offa, who defeated the Kentish men, A.D. 776, at Ottford. About A.D. 796 or 797, Eadbert, or Ethelbert Pren, king of Kent, was attacked by Cenwulf of Mercia; and having been seized by some of his own subjects 'the Merscwara,' or men of Romney Marsh, was by them cruelly mutilated and delivered up to the Mercians. Cenwulf bestowed the crown of Kent on his brother Cuthred, as subordinate prince; but on his death resumed the direct government of it. Other princes subordinate to Mercia were however soon appointed, of whom Baldred was one. Wessex was now establishing its supremacy over the other Anglo-Saxon kingdoms. Egbert, king of the West Saxons, having defeated the Mercians at Ellandun or Wilton, A.D. 823, dispatched a force into Kent under his son Ethelwulf, the Ealdorman or Alderman Wulfheard, and Alstan, bishop of Sherbourn. Baldred fled at their approach; and Kent passed from under the Mercian supremacy to that of the West Saxons, under which it long remained.

From this time Kent, with which Surrey and Sussex, and probably Essex, were incorporated, became a subordinate part of the West Saxon empire. It commonly formed the appanage of the eldest son, or heir apparent, of the king of Wessex, and when the heir succeeded to the paramount sovereignty he usually resigned the Kentish crown to his heir. Thus Ethelwulf, son of Egbert, was, during his father's reign over Wessex, king of Kent; and when he succeeded to the throne of Wessex, he bestowed Kent successively on his sons Athelstane and Ethelbert; the latter of whom retained the crown when his brother Ethelbald ruled over Wessex, and, on the death of Ethelbald, united Kent and Wessex under one sceptre. It is to be observed that after the death of Athelstan, Ethelwulf united for awhile the direct administration of the sovereignties of Kent and Mercia in his own person; and afterwards reigned in Kent in conjunction with Ethelbert, who was subordinate to him. In a grant, Ethelwulf takes the title of 'Rex Occidentalium Saxonum necnon et Cantuariorum.' During the reign of Ethelwulf in Wessex, and of his sons in Kent, the latter kingdom was repeatedly attacked by the Danes: Canterbury and Rochester were sacked by them. Athelstan, king of Kent, and the alderman Elchere, or Ealhere, however defeated the Danes at Sandwich, and took many of their ships. At a subsequent period the Danes landed in the Isle of Thanet, and vanquished the men of Kent and Surrey.

In the warfare of Alfred the Great with Hastings the Northman, Kent was again the scene of conflict. In the year 893 a fleet of two hundred and fifty vessels arrived on the coast, and the crews having landed in Romney Marsh, and built a fort at Apuldre, now Appledore, on the Rother, marched inland to ravage the country. Hastings himself with eighty vessels arrived in the East Swale, landed at Milton, and threw up a strong intrenchment near Sittingbourne. Alfred marched an army into Kent, and encamped between the two divisions of Hastings, which he thus kept in check: but the Northmen, by a rapid march, passed his army and penetrated into Surrey. Their subsequent hostilities and ravages, though widely spread, do not appear to have touched Kent.

From this time the crown of Kent was never separated from that of Wessex. The 'Juti Cantiani,' Jutes of Kent, are mentioned by an antient chronicler as subdued by Edward the Elder in the very commencement of his reign: they perhaps at first supported the claim of his cousin and competitor Ethelwold, though in a subsequent part of the struggle they supported Edward. In the next reign, that of Athelstan, Kent possessed its separate legislature, which regulated the terms on which the laws of Wessex should be accepted. Traces of the distinct laws and franchises of Kent continued however till long afterwards.

In the reign of Ethelred (A.D. 980, 991) when the Northmen renewed their ravages, Kent was subjected to their fury until they were bought off by Ethelred. In A.D. 993 they appeared with a fleet off Sandwich, which they plundered. In the following year they ravaged Kent and other parts until again bought off by the king. In the year 998 they entered the Medway, took Rochester, and plundered the western part of the county. In A.D. 1006 Sandwich was plundered by Sweyn, king of Denmark, who retired on the approach of Ethelred into the Isle of Thanet; and he soon after received a large sum from Ethelred as the price of his retreat. In A.D. 1008 a large Saxon fleet had its rendezvous at Sandwich, but performed nothing; and the next year the Danes landed in the Isle of Thanet, and being joined by their countrymen from other parts, besieged Canterbury, from the inhabitants of which they extorted a large sum as the price of their retreat. In subsequent years they renewed their ravages in Kent, took Canterbury by treachery, plundered it, and reduced it to ashes. In the short but fierce struggle between Canute and Edmund Ironside, Kent was again the scene of contest. Edmund defeated his rival at Otford, in 1016, and drove him to the Isle of Sheppey.

In the reign of Edward the Confessor Kent was included in the earldom of the famous Godwin, but it does not appear that he took his title from it, but from his more important earldom of Wessex. The earldoms of that day were not mere titles, but conveyed viceregal power over the districts confided to the earl.

At the great battle of Hastings the men of Kent formed the vanguard of the Anglo-Saxon army: it was their privi-

lage to occupy that post. A detachment of the Norman force having landed at Romney just before the battle, were defeated by the townsmen, which led William, when after the battle he marched along the coast, in order to secure the ports which communicated with the Continent, to burn that town and massacre the inhabitants. Having secured Dover Castle after a slight resistance, hung the governor, and burnt the town, he marched toward London by Watling Street; and in his way conciliated the favour, or at least disarmed the resistance, of the men of Kent, by granting them the continuance of their privileges. An unsuccessful attempt was subsequently made, A.D. 1067, by the Kentishmen, aided by the Earl of Boulogne, to surprise Dover Castle. In the reign of William Rufus, Kent was the scene of civil war: Odo, bishop of Bayeux and earl of Kent, raised the county in favour of Robert duke of Normandy. Rochester town and castle were defended on behalf of Odo, to whom the castle belonged, by Eustace earl of Boulogne, and the besieged did not capitulate till after a siege of many weeks. King John, when threatened with an invasion by Philippe II. Auguste of France, encamped with an army of 60,000 men on Barham Downs; but his courage failed him, and he made his memorable submission and surrender of his crown to Pandulphus, the Pope's Legate, at Dover. In the subsequent troubles, A.D. 1215, John collected an army of mercenaries at Dover, and marched inland; but William de Albini bravely defended Rochester Castle for three months against him, at which he was so enraged that on the surrender of the castle he ordered all the common soldiers, except the cross-bowmen, to be hung. In A.D. 1216, Louis, dauphin of France, landed in the Isle of Thanet, near Sandwich, in order to assist the barons, and took the castle of Rochester after a short siege; but after his retreat and the death of John, it again submitted to the crown. The rest of Kent submitted for a time to Louis, except Dover Castle, which was all along defended for the king against the Dauphin and the barons by Hubert de Burgh. In the troubles of the succeeding reign Rochester Castle was defended for the king against Simon de Montfort, who besieged it in vain.

It was in Kent that the rebellion of Wat Tyler broke out. The commons in this county and in Essex rose in a body, A.D. 1381. They attacked the archbishop of Canterbury's house at Maidstone, and released John Balle, a priest, who had been imprisoned for teaching doctrines like those of Wickliffe. The issue of the rebellion is well known. In the reign of Henry VI. the insurrection of Jack Cade broke out in Kent, A.D. 1450. [CADE.]

At the outbreak of the war of the Roses, A.D. 1451, Richard duke of York encamped near Dartford, where he fortified himself. The king, Henry VI., encamped on Blackheath. Some years afterwards, A.D. 1460, the navy which the duke of Somerset had collected at Sandwich was surprised and captured by an expedition from Calais, then in the power of the Yorkists. The earl of Warwick soon after landed at Sandwich and marched to London, being joined on his way by nearly 40,000 men. The bastard of Falconbridge, a Lancastrian, after his unsuccessful attempt on London, A.D. 1471, encamped on Blackheath, whence he slowly retreated through Kent to Sandwich, where he had a fleet: he submitted however to Edward IV., and surrendered his fleet and the town.

In the reign of Queen Mary, Kent was the scene of rebellion under Sir Thomas Wyatt, A.D. 1554. In the civil war of Charles I. and the Parliament, a severe battle was fought at Maidstone, A.D. 1648, in which the Parliamentarians, under Fairfax, obtained a complete victory.

In the reign of Elizabeth the river Medway appears to have formed the only harbour for the royal navy, then in its infancy. The dock at Chatham was built by that queen; and she erected Upnor Castle, on the opposite side of the Medway, to defend the passage of the river. In the reign of Charles II., A.D. 1667, a detachment from the Dutch fleet under De Ruyter sailed up the Medway as far as Upnor Castle. [CHATHAM.]

Of ancient castellated edifices, not already noticed or referred to, the most remarkable are Leeds, Hever, Chelham, Allington and Westerhanger castles, to which may be added the castellated mansions of Penshurst and Knowle. Leeds Castle is to the right of the road from Maidstone to Ashford, four or five miles from Maidstone. It is surrounded by a broad moat: the entrance is by a stone bridge of two pointed arches, and through a deep gateway in good preservation. Another gateway, which defended the entrance of the bridge, is in ruins. Part of the building has been modernized: the foundations of the more antient part, which formed the keep, rise immediately from the water, and are very strong. Leeds Castle was the residence occasionally of Richard II. and Henry IV. Hever Castle, on the Eden, one of the upper waters of the Medway, was erected in the time of Edward III., and possesses some historical interest as the residence of the Boleyn family. Here Henry VIII. used to visit Ann Boleyn in the days of their courtship. The castle is surrounded by a moat: the entrance gateway is flanked by round towers; the inner buildings form a quadrangle enclosing a court. Chilham Castle, about midway between Canterbury and Ashford, occupies a site on which there was probably a Roman building. After the Conquest a Norman castle was built here, of which the keep is the only part in good preservation. It is an irregular octagon of three stories, with walls ten or twelve feet thick, built of flint, chalk, and stone intermingled, faced with squared stone, and now mantled with ivy. The interior has been much altered and damaged: the view from the platform is very fine. The remains of Allington Castle, on the left bank of the Medway just below Maidstone, are occupied as two tenements. Allington was the seat of Sir Thomas Wyatt, an accomplished scholar of the time of Henry VIII., and of his son Sir Thomas, who suffered for treason against Queen Mary. Of Westerhanger, or Westonhanger, near Hythe, the principal remains are the outer walls, with the towers of the north and east sides, and a small chapel. Penshurst Castle is a very extensive pile. It is one of those castellated dwellings that immediately succeeded the baronial castles of a more troubled period. The principal buildings form a quadrangle enclosing a spacious court, and comprehending a hall, chapel, and other apartments. It derives its chief interest from having been the residence of the Sydney family. Knowle, or Knole, near Sevenoaks, the residence of the Sackvilles, dukes of Dorset, is another extensive and magnificent mansion: the principal buildings form a spacious quadrangle, and are in the castellated style. The greater part is of the fifteenth century, but some portions of it are yet older. There are earthworks, remains of castles, at Cowling, near the mouth of the Thames; at Thurnham, on the brow of the chalk hills near Maidstone, and one or two other places. Sandown, Sandgate, and Walmer Castles, all on the coast, hold a middle place between antient and modern fortifications. They are coeval with Deal Castle, and are of the time of Henry VIII.

Of monastic remains the principal are St. Augustine's Abbey [CANTERBURY], Aylesford Priory [AYLESFORD], and St. Radigund's Abbey, near Dover, which was founded about A.D. 1191, for Premonstratensian canons: its yearly revenue at the dissolution was 142*l.* 8*s.* 9*d.* gross, or 98*l.* 9*s.* 2½*d.* clear. The walls of the outbuildings, gardens, &c., cover a considerable extent of ground, and the whole appears to have been surrounded by a semicircular rampart and ditch. The walls of the entrance gateway are nearly entire; the north and west sides of the chapel, and part of the dwelling, now patched up as a farm-house, are also standing. The walls are generally covered with ivy. There are considerable remains of the Benedictine priory at Dover, including the gateway and refectory, both nearly entire. The abbeys of Faversham and Malling, and the priories of Tunbridge and Folkestone, have been already noticed. Of Boxley Abbey, near Maidstone, there are few remains; and the abbey buildings at West Langdon, not far from Dover, have been new fronted with brick and much altered. There are some remains of the priories of Bilsington, on the edge of Romney Marsh, and of Monks Horton, near Stone Street causeway, of which last the western entrance to the church is a small but beautiful ruin of late Norman architecture, with insertions of windows and doors of perpendicular character. The chapel of St. Nicholas's Hospital at Harbledown, near Canterbury, is partly of Norman and partly of later architecture.

Of the churches of the county the most worthy of note are its two cathedrals [CANTERBURY; ROCHESTER]. For antiquity Barfreston, or Barston Church, between Canterbury and Dover, but not on the high road, is most deserving of notice. This has been considered to be of Anglo-Saxon architecture, but is more probably Norman. It consists of a nave and chancel, having a joint length of 43 feet 4 inches; the width of the nave, 16 feet 6 inches; of the chancel, 13

feet 6 inches, interior dimensions. The nave and chancel communicate by an arch rising from wreathed columns and richly sculptured. There have been some insertions, but on the whole the church is much in its original state. Several other churches, including St. Mary's at Dover, are chiefly valuable for their Norman features; but the predominant character in the churches of the county is the early English.

Statistics.

Population.—The inhabitants of Kent are principally engaged in agricultural pursuits. The government establishments at Chatham, Deptford, and Woolwich give employment to numerous artisans and labourers; but out of 155,655 males, twenty years of age and upwards, living at the enumeration of 1831, only 476 were returned as employed in manufactures or in making manufacturing machinery. Of these 164 were employed in calico-printing at Crayford and Bexley, 88 in weaving bagging at Maidstone, and the remaining 224 were employed as millwrights and in chemical works at Deptford and Greenwich, in the gunpowder-mills at Dartford, and in the making of Tonbridge-ware. Compared with the other counties of England the proportion of persons engaged in agriculture in Kent has been increasing. Under this aspect it stood thirty-third on the list in 1811, it was the twenty-eighth in 1821, and in 1831 it ranked the twenty-fifth. The actual proportions at each of the three periods here mentioned were—

	1811.	1821.	1831.
Families employed in Agriculture . . .	35·5	35·9	32·6
" Trade, Handicraft, &c. .	36·7	35·1	30·3
Other classes	27·8	29·	37·1
	100·	100·	100·

The population of Kent at each of the four enumerations made during the present century was—

	Males.	Females.	Total.	Increase per cent.
1801	151,374	156,250	307,624	..
1811	183,500	189,595	373,095	21·28
1821	209,833	216,183	426,016	14·18
1831	234,572	244,583	479,155	12·47

showing an increase between the first and last periods of 171,531, or 55⅘ per cent., which is very nearly equal to the whole rate of increase in England and Wales during that interval.

The following table gives a summary of the population of every hundred, &c., in the county, as found at the census of 1831:—

Summary of the County of Kent.

LATHES, CITIES, OR BOROUGHS.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.
St. Augustine (Lathe) . .	13,254	14,999	122	619	5,612	4,086	5,301	36,395	38,519	74,914	17,654

Militia under training . .	..	..	..	..	..	..	..	585	..	585	..
Totals . . .	82,144	97,142	842	3,818	31,667	29,419	36,056	234,572	244,583	479,155	155,655

County Expenses, Crime, &c.—The sums expended for relief of the poor at each of the four dates when the census was taken were—

	£.		s.	d.	
1801 . .	206,508,	being	13	5	for each inhabitant.
1811 . .	317,990	"	17	0	"
1821 . .	370,711	"	17	4	"
1831 . .	345,512	"	14	5	"

The sum expended for the same purpose in the year ending 25th March, 1837, was 185,503*l.*; and assuming that the population has increased since 1831 at the same rate of progression as in the ten preceding years, this sum gives an average of 6*s.* 10½*d.* for each inhabitant. These averages are all above the general averages for the whole of England and Wales.

The sum raised in Kent for poor-rate, county-rate, and other local purposes, in the year ending 25th March, 1838, was 433,274*l.* 16*s.*, and was levied upon various descriptions of property as under:—

On land . .	£275,810	11*s.*
Dwelling-houses .	140,513	8
Mills, factories, &c. .	12,510	17
Manorial profits, navigation, &c.	4,440	0
	433,274	16

The expenditure in the same year was—

For the relief of the poor . .	£369,587	13
In suits of law, removal of paupers, &c.	16,011	5
For other purposes . .	64,752	16
	450,351	14

The returns made up during subsequent years do not specify the proportions in which different descriptions of property were assessed. In the four years ending with 25th March, 1837, there were raised for local purposes—

1834 . . .	£418,785	13*s.*
1835 . . .	370,718	19
1836 . . .	313,669	7
1837 . . .	215,499	0

The expenditure for each of these years was as follows:—

	1834. £.	s.	1835. £.	s.	1836. £.	s.	1837. £.
For the relief of the poor .	343,878	9	297,098	6	247,929	12	185,503
In suits of law, removals, &c.	15,339	11	12,371	3	9,383	16	6 206
Payments towards the county-rate . .	65,439	14	24,790	2	22,933	12	..
For all other purposes			47,742	18	40,127	1	23,790
Total money expended	£424,648	14	382,002	9	320,374	1	215,499

The saving effected on the sum expended for the relief of the poor in 1837, as compared with the expenditure of

1834, was therefore 46 per cent.; while the saving on the entire expenditure, comparing those two years, was 47 per cent.

The number of turnpike-roads' trusts in Kent, ascertained in 1835 under the Act 3 and 4 William IV., chap. 80, was 50; the number of miles of road under their charge was 586. The annual income arising from tolls and parish compositions in lieu of statute duty was, in 1835, 73,674*l.* 1*s* 6*d.*, and the annual expenditure in the same year was 72,801*l.* 18*s.* 7*d.*, as follows:—

	£.	s.	d.
Manual labour	15,112	9	5
Team labour and carriage of materials	10,767	4	0
Materials for surface repairs	8,144	14	8
Land purchased	998	0	3
Tradesmen's bills, law charges, &c.	4,677	8	4
Salaries of treasurer, clerk, and surveyors	3,708	7	10
Improvements	5,743	5	2
Interest of debt	10,321	6	7
Towards redemption of the debt	11,089	10	0
Incidental expenses	2,239	12	4

The county expenditure in 1834, exclusive of that made for the relief of the poor, was 16,692*l.* 15*s.* 6*d.*, and was disbursed as follows:—

	£.	s.	d.
Bridges, building, repairs, &c.	1,538	0	6
Gaols, houses of correction, and maintaining prisoners	5,651	0	11
Shire-halls and courts of justice, building, repairing, &c.	260	13	10
Lunatic asylum	1,105	17	4
Prosecutions	3,562	14	8
Clerk of the peace	1,102	8	8
Conveyance of prisoners before trial	1,475	11	1
Apprehending and conveying vagrants		15	3
Constables, high and special	226	18	10
Coroner	419	6	0
Miscellaneous	1,319	8	5

The number of persons charged with criminal offences within the county in each of the three septennial periods ending with 1819, 1826, and 1833, were 2741, 3800, and 4640, being an average of 391 annually in the first period, of 543 in the second period, and of 663 in the third period. The numbers accused in subsequent years were—

1834	775
1835	894
1836	872
1837	896

Of the number accused in 1837 there were—

	Males.	Females.	Total.
For offences against the person	50	3	53
„ „ against property, with violence	48	5	53
„ „ „ without violence	623	131	754
„ forgery and offences against the currency	21	5	26
„ other offences, not included above	8	2	10
	750	146	896

The number of persons against whom bills were not found by the grand jury, and who were acquitted on trial, was 246; of the remaining 650 who were convicted, 481 were for simple thefts, and 25 for common assaults. There were 9 persons sentenced to death; of these 8 had their punishment commuted to transportation for life, and the other to transportation for seven years. Of the remaining convicts there were transported—

The number of electors qualified to vote for the county members in Kent at the registration of 1837 was, for the eastern division 7293, and for the western division 8132, being about 1 in 30 of the whole population, and about 1 in 10 of the male population 20 years of age and upwards, as taken in 1831.

There are 20 savings' banks in Kent. The number of depositors in these, and the amount of their deposits as they stood on the 20th of November in each of the last five years, were as follows:—

	1833.	1834.	1835.	1836.	1837.
Number of depositors	18,188	19,312	20,010	21,326	22,149
Amount of deposits	£531,018	£566,017	£582,056	£613,804	£629,083

The deposits of the last two years were divided in the following classes:—

		1836. Depositors.	1836. Deposits.	1837. Depositors.	1837. Deposits.
Not exceeding	£20	11,836	£82,248	12,506	£86,194

		21,326	613,804	22,149	629,083

Education.—The following summary is taken from returns made to the House of Commons in the session of 1835:—

	Schools	Scholars.	Total.
Infant schools	207		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		1,325	
Females		1,711	
Sex not specified		1,479	
			4,515
Daily schools	1488		
Number of children at such schools; ages from 4 to 14 years:—			
Males		24,241	
Females		18,496	
Sex not specified		6,469	
			49,206
Schools	1695		
Total of children under daily instruction			53,721
Sunday schools	479		
Number of children at such schools; ages from 4 to 15 years:—			
Males		15,791	
Females		15,556	
Sex not specified		6,176	
			37,523

Assuming that the population between the ages of 2 and 15 has increased in the same proportion with the whole population since 1821, when the relative population at different ages was last taken, and likewise assuming that the whole population has increased since 1831 in the same ratio as it did in the ten years preceding that date, we find by approximation that there were 127,096 children between the ages of 2 and 15 years in Kent in 1834, when these returns were obtained. Thirty-one Sunday-schools are returned from places where no other school existed, and the children

taught in these (1005 in number) cannot be supposed to have attended any other school. At all other places Sunday-school children are able to resort to other schools also, and there can be no doubt that many do so resort; but in what number or proportion duplicate entry is thus occasioned in the Parliamentary Returns there are no means of ascertaining. · Ninety-two schools, containing 7209 children are returned from various places as being both daily and Sunday-schools, and duplicate entry is known to have been thus far created. Making due allowance for this circumstance, it may perhaps be fairly concluded that at the time the inquiry was made little more than three-fifths of the children between the ages of 2 and 15 were receiving instruction of any kind in schools within the county.

Maintenance of Schools.

No school in Kent appears to be confined to the children of parents belonging to the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists, together with schools for the children of Roman Catholic parents.

Lending-libraries of books are attached to 53 schools in the county of Kent.

KENT, WILLIAM, an artist of moderate ability as a painter and sculptor, nevertheless one of considerable ability and influence as an architect and landscape-gardener, was born in Yorkshire, in 1684. Both his parentage and education were humble, and he was apprenticed to a coach-painter. Conceiving however that he had abilities which ought to elevate him above that grade, he attempted to establish himself as a portrait and historical painter, and so far attracted notice that some gentlemen raised a contribution for the purpose of enabling him to go and study in Italy. Thither he accordingly proceeded in 1710, and remained there several years, till he had the extreme good fortune to become acquainted there with the earl of Burlington in 1716. The noble patron not only brought home his protégé, and exerted all his influence and authority in matters of taste to recommend him to others, but took him under his own roof, where he remained till his death, April 12, 1748. How far Kent assisted his patron in his designs, or the latter assisted him, is doubtful; but it is certain that he soon discovered greater capacity for architecture than he had done for painting: and if it be true that the designs for Holkham, the seat of the earl of Leicester, in Norfolk, emanated principally, if not entirely, from him, that single edifice alone proves him to have possessed very superior talent and taste as an architect, it being a chef-d'œuvre in plan, and possessing many graces and beauties of design. As architect and landscape-gardener he was in his proper sphere, and followed both pursuits with the true spirit of an artist. In landscape-gardening, in fact, he forms an epoch, and may justly be considered as the father of the English style of gardening; for, as Walpole, who has not been niggard of praise towards him, observes, he was 'painter enough to taste the charms of landscape, bold and opinionative enough to dare and to dictate, and born with a genius to strike out a great system from the twilight of imperfect essays.' Shakspeare's monument in Westminster Abbey will preserve his name as a sculptor, without at all adding to his reputation. It is therefore fortunate for it that it will bear such retrenchment without injury to its vital part.

KENT, JAMES, a distinguished and deservedly popular composer of English church music, was born at Winchester, in 1700, and at an early age placed as a chorister in the cathedral of that city, but soon removed to London, and admitted as one of the Children of the Chapel Royal, under the celebrated Dr. Croft, then Master of the Children. After completing his education, he was chosen organist of Finden, in Northamptonshire, and subsequently was appointed organist of Trinity College, Cambridge, whence he removed, in 1737, upon being elected to fill the same situation in the cathedral of his native place, an office which he resigned in favour of his pupil, Mr. Fussell, in 1774. He died, deeply regretted, in 1776.

Mr. Kent was very serviceable to Dr. Boyce while the latter was preparing his magnificent work, the *Collection of Cathedral Music*, and his assistance is duly acknowledged by that learned editor. In 1773 he published his now well-known volume of *Twelve Anthems*, among which are, 'Hear my Prayer,' 'When the Son of Man,' 'My Song shall be of Mercy,' and others familiar to and the delight of the congregations of our cathedrals. Upon presenting a copy of this work to Trinity College, the Master and Fellows voted him a valuable piece of plate. After his decease, a *Morning and Evening Service, and Eight Anthems*, composed by him for the Winchester choir, were collected and printed by Mr. Corfe, of Salisbury; but the probability is that the author never intended them for publication, for only the service and one of the anthems admit of comparison with the productions he himself gave to the world.

'Mr. Kent was remarkably mild in his disposition, amiable in his manners, exemplary in his conduct, and conscientiously diligent in the discharge of his duties. His performance on the organ was solemn and impressive, and he was, by competent judges, considered as one of the best musicians of the age in which he lived.' (*Harmonicon.*)

KENT'S HOLE, a cavern near Torquay, which has yielded a great quantity of bones, very similar, as to the species of animals to which they belong, and the condition in which they are preserved, to the bones in Kirkdale Cave. The same explanation of the phenomena probably applies to both cases. [KIRKDALE.]

KENTUCKY, one of the republics constituting the United States of North America, is situated between 36° 30′ and 39° 8′ N. lat., and between 82° and 89° 30′ W. long. Its greatest length is 380 miles, and its mean width 99 miles. The area is stated at 37,680 square miles. Its boundary-lines are formed on three sides by rivers. The Mississippi on the west divides it from the State of Missouri for 42 miles. The Ohio runs along its northern side, in a winding course of 583 miles, separating it from the states of Illinois, Indiana, and Ohio. The Big Sandy River constitutes the boundary between Kentucky and Virginia for 70 miles, but the remainder of the boundary-line between these two states is formed by one of the ridges of the Alleghany Range, called the Cumberland Mountains. The boundary-line between Kentucky and Tennessee, which is to the south, is formed by two straight lines, the eastern running from the Cumberland Mountains eastward to the Tennessee River for 242 miles, on the parallel of 36° 35′ N. lat., and the western between the last-named river and the Mississippi for 84 miles, on the parallel of 36° 30′. Both lines are united by the river Tennessee, whose course constitutes the boundary-line for 12 miles.

Surface and Soil.—The south-eastern portion of Kentucky, which is less than one-tenth of the whole state, is covered with ridges of mountains and high hills, the slopes of which are rather steep, and which contain between them narrow, deep, and gloomy valleys. The whole of this region is well wooded, especially the lower parts of the hills and the vales. None of the summits of these mountains appear to attain the height of 3000 feet above the sea, and their mean elevation probably does not exceed 2000 feet. The highest ranges are the Cumberland Mountains along the boundary-line of Virginia, and the Laurel Mountains, which run parallel to the Cumberland Mountains, and join them between the upper branches of the Kentucky and Cumberland rivers. To the north and west of the hilly region lies what may be called the upland region, which extends from the Big Sandy River, on the boundary of Virginia, to about 86° W. long., and comprehends more than half of the whole area of the state. Its surface is undulating, with gentle ascents and descents, but it is intersected by numerous

deep cuts, which are from 100 to 300 feet below the surface of the plain, and in which the rivers run. The plains belonging to these rivers are narrow. Though this upland region is sparingly provided with spring-water, its soil is of the first quality, and as fertile as any part of the United States. The western portion of the state is divided between the Barrens and a country which is partially hilly. The Barrens in their natural state are generally destitute of trees, and resemble the prairies or savannas which occur north of the Ohio River; but the level surface is diversified by a considerable number of gently rising hills, called *oak knobs*, on account of the trees which cover them. Though this tract does not deserve the name which it bears, it is of inferior fertility when compared with the adjacent countries. The Barrens occupy chiefly the tract between the Green River and Cumberland River, on the borders of Tennessee. On the north and west the Barrens are surrounded by a more broken and hilly country, which gradually passes to the low flats which skirt the Ohio and Mississippi rivers. This tract is superior to the Barrens in fertility, but cannot be compared with the upland region.

Rivers.—Along the northern boundary runs the Ohio, which receives all the larger rivers that drain Kentucky. The most eastern is the Big Sandy River, which rises in Virginia on the western range of the Appalachian system, called the Great Flat-top Mountains, and traverses that state in a north-west direction; where it approaches the boundary-line, it turns nearly due north, and continues in that direction to its very mouth. Its course is stated to be nearly 200 miles, but it is not navigable to a great distance from its mouth, owing to some falls which occur where it issues from the mountain-region. The Licking River rises in Kentucky, and flows, with many windings, in a north-northwestern direction for nearly 200 miles. Though it swells in winter and spring to a considerable height, it has but little water in the other seasons; the limestone rocks through which it passes absorb the water which it brings down from the mountains. The different branches of the Kentucky River rise in the Laurel Mountains and form by their union a considerable stream, which first flows north-west, then west, and at last nearly due north. Its course is about 280 miles, and though it is very rapid, it may be navigated by small boats for 180 miles from its mouth at the time of high-water, but at other times not higher up than Frankfort. Green River rises in the western districts of the upland region and flows for the greater part of its course westward, then declines to the north-west, and finally to the north, joining the Ohio about 50 miles above the mouth of the Cumberland River. Its course is 280 miles, and it is navigable for small river-barges to a great distance, but the navigation is interrupted by falls, about 50 miles from its mouth. Cumberland River rises in the valley between the Cumberland Mountains and the Laurel Mountains, where it is called Clove River; it traverses both the mountain and upland region generally in a western direction, but on approaching the Barrens it turns southward, and enters Tennessee, where it makes a large bend to the southward, and then re-enters Kentucky with a north-western course, continuing in that direction to its mouth, which is ten miles above that of Tennessee River. It is above 500 miles in length, and as its current is comparatively gentle, it offers an easy navigation for sloops as far up as Nashville in Tennessee, and it is stated to be navigable for river-boats 300 miles farther up. The Tennessee River flows only about 70 miles through Kentucky, and properly belongs to Tennessee. [TENNESSEE.]

Climate.—The mean annual temperature seems to be about 55°, and consequently 5° higher than that of London, but the differences in the extremes of heat and cold are much greater. The winters are long and severe: they begin about Christmas, and last three months. The thermometer annually descends as low as 25°, and has been known to sink as low as 14° of Fahr. Snow falls every winter, but not in great quantities. In summer the heat is sometimes very great, and the thermometer rises to 94° and 95°. In spring and autumn south-west winds prevail, and the weather is delightful. The north-west wind produces great cold in winter, but it seldom continues many days. Rain falls abundantly in winter and spring, but in the other seasons the weather is rather dry and constant. Some slight shocks of earthquakes have occurred.

Productions.—The cerealia which are most extensively cultivated are Indian corn, wheat, rye, and oats, and the two last-mentioned kinds of grain are said to thrive better than in the states on the shores of the Atlantic. Rye is commonly used for the distilling of whiskey. In the south-western districts, near and on the Tennessee, Cumberland, and Mississippi rivers, cotton is raised in abundance; and the tobacco which is grown in these districts and the rich lands farther east supplies a considerable article of exportation. Hemp and flax are generally cultivated. The principal fruit-trees are apples and peaches; from the former cider is made, and from the latter peach-brandy, of which there is a great consumption. Cattle are numerous, and great flocks of sheep pasture on the Barrens; the breed of sheep has been improved by crossing them with merinos.

As the greatest part of the country is covered with forests, wild animals are still numerous, as deer, panthers, bears, wolves, foxes, and hares, but the buffalo and the elk have disappeared. Beavers and otters are still found in the rivers. Among the wild birds the turkey is still abundant; it weighs from 10 to 25 pounds. Bees are common in the woods, and make their nests in hollow trees.

The forests contain many timber-trees. Those of the mountains and upland region consist of liriodendron, elm, oak, hickory, black-walnut, cherry, and others; those of the Barrens are chiefly oak, chesnut, and elm.

Bituminous coal and iron abound in the north-western district, and iron also occurs in the districts lying farther westward; but both are of inferior quality. Salt seems to be generally diffused through the country: the salt-springs are numerous, and many of them have been turned to advantage. Saltpetre exists in most of the caverns which occur in the limestone-rock of the upland region, and is most abundant in the Great Cave near Crooked Creek, the length of which is stated to be not less than ten miles.

Inhabitants.—The native tribes, which rendered the settlement of this state so difficult and dangerous seventy years ago, have entirely disappeared, and the population now consists entirely of whites and negroes, and a mixture of the two. The free population comprehended, according to the census of 1830, 523,490 individuals, and the number of slaves was 165,350, making a total of 688,840 souls. The inhabitants are almost exclusively employed in agricultural pursuits, the number of persons engaged in manufactures being comparatively very small. The most important manufacture is the construction of vessels, small and large, for the navigation of the Ohio and Mississippi.

Political Divisions and Towns. Kentucky is divided into 83 counties, but as the country has only been settled for about 70 years, it does not contain any large towns. Frankfort, the capital, is built on the right banks of the Kentucky River where it ceases to be navigable for large vessels. It contains about 2000 inhabitants. Many vessels of small size are built here. Lexington, which was formerly the capital, contained (in 1830) above 6000 inhabitants, and some manufactures of cotton, hemp, and paper. Transylvania University, at Lexington, is the most extensive literary institution in the United States west of the Appalachian Mountains. It was founded in 1798, and reorganised in 1818. A well-attended school of medicine and a school of law are connected with this university. Louisville, on the banks of the Ohio, is situated near the great rapids of that river. As these rapids cannot be passed at low water, and even at high water are dangerous, a canal has been cut along the bank, which begins above the rapids at Beargrass-creek, and terminates below them at Shippingport. This canal is 10 miles long. Louisville, which is the port of the upland region and the place from which the produce of the country is sent down the Ohio and Mississippi, contains above 10,000 inhabitants, and has some extensive distilleries of whiskey and manufactures of cordage and bagging. On the Ohio there is also Bardstown, with 1200 inhabitants; it is the seat of a Catholic bishop and a Roman Catholic college. Maysville, which has 2000 inhabitants and a considerable trade with the neighbouring states, is also on the Ohio. Besides the literary institutions already mentioned, the Methodists and Baptists have each a college, and the Presbyterians have two.

Commerce.—The articles of commerce consist of different kinds of grain, tobacco, hemp, live cattle, whiskey, and peach brandy. The greatest part is sent down the Ohio and Mississippi to New Orleans, between which place and Louisville steam-boats from 200 to 300 tons burthen and upwards are constantly plying. Since the introduction of steam-

boat navigation, the commerce of Kentucky has greatly increased.

History.—It is probable that this part of America once was the seat of a nation which had made some progress in civilization. We may come to this conclusion from observing the extensive fortifications which occur in several places, but especially on the banks of the Ohio, opposite Scioto River, and are now overgrown with high forest-trees. The first Europeans arrived in Kentucky in 1767, and the first settlement was formed in 1775, though Daniel Boone is said to have settled in Kentucky some years earlier. It was then a part of Virginia, but the population having increased rapidly, Virginia consented to a separation, and in 1792, only seventeen years after the first settlement, Kentucky became one of the United States. Its constitution was settled in 1799. The legislative body consists of a senate and house of representatives. The representatives are chosen annually by all the free male citizens (negroes, mulattoes, and Indians being excepted) of 21 years of age, who have been two years resident in the state. The number of representatives may vary between 58 and 100, which latter is now the number. The senate now consists of thirty-eight members, who are elected for four years, one-fourth of the number being chosen annually. The executive power is vested in the governor, who is elected for four years by all the citizens entitled to the suffrages. Kentucky sends two members to the senate, and twelve members to the house of representatives at Washington.

(Darby's *View of the United States;* and Warden's *Account of the United States.*)

KENYON, LLOYD, LORD, the second son of Lloyd Kenyon, Esq., by Jane, daughter of Robert Eddowes of Eagle Hall in Cheshire, was born at Greddington in Flintshire, on the 5th of October, 1732. He was descended from an antient family in Lancashire, which had migrated into North Wales at the commencement of the last century. His father lived independently as a country gentleman, and belonged to the commission of the peace for his county. The education of the future chief-justice was, from the straightened means of the parent, very defective. He was sent early to the grammar-school at Ruthin, but was taken away before he had time to do more than acquire a little Latin. At the age of fourteen he was articled to Mr. Tomlinson, an attorney in large practice at Nantwich in Cheshire, with whom he remained for seven years, during which time his diligence and shrewdness procured him so much of his master's favour that he expected at the end of his clerkship to be taken into partnership. In this expectation he was however disappointed, and thereupon determined upon being called to the bar. In 1754 he took chambers at the Temple, and became a member of Lincoln's Inn. While a student he devoted himself with great earnestness to the law, and to the law only; and in doing this he made smaller sacrifices than most people. He had neither a literary taste nor a love for pleasure; and his pecuniary resources were but scanty. Mr. Kenyon was called to the bar in Hilary Term, 1761, but in consequence of the want of a professional connexion, and being of a character too honourable and independent to stoop to little artifices, many years elapsed before he obtained business. Still he laboured patiently and unceasingly, frequenting the courts both of common law and equity, but more especially the latter, and attending both circuit and sessions. His attainments in all departments appear to have been not only considerable, but exact, and he acquired by degrees the reputation of being a sound lawyer, and a neat and safe equity draftsman and conveyancer. It is stated, that having by some suggestions, as amicus curiæ, attracted the notice of Mr. Thurlow, the then attorney-general, he had the offer made to him of sharing with Mr. Hargrave in the toil and profit of assisting him. In 1773, when he had been twelve years in the profession, he married Mary, third daughter of George Kenyon of Peele in Lancashire. He now began to rise into notice. In 1779 he was retained as one of the counsel for Lord Pigot in the state-prosecution of Shelton and others for depriving him of his government; and afterwards in the same year as leading counsel for Lord George Gordon. In April, 1782, on the accession of the Fox and Rockingham administration, he was appointed attorney-general. While holding this situation his conduct evinced that official intrigue and partisanship were not at all suited to his character. On the death of the marquis of Rockingham he retained his office with Pitt as chancellor of the exchequer, and went out with the Shelburne administration in the spring of the year following. In December he was reappointed attorney-general, having through all the ministerial changes of the day asserted his independence. To the character of an orator he had no pretension, being a man of little imagination, and expressing himself not only without elegance, but occasionally with vulgarity. He was no scholar, and yet he would insert Latin words and phrases without point or taste in his discourse.

In 1784 he was raised to the office of master of the rolls, and created a baronet; and in May, 1788, he was gazetted Lord Kenyon, Baron Greddington, and succeeded Lord Mansfield as chief-justice of the King's Bench. His appointment to this important and dignified situation was at the time unpopular with the profession generally. To the opinion of his brother judges he gave a reception not only of neglect, but almost of contempt; and whenever they ventured to differ from him (which only took place some half dozen times in fourteen years), he exhibited the same feelings which another person would do upon receiving a personal affront. To the barristers, both leaders and juniors, he was equally ungracious; and whenever anything escaped them not in accordance with his sentiments, he castigated them in terms neither measured nor in character with the situation which he filled. To some leading men he would take a personal dislike, and allow no opportunity for mortifying them to escape him; Mr. Law, afterwards Lord Ellenborough, was one of them.

With the press Lord Kenyon was in high favour; for he struck sternly and with indignation at those offenders who are the peculiar objects of popular dislike. But while doing so he frequently gave too easy credit to accusation, and allowed himself to punish often with a severity not sufficiently tempered. As an instance of this we may mention the case of Mr. Lawless, a solicitor, against whom some serious charges were brought. Before the case was adjudicated, Lord Kenyon ordered Mr. Lawless to be suspended from practising until his case was disposed of. In vain did he tell him that he had eighty cases in his office, and that he should be ruined. The charges against Mr. Lawless were found to be wholly without foundation; but the blow was struck, he sunk under the unmerited disgrace, and died of a broken heart. The vices of the wealthy met with no favour from him. In actions for criminal conversation, likewise, he directed juries (over whom no judge had greater power) to give damages of very large amount, and this even in cases where the collusion of the parties or the vicious conduct of the husband ought to have made nominal damages more than sufficient. So strongly did the judge feel with regard to this crime, that he is reported thus to have expressed himself:—'There was a time in the history of this country when the laws of the Puritans, which were mixed with a great deal of virtue, if I mistake not, subjected this offence to the punishment of death. I do not look forward to a punishment so severe; but I wish some personal punishment were attached to those who inflict so dreadful and incurable a wound on the peace of private families.' Gamblers met with similar treatment from him; and he threatened that if any prosecutions were fairly brought before him, and the guilty parties convicted, whatever might be their rank or station in the country, though they were the first ladies in the land, they should certainly exhibit themselves in the pillory. As a judge, he recognised no distinction between the gamblers of St. James's and the pickpockets of the Strand. Lord Kenyon exerted himself to the utmost to put an end to duelling, and he declared that whoever was convicted of having murdered his fellow-creature in a duel should suffer the course of the law; and he on more than one occasion directed the jury to that conclusion, but without success. Flagitious libels against individuals were punished by him with merited severity.

But, of all writings, those partaking of the character of political libels were those against which he directed, with the most unflinching perseverance, all the terrors of the law. This was a more dangerous and delicate ground to tread upon, and people will approve or disapprove of his conduct in this particular according to the view which they take with regard to the liberty of speech upon these points. Certain it is, that since the time of Lord Kenyon the practice of prosecuting for political libels has gradually fallen into disuse; nor would the pillory, as part of the punishment for putting forth opinions, however mischievous or absurd, be at this time tolerated.

Lord Kenyon trusted too much to the power of the terrors of the law in guarding the rights of property from fraud or violence; and he inflicted death as the most terrible, and therefore the most preventive punishment. That this proceeded rather from a mistaken judgment—an ignorance of, or a want of power to give sufficient weight to, those circumstances which exert a more powerful influence upon human character, and not from a cold and sanguinary disposition, the following anecdote may be considered as a proof:—He passed sentence of death upon a young woman who had committed a theft; she fainted: Lord Kenyon, in great agitation, cried out, 'I don't mean to hang you—Will nobody tell her that I don't mean to hang her?'

Indeed, in behalf of poor and ignorant offenders who were the dupes or tools of knaves his kindly feelings were often displayed, and humble individuals of the working classes who were harassed by informers were sure to be shielded by him. A prosecution was commenced against a man for practising the trade of a tailor without having served an apprenticeship, and an attempt was made to punish him for several acts done in the same day. 'Prosecute the man,' said Lord Kenyon, 'for different acts in one day! Why not sue for penalties on every stitch?'

Lord Mansfield, when chief-justice, had somewhat unsettled the bounds of the courts of law; but Lord Kenyon, with much wisdom, reverted to the antient strictness, and he expressed his determination to maintain it. 'I have,' he said, 'been in this profession more than forty years, and have practised both in courts of law and equity; and if it had fallen to my lot to form a system of jurisprudence, whether or not I should have thought it advisable to establish different courts, with different jurisdictions, it is not necessary to say. But influenced as I am by certain prejudices that have become inveterate with those who comply with the systems found established, I find that in these proceeding by different rules, a certain combined system of jurisprudence has been framed most beneficial to the people of this country, and which I hope I may be indulged in supposing has never yet been equalled in any country on earth. Our courts of law only consider legal rights—our courts of equity have other rules by which they sometimes supersede strict legal rules, and in so doing they act most beneficially for the subject.' 'I will not,' he said, in another instance, 'overturn the law of the land as it has been handed down to me.'

He wisely refused to allow the plain words of a statute to be refined away, however severe in its enactments, by any subtle sophistry. 'The arguments,' he said, 'that have been pressed upon us might have had some effect if they were addressed to the legislature; but we are sitting in a court of law, and must administer justice according to the known laws of the land. Let application be made to the legislature to amend the act: as long as it remains upon the statute-book we must enforce it.'

Mr. Charles Butler, after praising Lord Kenyon's intuitive readiness, complains 'that he seldom exhibited the intermediate patient discussion. The consequence was, that though the decision was right, the ground of it was sometimes obscure, and the objections to it in the minds of the hearers were not always removed. This lessened the merit of his adjudications; but they are most deservedly held in the highest respect, and considered of the highest authority.'

At Nisi Prius he never brought a book with him into court to refer to. The extent as well as the arrangement of his legal knowledge needed no such assistance. In performing the laborious duties of his profession he was diligent and exact, and proceeded with so much expedition as often to get through twenty-five or twenty-six causes to the entire satisfaction of the court.

He died in 1802, sorrow-stricken by the loss of his eldest son, after having accumulated a fortune of 300,000*l.*

In his private habits Lord Kenyon was temperate, frugal even to parsimony, and an early riser. For his happiness he looked to his home, being most deeply attached to his family. He entirely disregarded outward appearance: his dress was shabby, his equipage mean, while he entirely neglected to exercise the hospitality becoming his high station and large fortune. (*Law Magazine*, No. 37, p. 49.)

KEPLER, JOHN, was born at Weil in the duchy of Wirtemberg, 21st December, 1571. He was a seven months child, very weak and sickly, and survived with difficulty a severe attack of smallpox. His parents, Henry Kepler and Catherine Guldenmann, were of noble descent, although their circumstances were far from affluent. The father, at the time of his marriage, was a petty officer in the service of the duke of Wirtemberg, and joined the army in the Netherlands a few years after the birth of his eldest son John. Upon his return to Germany he learnt that an acquaintance for whom he had incautiously become security had absconded, and had left him the unexpected charge of liquidating the bond. This circumstance obliged him to dispose of his house and nearly the whole of his possessions, and to become a tavern-keeper at Elmendingen. Young Kepler had been sent in the year 1577 to a school at Elmendingen, and he continued there until the occurrence of the event to which we have just alluded, and which was the cause of a temporary interruption in his education, as it appears that he was taken home and employed in menial services until his twelfth year, when he returned to school. In 1586 he was admitted into the monastic school of Maulbronn, where the cost of his education was defrayed by the duke of Wirtemberg. The regulations of this school required that after remaining a year in the superior classes the students should offer themselves for examination at the college of Tübingen for the degree of Bachelor. On obtaining this degree they returned with the title of veterans; and having completed the prescribed course of study, they were admitted as resident students at Tübingen, whence they proceeded in about a year to the degree of Master. During his under-graduateship Kepler's studies were much interrupted by periodical returns of the disorders which had so nearly proved fatal to him during childhood, as also by the dissensions between his parents, in consequence of which his father left his home, and soon after died abroad. Notwithstanding the many disadvantages he must have laboured under from the above circumstances, and from the confused state in which they had left his domestic affairs, Kepler took the degree of Master in August, 1591, attaining the second place in the annual examination. The first name on the list was John Hippolytus Brentius.

While thus engaged at Tübingen, the astronomical lectureship of Grätz, the chief town in Styria, became vacant by the death of George Stadt, and the situation was offered to Kepler, who was forced to accept it by the authority of his tutors, although we have his own assurance that at that period he had given no particular attention to astronomy. This must have been in the year 1593-4. In 1596 he published his 'Mysterium Cosmographicum,' wherein he details the many ingenious hypotheses which he had successively formed, examined, and rejected, concerning the number, distance, and periodic times of the planets; and finally, proposes a theory which he imagines will account in a satisfactory manner for the order of the heavenly bodies, which theory rests upon the fancied analogy between the relative dimensions of the orbits of those bodies, and the diameters of circles inscribed and circumscribed about the five regular solids. In 1597 Kepler married Barbara Muller von Muhleckh, a lady who, although two years younger than himself, was already a widow for the second time. This alliance soon involved him in difficulties, which together with the troubled state of the province of Styria, arising out of the two great religious parties into which the empire was then divided, induced him to withdraw from Grätz into Hungary, whence he transmitted to a friend at Tübingen, several short treatises—'On the Magnet,' 'On the Cause of the Obliquity of the Ecliptic,' and 'On the Divine Wisdom as shown in the Creation.' In 1600 Kepler, having learned that Tycho Brahé was at Benach in Bohemia, and that his observations had led him to a more accurate determination of the eccentricities of the planets' orbits, determined on paying him a visit, and was welcomed in the kindest manner by Tycho, by whom he was introduced the following year to the emperor, and honoured with the title of imperial mathematician, on condition of assisting Tycho in his calculations. Upon the death of Tycho, which happened in the month of October of the same year, Kepler succeeded him as principal mathematician to the emperor. To this great man Kepler was under many obligations, not merely for the pecuniary assistance and hospitality which himself and family so often experienced from Tycho, and upon which at one period they entirely depended for subsistence, but still more for the sound advice which he gave him, to abandon speculation, and to apply himself to the deduction of causes from their observed effects,—advice which Kepler greatly needed, and to which,

if he had adhered more closely, his fame would have been even greater than what it now is. It is to be regretted that upon several occasions the conduct of Kepler towards Tycho Brahe ill accorded with the generosity of the latter, though this appears to be attributable rather to the impetuosity of Kepler's temper, than to any want of gratitude towards his benefactor. It has been said that Kepler was appointed imperial mathematician on condition of assisting Tycho in his calculations. The object of these calculations was the formation of new astronomical tables generally, which were to be called the Rudolphine Tables, in honour of Rudolph the then emperor of Bohemia, who had promised, not merely to defray the expense of their construction, but likewise to provide Kepler with a liberal salary; neither of which his circumstances ever permitted him to fulfil. The part more particularly allotted to Kepler was the reduction of Tycho's observations relative to the planet Mars, and to this circumstance is mainly owing his grand discovery of the law of elliptic orbits, and that of the equable description of areas. The pecuniary difficulties however in which he found himself almost incessantly involved in consequence of the non-payment of his salary, greatly retarded the progress of his labours, and obliged him to seek a livelihood by casting nativities. The Rudolphine Tables were therefore postponed, and he applied himself to works of a less costly character, from which he might expect to derive more immediate remuneration. In 1602 appeared his 'Fundamental Principles of Astrology;' in 1604 his 'Supplement to Vitellion;' in 1605 'A Letter concerning the Solar Eclipse;' and in 1606 'An Account of the New Star which had appeared in 1604 in the Constellation Cassiopeia.' Of these the 'Supplement to Vitellion' was important, as containing the first consistent theory of that branch of optics termed dioptrics.

At length, in 1609, appeared his 'New Astronomy,' containing his great and extraordinary book 'On the Motion of Mars;' a work which holds the intermediate place, and is the connecting link, between the discoveries of Copernicus and those of Newton. The introduction is occupied in refuting the then commonly-received theory of gravity, and in declaring what were his own opinions upon the same subject. In the course of this discussion he states distinctly that since the attractive virtue of the moon extends as far as the earth, as is evident from its enticing up the waters of the earth, with greater reason it follows that the attractive virtue of the earth extends as far as the moon, and much farther; and he likewise asserts that if two bodies of like nature be placed in any part of the world near each other, but beyond the influence of any other body, they would approach each other like two magnets, each passing over a space reciprocally in proportion to its mass; so that if the moon and earth were not retained in their orbits by their animal force, or some other equivalent to it, the earth would approach the moon by the 54th part of their distance, and the moon would approach the earth by the remaining 53 parts. Previous to the publication of this remarkable work it was supposed that each planet moved uniformly in a small circle, called an *epicycle*, the centre of which epicycle moved with an equal angular velocity in the opposite direction round the centre of the earth, thus describing a larger circle which was called the *deferent*. Subsequent observations being found irreconcileable with the foregoing hypothesis, it was modified by supposing the uniform angular motion of the epicycle to be described about a point not coinciding with the centre of the earth, a necessary consequence of which supposition was that the linear motion of the epicycle ceased to be uniform. The work of Copernicus 'De Revolutionibus Orbium Cœlestium' had appeared in 1543, wherein he considers the sun to be the fixed centre about which the planets move with uniform motions, but retains the complicated machinery of the deferent and epicycle in order to account for the variations arising from the actual inequality of the planet's motion. The system of Tycho Brahe himself was identical with one which Copernicus had rejected, and consisted in supposing the sun to revolve about the earth, carrying with it all the other planets revolving about him; and indeed Tycho not only denied the revolution of the earth about the sun, but likewise its diurnal rotation upon its axis. Such is an imperfect outline of the theory of the universe before the time of Kepler. The theory adopted by Kepler, in the early part of his discussion of Tycho's observations, appears to have been that the orbit of each planet, including the earth, was circular; that it was described with a uniform angular velocity about a point within, called the centre of the equant, and that the centre of the orbit lay in the line joining the centre of the equant and the place of the sun, but not equidistant between those points, as had been previously supposed. With respect to the earth however, in particular, he had started with the erroneous opinion, then generally entertained by all astronomers, that the centre of the earth's equant coincided with that of its orbit, and that consequently not only its angular but also its linear motion was uniform, although its distance from the sun was known to vary. After four years of laborious calculation, the non-accordance of his results with observation obliged him to fix upon the bisection of the line joining the centre of the equant and the place of the sun, for the centre of the planet's orbit; and shortly after he was led to the conclusion that one of the two other principles upon which his theory rested must be erroneous; that either the orbit of the planet was not a perfect circle, or that there was no point within it round which it moved with a uniform velocity.

Having easily proved that at the apsides, that is, the two points of the planet's orbit which are nearest to and farthest from the sun,—the times of describing equal small arcs are nearly proportional to the distances of the planet from the sun, he concluded with his accustomed precipitancy that the same relation existed at all other points of the orbit. An almost immediate consequence of this assumption was that the time of describing an arc of any length whatever would be proportional to the sum of all the lines which could be drawn from the sun to every point of that arc; but as the calculation of these distances was found to be excessively operose, he substituted the approximate area of the figure bounded by the arc and the two extreme distances for the sum of all the distances, and was thus led from erroneous principles to that beautiful law of the planetary motions by which the area described by the revolving radius vector is proportional to the time of its description. When however he came to apply this theory to the motion of Mars, the excentricity of whose orbit is much greater than that of the Earth's, he found that the circular hypothesis gave results differing from the observations of Tycho by at least eight minutes, and as he considered that difference too great to be attributed to the error of so exact an observer, he concluded that the suspicions, which, as was above stated, he had long previously entertained, relative to the form of the planets' orbits, were well founded, at least with respect to the planet Mars. At length, he deduced from observations of that planet near the quadratures, that its orbit was an oval elongated in the direction of its apsides, and was thus led to the law of elliptic motions.

The elliptic form of the orbits and the equable description of areas constitute two of the three celebrated truths known by the name of Kepler's laws. The third, viz. that the squares of the periodic times are proportional to the cubes of the mean distances from the sun, was not discovered till twelve years after, although, before the publication of his 'Mysterium Cosmographicum,' he had been speculating, as we have seen, upon finding some relation between those distances and periodic times. The final discovery resulted, far less from philosophical deduction, than from the innumerable combinations which his ever-active fancy had been calling into existence during the previous seventeen years; and indeed when he at length detected the relation which he had so long been in search of, he was only able to offer an explanation of it upon four suppositions, three of which are now known to be false.

In 1620 Kepler was visited by Sir Henry Wotton, the English ambassador at Venice, who finding him, as he was always to be found, oppressed with pecuniary difficulties, urged him to go over to England, where he assured him of a welcome and honourable reception; but Kepler could never determine on quitting the Continent. In 1624 he went to Vienna, where with difficulty he obtained 6000 florins towards completing the 'Rudolphine Tables,' together with recommendatory letters to the states of Suabia, from whom he also collected some money due to the emperor. It was not however till 1627 that these tables—the first that were calculated on the supposition that the planets move in elliptic orbits—made their appearance; and it will be sufficient to say of them, in this place, that had Kepler done nothing in the course of his whole life but construct these, he would have well earned the title of a most useful and indefatigable calculator. In 1630 he made a final attempt

to obtain a liquidation of his claims upon the imperial treasury, but the fatigue and vexation of his fruitless journey brought on a fever which terminated his life in the early part of November, 1630, and in his 59th year. His body was interred in St. Peter's churchyard at Ratisbon, and a simple inscription, which has long since disappeared, was placed on his tombstone. Upon the character of Kepler, upon his failures, and on his success, Delambre has pronounced the following judgment:—'Ardent, restless, burning to distinguish himself by his discoveries, he attempted everything; and having once obtained a glimpse, no labour was too hard for him in following or verifying it. All his attempts had not the same success, and, in fact, that was impossible. Those which have failed seem to us only fanciful; those which have been more fortunate appear sublime. When in search of that which really existed, he has sometimes found it; when he devoted himself to the pursuit of a chimera, he could not but fail; but even there he unfolded the same qualities, and that obstinate perseverance that must triumph over all difficulties but those which are insurmountable.'

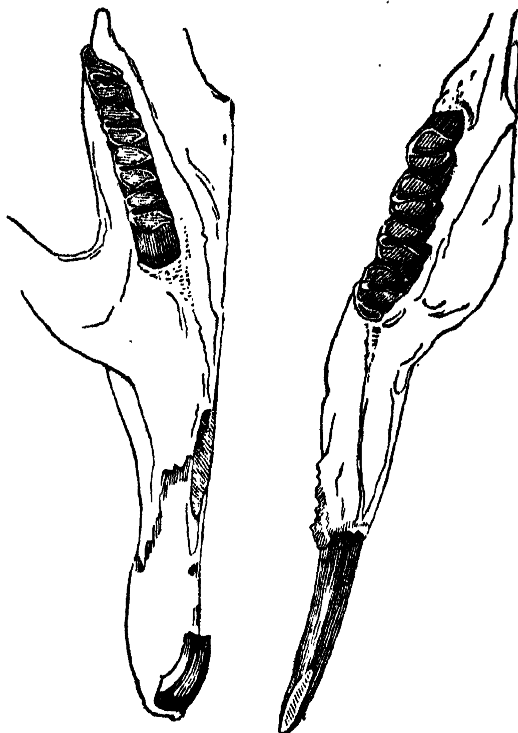
The following is a list of Kepler's published works. His manuscripts were purchased for the library of St. Petersburg, where Euler, Lexell, and Kraft undertook to examine them and to select the most interesting parts for publication, but the result of this examination has never appeared.

List of Kepler's published works:—'Ein Calender,' Gratz, 1594; 'Prodromus Dissertat. Cosmograph.,' Tübingæ, 1596, 4to.; 'De fundamentis Astrologiæ,' Pragæ, 1602, 4to.; 'Paralipomena ad Vitellionem,' Francofurti, 1604, 4to.; 'Epistola de Solis deliquio,' 1605; 'De Stellâ Novâ,' Pragæ, 1606, 4to.; 'Vom Kometen,' Halle, 1608, 4to.; 'Antwort an Röslin,' Pragæ, 1609, 4to.; 'Astronomia Nova,' Pragæ, 1609, fol.; 'Tertius Interveniens,' Frankfurt, 1610, 4to.; 'Dissertatio cum Nuncio Sidereo,' Francofurti, 1610, 4to.; 'Strena, seu De nive sexangulâ,' Frankfurt, 1611, 4to.; 'Dioptrica,' Francofurti, 1611, 4to.; 'Vom Geburts Jahre des Heylandes,' Strasburg, 1613, 4to.; 'Respons. ad epist. S. Calvisii,' Francofurti, 1614, 4to.; 'Eclogæ Chronicæ,' Frankfurt, 1615, 4to.; 'Nova Stereometria,' Lincii, 1615, 4to.; 'Ephemerides 1617—1620,' Lincii, 1616, 4to.; 'Epitomes Astron. Copern. Libri i. ii. iii.,' Lentiis, 1618, 8vo.; 'De Cometis,' Aug. Vindelic., 1619, 4to.; 'Harmonice Mundi,' Lincii, 1619, fol.; 'Kanones Pueriles,' Ulmæ, 1620; 'Epitomes Astron. Copern. Liber iv.,' Lentiis, 1622, 8vo.; 'Epitomes Astron. Copern. Libri v. vi. vii.,' Francofurti, 1622, 8vo.; 'Discurs von der grossen Conjunction,' Linz., 1623, 4to.; 'Chilias Logarithmorum,' Marpurgi, 1624, fol.; 'Supplementum,' Lentiis, 1625, 4to.; 'Hyperaspistes,' Francofurti, 1625, 8vo.; 'Tabulæ Rudolphinæ,' Ulmæ, 1627, fol.; 'Resp. ad epist. J. Bartschii,' Sagani, 1629, 4to.; 'De anni 1631 Phænomenis,' Lipsæ, 1629, 4to.; 'Terrentii Epistolium cum Commentatiunculâ,' Sagani, 1630, 4to.; 'Ephemerides,' Sagani, 1630, 4to.; 'Somnium,' Francofurti, 1634, 4to.; 'Tabulæ Manuales,' Argentorati, 1700, 12mo.

(Abridged from the *Life of Kepler*, in the 'Library of Useful Knowledge;' with occasional reference to the *Système du Monde* of Laplace, and other works.)

A splendid edition of Kepler's 'Correspondence' was published under the auspices of the Emperor Charles VI., in 1718, by M. G. Hansch. It is entitled 'Epistolæ ad J. Keplerum,' &c., and the title-page has no place of publication, but the preface is dated from Leipzig. It contains a Life of Kepler.

KERMAN. [PERSIA.]



KERMANSHAW. [PERSIA.]

KERMES MINERAL, a peculiar sulphuret of antimony, formerly much, but now little used in medicine. Various processes, some in the humid and others in the dry way, have been proposed for obtaining it.

One of the best appears to be that of boiling six parts of powdered sesquisulphuret of antimony in a solution of about twenty times its weight of crystallised carbonate of soda in ten times its weight of water. After an hour's ebullition, the liquor is to be strained while hot, and allowed to cool very slowly, during which the Kermes Mineral separates in the state of a brownish-red powder, which, after due washing, is to be dried with a gentle heat.

According to Rose it is composed of sulphur 38·41 and antimony 61·59, which are very nearly in the proportion of 2½ equivalents of sulphur 40 + one equivalent of antimony 65.

KE'RODON, a genus of rodents, bearing in some respects resemblance to that of *Cavia*, but differing both in the locomotive and masticatory organs, established by M. F Cuvier. Dental formula:—Incisors $\frac{2}{2}$, molars $\frac{4-4}{4-4} = 20$

Teeth of Kerodon. (F. Cuvier.)

The molars all resemble each other, and are composed of two equal parts, each of a triangular or rather cordiform shape, united on the external side of the tooth, and separated on its internal side. These triangles or 'hearts' are each surrounded by their enamel, and filled with bony matter, and their separation produces an angular notch partly filled with cortical substance.

When M. F. Cuvier wrote, but one species, *Kerodon Moco*, was known, and this was discovered by Prince Maximilian of Neuwied, and noticed by him under the name of *Cavia rupestris*. The fur is ash-gray mixed with reddish yellow, and blackish above and whitish below. Size smaller than that of the guinea pig.

This species was found in the rocky places of the interior of Brazil near Rio San Francisco.

In 1836, Mr. Bennett exhibited to a meeting of the Zoological Society of London a rodent sent home among the animals collected by Captain Phillip Parker King, R. N., during his survey of the Straits of Magalhaens, and presented by him to the Society, which Mr. Bennett regarded as a second species of *Kerodon*, and for which he proposed the name of *Kerodon Kingii*. It was chiefly distinguishable from that discovered by Prince Maximilian by its more uniform colour. Excepting a slight dash of white behind the ear, and a longer line of the same colour marking the edge of each branch of the lower jaw, the animal is entirely gray; the upper surface being distinguished from the under by a greater depth of tint, and by the intermixture of a free grizzling of yellow and black. The crowns of the mo'ar teeth, as in the typical species, consist of bone surrounded by two triangles of enamel, the bases of which are connected by a short line of enamel passing from one to the other, all the lines being slender and sharply defined.

This species was found at Port Desire, on the eastern coast of Patagonia. (*Zool. Proc.*, 1835.)

KERRY, a maritime county of the province of Munster, in Ireland; bounded on the east by the counties of Limerick and Cork, on the south by the county of Cork and the æstuary of the river of Kenmare, on the west by the Atlantic Ocean, and on the north by the æstuary of the river Shannon, which separates it from the county of Clare. According to the map published under the superintendence of the Society

for the Diffusion of Useful Knowledge, Kerry is situated between 51° 41′ and 52° 33′ N. lat., and between 9° 7′ and 10° 30′ W. long. The greatest length in a direct line north and south is from the Priest's-leap mountain, on the Cork boundary, to Carrigfoyle on the Shannon, 54½ statute miles; and the greatest breadth in a direct line east and west is from the Cork boundary at Lisheen to Dunmore Head, the most westerly point of the mainland of Ireland, 56 statute miles. In a direct line from south-west to north-east, between Bolus Head and the Limerick boundary at Tarbert, the distance is 69 miles. The coast line with its various indentations is above 220 miles. The area, as estimated in the above map, is 1,068,480 statute acres, or 1669 square statute miles. It has been elsewhere estimated at 1,148,720 acres, of which 581,189 acres are cultivated land, 552,862 are unprofitable mountain and bog, and 14,669 are under water. In 1831 the gross population was 263,126.

Kerry, with a small portion of Cork, forms the south-western extremity of Ireland. The coast, which is bordered by the Atlantic, is deeply indented by the æstuary of the Kenmare river, the bay of Dingle, and the bay of Tralee, the two former of which penetrate into the mainland about 30 miles in an easterly direction.

The peninsulas intercepted between these arms of the sea are occupied by the western extremities of the mountain system, which, commencing in Waterford, extends with little interruption across the entire south of Ireland. The mountains of Bear and Bantry, spreading from the south-western boundary of Cork across the south of Kerry, occupy the district between the river of Kenmare and the bay of Dingle. The peninsula intercepted between the bays of Dingle and Tralee consists in like manner of a prolongation of the mountain groups which occupy the north-western extremity of Cork and the south-west of Limerick: the heights connecting the extremities of this latter series of elevations extend across the middle of the county in a line nearly east and west. Between the above-mentioned mountain-ranges there is a considerable plain, formed by the subsidence of the high table-land, which occupies the middle portion of the Cork boundary, and spreads with a gradual declivity towards the head of Dingle or Castlemain Bay. Beyond the range of mountain which crosses the centre of the county extends a rich and generally level country, which rises into rough land in only one direction, towards Kerry Head on the Shannon.

At the head of the river Kenmare, which is in fact an arm of the sea, is a long and narrow valley, which is watered by the Roughty, the most considerable stream that falls into the Kenmare æstuary. The town of Kenmare is situated at the lower extremity of this valley in a fertile but confined tract, from which the Glancrought mountains rise on one side towards Cork, and the group of Mangerton on the other, towards that extensive mountain-tract which occupies the entire peninsula between the northern shore of Kenmare river and the bay of Dingle.

The extremity of this great peninsula, comprising the barony of Iveragh and part of the barony of Dunkerron, is divided into three principal valleys by ridges running nearly north-east by south-west. Of these valleys the first towards the north is separated from the bay of Dingle by a steep range terminating towards the head of the bay in the mountain of Drung, and prolonged westward to the coast at Dowlus Head, opposite to which the island of Valentia, half a mile from the opening of the valley, includes between it and the mainland one of the safest harbours in Ireland. The town of Cahirciveen is situated at the foot of this valley, where the river Fartagh expands into a small lake before falling into Valentia Harbour. Separated from the valley of the Fartagh by a ridge of the same mountain-group is another valley terminating towards the sea in the open bay of Ballinaskelligs, so called from the Skelligs, two remarkable rocks in the offing. The boundary of the bay of Ballinaskelligs on the north is Bolus Head, the extremity of the mountain-range above mentioned. Between this range and the Dunkerron mountains, on the south-east and east, then is a considerable extent of comparatively open country, subdivided into two valleys by the secondary ridge of Cahirbarna. Of these valleys that to the west is drained by the Inny, which has its sources about 20 miles in the interior at a great elevation, among the Iveragh mountains. On the opposite side of Cahirbarna lie three lakes, of which Loch Currane is the most considerable: it is supposed at one time to have been an arm of the sea, and, owing to an accumulation of detritus at its mouth, to have been converted into a basin for the waters descending from the lakes above. The village of Waterville is situated at the point where it discharges itself into the sea. The southern boundary of the bay of Ballinaskelligs is formed by the extremity of the Dunkerron range, which terminates in lofty mountains above Derrynane, from which point their general direction is north-east, nearly parallel to the northern shore of the æstuary of Kenmare. Between the main range and the shore of this arm of the sea there are numerous lateral valleys drained by mountain streams running nearly north and south. Of these the principal are the valleys of Sneem and the little Blackwater. Throughout this district the only spots of cultivated ground are either on the sea-coast, the banks of rivers, or along the upper margins of the bogs which universally occupy the valleys to a considerable height up the acclivities of the mountains. In the barony of Iveragh alone are 26,896 Irish, or 43,599 statute acres of bog, among which the several mountain-chains appear insulated.

The Iveragh mountains are bounded on the north-east by by the lateral valley of Glencare, which runs southward from the upper end of Dingle Bay towards the head of the similarly situated valley of Sneem, on the opposite side of the peninsula. Loch Carra, a considerable expanse of water, occupies the lower portion of the valley of Glencare, above which, in the recesses of the mountain, are the villages of Blackstones and Carramore. In the interior and opposite the extremity of the central ridge of Iveragh, is situated the great group of MacGillicuddy's Reeks, among which Carran Tual rises to the height of 3410 feet, being the highest ground in Ireland. The Reeks extend about ten miles in a direction from north-west to south-east, subsiding into the plain at the head of Dingle Bay on the north, and separated from the external range of Tomies and Glenà by a deep chasm called the Gap of Dunloe, on the north-east. In a deep hollow between the south eastern flank of this range and the group of Mangerton, which connects the extremity of the Dunkerron chain with the Priest's-leap and Glanerought mountains, lies the Upper Lake of Killarney. This beautiful sheet of water, which is three miles in length by three-quarters of a mile in breadth, is enclosed on all sides by mountains from 2000 to 3000 feet in height, except at one point, towards its eastern extremity, where it discharges its waters by a tortuous course of three miles between the southern declivities of Glenà and the precipitous side of Turk mountain, which forms a portion of the group of Mangerton.

There are several wooded islands in the Upper Lake, the luxuriant foliage of which forms an agreeable contrast to the general sterility of the surrounding mountains. There is however a considerable tract of natural oak forest towards its southern extremity, and the channel leading to the Lower Lake passes through a thickly wooded defile About midway between the extremities of the channel a remarkable detached rock, called the Eagle's Nest, rises over the left bank to a height of 1100 feet: the echoes here are of unusual continuance and distinctness. Emerging from this defile, the river expands into the Lower Lake of Killarney, seven miles in length by three in breadth, skirting the eastern declivities of the mountain range of Tomies and Glenà. These mountains, descending abruptly to the western verge of the lake, are clothed with the richest natural woods of oak, ash, pine, alder, and beech, intermixed with hazel, whitethorn, yew, holly, and arbutus, from a height of several hundred feet down to the water's edge through a continuous distance of six miles. O'Sullivan's river, descending by a thickly wooded ravine on this side, forms a cascade 70 feet high close to the shore of the lake. On the opposite side the low alluvial banks are everywhere broken into promontories and islands, on which the arbutus grows with uncommon luxuriance. The town of Killarney is situated on the plain about a mile from the eastern shore; half a mile south of Killarney runs the Flesk, the chief feeder of the lake. About a mile south from the embouchure of the Flesk, the richly wooded promontory of Muckruss, running into the lake about a mile and three-quarters, separates a portion of the lake which is called the Lake of Muckreefs, and sometimes Turk Lake, from its skirting the base of that mountain. Two cascades descend into Turk Lake: of these the more considerable is fed by a pool called the Devil's Punchbowl, situated at a height of 1700 feet on the ascent of Mangerton mountain, which, between the vale of Killarney and the town of Kenmare, rises

to a height of 2550 feet. The castles of Dunlo and Ross, and the ruined churches of Aghadoe and Muckreefs, which are all situated on the eastern shore of the Lower Lake, add considerably to the interest and extent of the surrounding scenery. The waters of the lakes of Killarney discharge themselves at the northern extremity of the Lower Lake through the river Laune, which runs by a course of twelve miles into the head of Dingle Bay.

The remainder of the plain between Killarney and the mountains south of Tralee is drained by the river Main, which rises near the Cork boundary, and after passing the towns of Castle Island and Castlemain, discharges itself into the head of Dingle Bay, where it forms an æstuary called Castlemain Harbour.

The valley of the Main is bounded on the north by the group of the Stack mountains, which sink into comparatively low hills as they trend towards the sea, leaving a pretty open communication with Tralee from the south. Westward from this point the lofty ridge of Slievemish occupies the entire neck of the peninsula of Corkaguinny, which bounds the bay of Dingle on the north. Slievemish is interrupted by a lateral valley, beyond which the conical mountain of Cahirconree rises to a height of 2784 feet. Westward from this a minor chain of hills extends to Dingle on the southern side of the peninsula; beyond and north of Dingle the mountains rise towards the Atlantic in great masses, of which the chief is Brandon, 3150 feet in height, being the second highest ground in Ireland. The extremity of the peninsula has an abrupt coast of about six miles from north to south, formed by Sybil Head, Maran mountain, Eagle mountain, and Dunmore Head, off which lie the Blasquet Islands.

North of Tralee the country improves in facility of access and cultivation. The plain of Ardfert, between Tralee and the high ground towards Kerry Head, is rich and well improved; its drainage is towards the sea, and the streams are insignificant. The remaining district, extending from the plain of Ardfert to Tarbert on the Limerick boundary, is the most extensive tract of open country in Kerry; it is drained by the rivers Feale, Gale, and Brick, which, uniting within five miles of the sea, receive the common name of the Cashen river: the united length of their courses is about 50 miles. A rough district extends from the mouth of the Cashen to Beal Point, where the æstuary of the Shannon first assumes the character of a river. The coast is here precipitous towards the sea, and near the bathing village of Ballybunion abounds in caves which are said to be of the most magnificent description. On the Feale is situated the town of Listowel, which, with Lixnaw near the Brick, and Tarbert and Ballylongford on the Shannon, are the only other places of consequence in the county. The district of the Cashen contains a large extent of bog. The total area of the bogs of Kerry is estimated at 150,000 acres.

The harbours on the south side of the river of Kenmare are in general badly protected from westerly and northerly gales. From Dutch Island, which fronts the harbour of Ardgroom on this side, as far up as the tide runs, there is safe anchorage in eight to three fathoms water in the middle of the channel, the banks being a soft ooze on which vessels may be conveniently careened. Opposite to Ardgroom, on the north side of the æstuary, is Sneem Harbour, where vessels may lie landlocked in four fathoms water, or in the entrance may ride in ten fathoms. Vessels parting their cables in any part of the æstuary may safely run aground in Nideen Sound, which forms the upper extremity of the bay on this side. Towards the middle of the west side of Ballinaskellys Bay is a small island, between which and the mainland is anchorage in four to five fathoms, but even here in hard weather a vessel requires very strong cables; the remainder of the bay is quite unsafe in southerly or westerly winds. Between Bolus Head and Puffin Island is St. Finian's Bay, which is very much exposed to the prevalent run of the sea. The harbour of Valentia opens about a league to the north of Puffin Island; it possesses the advantage of a double entrance, so that ships may sail in or out with any wind. It is quite landlocked, but the entrances are narrow, that on the north being contracted by the islands of Beginnis and Lamb's Island, between the former of which and Valentia there is a sunken rock, which farther contracts the entrance to a cable's length. Valentia Island forms the southern boundary of the bay of Dingle towards the sea. Dingle bay is open and unsafe, being full of shoals at its upper extremity; vessels embayed here should make either for Valencia or the creek of Dingle on the opposite side of the æstuary. [DINGLE.] A league west of Dingle creek is the bay of Ventry, with good anchorage and a sufficient depth of water, but open to the south. Smerwick harbour on the opposite side of the peninsula has also deep water and good holding-ground, but is exposed to the north: the bottom of the harbour consists of turf bog, which shows that a portion of this coast must have been submerged within a comparatively recent date. Under the neck of the peninsula on the northern side is the bay of Tralee, which is dry at low water, but now in process of considerable improvement by the construction of a ship canal, by which vessels of 300 tons will be able to come up to the town. [TRALEE.] From Tralee northward the coast is low and encumbered with shoals and sandbanks. Vessels embayed here, if they cannot make Fenit Creek on the north of Tralee Bay, have no shelter for a distance of two leagues. Beyond Kerry Head opens the æstuary of the Shannon, in which the first sheltered anchorage is off the point of Tarbert, where ships may lie nearly landlocked in twelve fathoms water. There are piers for fishing boats and small craft at Kenmare, Ballinaskelligs, Cahirciveen, Brandon, and Barra; and considerable improvements are projected at Ballylongford and Tarbert.

The roads in the south-western part of Kerry up to the year 1820 were scarcely passable for wheel-carriages, and there are some parts of the coast between Kenmare and Cahirciveen still inaccessible, except on foot or horseback. From Cahirciveen the old line of communication was by the seaward side of Drung Mountain, at a height of 800 feet above the Bay of Dingle. The difficulty of access to the district of Glanlehy situated southward of this line induced the proprietor, Lord Headly, in 1807, to commence the construction of a road on a more eligible level through his property: the development of the resources of the district which followed the first opening of this road was remarkably rapid; and the same result in a more striking manner attended the subsequent construction of a mail-coach road, connecting Cahirciveen, by the valley south of Drung Mountain, with the low country at the head of Dingle Bay. In three years from the opening of the new road in 1821, there were upwards of twenty two-story slated houses built in Cahirciveen, together with an inn, a bridewell, a post-office, a chapel, a quay, a salt-work, and two large stores for grain. Before this time the village consisted of a few thatched cabins, and the nearest post-office was thirty miles distant. About the same time government commenced several new lines of road, which have since greatly contributed to the prosperity of the country. Of these the most important is a line 25 Irish or 32 statute miles in length, connecting the town of Listowel and the northern parts of Kerry with Newmarket in the county of Cork, by which the distance from the former town to Cork city is diminished 29 miles. Another line 25½ statute miles in length connects Castle Island with Newcastle in the county of Limerick, diminishing the former distance from Killarney and the southern parts of Kerry to Limerick city 29½ statute miles. The old roads in this direction had in some places a rise of 1 foot in 4; the present road has a maximum rise of 1 foot in 27½. It crosses the Feale River by one arch of 70 feet span, where formerly was a bridge of twenty-one arches. Before the year 1824 there was no road passable for wheel-carriages between Kenmare and the south-western part of Cork, and the car-road from Kenmare to Killarney was of the worst description. An excellent road has since been constructed between the two latter places, and the line across the mountains of Bear and Bantry is now in progress. These lines will be united at Kenmare by a suspension-bridge, to which the Marquis of Lansdowne contributes 3200*l.* This will complete a direct and very important line of communication between the Shannon at Tarbert, and the south coast of the county of Cork near Skibbereen, a total distance of 84 miles. The other roads of the county are constructed and kept in repair by grand jury presentments.

The climate is very moist from the vicinity of the Atlantic, and the south-western district is much exposed to storms. In the inland parts however, especially in the neighbourhood of Killarney, the air is mild and genial, and vegetation extremely luxuriant. There have been some remarkable instances of longevity in this county, notwithstanding the prevalent use of ardent spirits.

The geological structure of the chief mountain-chains is similar to that of the mountains in the west of

Cork, the main component being a red or grey conglomerate and sandstone supporting flanks of silicious flags, and overlaid in the low districts by fields of floetz limestone. It is observed, that the arms of the sea which penetrate this county lie within the limestone troughs, that rock appearing at the upper extremity of each, while the promontories forming their sides consist of sandstone and conglomerate. The chief limestone fields occupy the basins of the Feale, Main, and Roughty, which last runs into the head of the æstuary of Kenmare. At the Roughty it is cream-coloured, hard, slaty, and has a vitreous fracture. Along the Main it lies in strata, generally compact, much impressed with marine remains, and towards Tralee is black and dressed as marble; it is of a lighter colour and softer in the direction of Castle Island, where it burns readily for manure. From Ardfert to Listowel, and thence north to Knockanure Hill, it is of a light smoke-colour, and rises occasionally in low crags from which it is procured with great facility. Northward from Ardfert the country towards Kerry Head consists of thick beds of argillaceous sandstone, beyond which the limestone reappears in contact with beds of alum slate in the cliffs of Ballybunion. This formation, which is the most extensive at present known, extends from Ballybunion to Baltard Point in the county of Clare, a distance of 30 miles. From Tralee eastward the country rising towards the boundaries of Cork and Limerick is occupied with an extension of the great Munster coal district. The upper strata of this tract consist chiefly of an indurated clay and has with ochreous partings covering thin beds of anthraceolite or culm: those on the eastern extremity of the district have been found alternating with good coal-blende similar to that of Kilkenny, and have been wrought to a considerable extent, but not in this county.

The mountains of Glanbehy abound with iron-ore, which was formerly smelted in considerable quantities at Blackstones, in works erected by Sir William Petty, but, the supply of timber having failed, these works were given up about the year 1750. An iron bloomery was also worked at one time at Killarney, the neighbourhood of which, as appears by some verses in Nennius, has been celebrated for its mines since the ninth century. At Muckruss and Ross Island in the Lower Lake, copper-mines have been worked occasionally since about the year 1750, but are now discontinued. Lead-ore has also been found in considerable quantities in the vicinity of the lake. Copper-ore has been found at Ardfert and in Glanerought. Works for extracting copperas were at one time in operation near Castle Island, but are now given up. The slate quarry in Valentia, the working of which is carried on by the Knight of Kerry, produces flags to the amount of 1800*l.*, and slates to the amount of 500*l.* annually. The flagging, which is of a very superior description, is bought at the quarries by a stone-merchant, who transports it to London, where there is a demand for it which, it is expected, will be limited only by the power of production. In size, appearance, and strength, these flags surpass every other description of flagging in use in London.

The soil of the south-western district, where not encumbered with bogs, is an adhesive loam, fit for the reception of corn crops, and formed by the decomposition of the clay-slate rock, which, from the nearly vertical position of its strata, is readily disintegrated by the weather. Up to the year 1810 the plough was totally unknown in the more western parts of this district, and spade cultivation is still practised to a considerable extent. The improvements on the estates of Lord Headly and the Marquis of Lansdowne have latterly given an impetus to agricultural labour throughout the southern parts of the county, which has caused a marked alteration for the better in the farms and dwellings of the peasantry. The soil of the middle district is a rich loam, which produces excellent crops of grain, and when laid down in pasture yields butter of prime quality. The northern district has a stiffer soil, more retentive of wet, and inclined to run to rushes. It also is grazed to a considerable extent by dairy farmers, who find a market for their butter in Tralee. Cider is made here in large quantities, and of a superior quality. The condition of the peasantry however is inferior to that of the inhabitants of the southern districts. The average rate of labourers' wages in the south is 8*d.* per day, and in the northern parts from 6*d.* to 8*d.* The system of farming, except where the example of the great proprietors has caused some change in the rotation of crops, is not judicious. Green crops are generally unknown, and grass seeds are little in use. The native breed of cattle are very small, but well formed, good milkers, and easily fattened. They are now chiefly met with in the mountain districts: the dairy farms and low pastures are stocked with the ordinary cattle of the country. A breed of small ponies is peculiar to Kerry; they are too light for farming purposes, but answer for the saddle very well, and are sold in considerable numbers throughout the country. The peasantry of the southern districts are distinguished by the darkness of their complexion, and a peculiar cast of features which has been generally thought to indicate a Spanish origin.

The chief trade of the county consists in exports of agricultural produce, chiefly oats and butter. The returns are defective, but it is estimated that 100,000 firkins of butter are annually sold in the markets of Tralee and Killarney. The manufacture of linen is carried on with some activity in the neighbourhood of Dingle, the linens from which place were formerly in much repute. There is also a general manufacture of coarse woollens throughout the county for home consumption.

In 1836 the fisheries on this coast gave occasional employment to 1 decked boat, 44 half-decked boats, 421 open sail-boats and 610 open row-boats, manned by 6311 fishermen. The condition of the fishermen has been gradually declining for the last thirty years: many of the men have emigrated and left their families mendicants. The fish caught are turbot, haddock, gurnet, pollock, plaice, soles, dorees, mullet, mackerel, herrings, pilchards, &c., with a plentiful supply of oysters, crabs, lobsters, and scallops. Great numbers of seals formerly frequented the river of Kenmare and the caves of Ballybunion; but they have latterly become more shy, and are now rarely caught.

Kerry is divided into the baronies of Iveragh on the south-west, containing the town of Cahirciveen, population (in 1831) 1192: Dunkerron, occupying the remainder of the peninsula, containing only hamlets: Glanerought on the south-east, containing the town of Kenmare, pop. 1072: Magonihy, in the centre, containing the town of Killarney, pop. 7910: Trughenacmy, north of Magonihy, containing the borough of Tralee, pop. 9568; and the towns of Castle Island, pop. 1570; Miltown, pop. 1429; Killorglan, pop. 896; Blennerville, pop. 532; Castlemain, pop. 387: Corkaguiney, occupying the peninsula between Dingle and Tralee bays, containing the towns of Dingle, pop. 4327; Castle Gregory, pop. 970; and Stradbally, pop. 425: Clanmaurice on the north-west, containing the town of Ardfert, pop. 717: and Iraghticonnor on the north and north-east, containing the towns of Listowell, pop. 2289; Ballylongford, pop. 1300; and Tarbert, pop. 956.

Prior to the Union, Kerry sent eight members to the Irish parliament: two for the county, and two for each of the boroughs of Tralee, Dingle, and Ardfert. It is represented in the Imperial parliament by two county members, and one for Tralee borough. The county constituency in 1836 was 1212. The assizes are held at Tralee, and quarter-sessions at Tralee and Killarney; there are bridewells at

Killarney, Dingle, Kenmare, Cahirciveen, Castle Island, Miltown, Listowell, and Tarbert. The total numbers of persons committed for trial to the county goal in 1836 was 747, of whom 503 were convicted. Of the offenders, at the time of their commitment, 283 males and 3 females could read and write, 123 males and 8 females could read only, and 243 males and 87 females could neither read nor write. The constabulary force in 1835 consisted of 7 first class constables, 26 constables, 130 sub-constables, and 11 horse; the total cost of the establishment for that year was 5818*l.* 5*s.* 8*d.*, of which 2830*l.* 5*s.* 3*d.* was chargeable against the county. The county infirmary and fever hospital are at Tralee; there is also a fever hospital at Killarney, and there are dispensaries, supported by voluntary contributions and grand jury presentments, in all the minor towns. The district lunatic asylum is at Limerick; the proportion of the cost of its erection chargeable against Kerry county is 9303*l.* 16*s.* 7*d.* Kerry is entirely within the diocese of Ardfert and Aghadoe. The proportion of Roman Catholics to Protestants in this diocese is nearly 40 to 1. The proportion per cent. of the population under daily instruction is 4·63, in which respect this diocese stands last among the 32 dioceses of Ireland. There is however a very general turn for classical learning among the peasantry, many of whom have a tolerable knowledge of the Latin language.

Kerry, according to some Irish writers, had its name from Ciar, the son of Fergus, king of Ulster, and signified Ciar's kingdom; and originally formed part of the kingdom of Desmond, or South Munster, of which the Mac Carthies were sovereigns. Dermod MacCarthy, chief of this country, having invited the assistance of Raymond le Gros, one of the early Anglo-Norman adventurers, to suppress the rebellion of his son Cormac, granted him as a recompense for his services a large tract in the north of the county round Lixnaw, where Raymond, about A.D. 1177, settled his son Maurice, from whom the Fitzmaurices, lords of Kerry, draw their pedigree, and the barony of Clanmaurice takes its name. Soon after, the Fitzgeralds established themselves in the south of the county, where they rose to such power on the downfall of the MacCarthies that in 1295 Thomas Fitzmaurice Fitzgerald was captain of all Desmond, comprising the counties of Cork, Waterford, and Kerry, and lord justice of Ireland. He left two sons, John, afterwards created earl of Kildare, and Maurice, created earl of Desmond, with a royal jurisdiction over the palatinate of Kerry, A.D. 1329. The liberty of Kerry so erected included the entire county, with the exception of the church lands, for which the king appointed the sheriff. The lords of the palatinate had their own courts, judges, and great law officers, the only distinction between the liberty and a regular county being that the executive was administered by a seneschal instead of a sheriff. The possession of so great powers in a district removed from all direct control drew the succeeding earls of Desmond into frequent contempts of the royal authority, for which their territories were on several occasions wasted by the king's forces. The rebellion of Gerald, the sixteenth earl in the reign of Elizabeth [CORK], caused the final suppression of their authority and confiscation of their estates. The English knights and gentlemen who had grants from the queen of the forfeited lands in the county were—Sir William Herbert, Knt., 13,276 acres; Charles Herbert, Esq., 3768 acres; Sir Valentine Brown, Knt., 6560 acres; Sir Edward Denny, Knt., 6000 acres; Captain Conway, 5260 acres; John Chapman, Esq., 1434 acres; and John Holly, Esq., 4422 acres.

On the breaking out of the rebellion of 1641, the native Irish again took arms, and laid siege to the castle of Tralee, to which a great number of English families had fled. After a siege of six months the place surrendered, and the Irish remained in possession of the country till 1652, when Ludlow, with an army of 4000 foot and 200 horse, again reduced them. Extensive confiscations of the estates of the native Irish followed. Among the new proprietors was Sir William Petty, who obtained a large grant of lands in the neighbourhood of Kenmare, and commenced the smelting of iron, which was carried on with vigour while timber lasted. A colony of Protestants was planted by Sir William Petty round the head of Kenmare river, who were attacked by the native Irish in 1688, and compelled to abandon their possessions. A detachment of King William's army, under Brigadier Levison, entered the county in 1691 and finally reduced it. The confiscations consequent on the last rebellion amounted to 90,116 acres, of an estimated total value at that time of 47,483*l.* 12*s.* 9*d.* About 1710 the coast was harassed by French pirates, which led to the erection of a small fort on Valentia Island. The principal proprietors at present are, the Marquis of Lansdowne, in whom the Fitzmaurice and Petty estates centre; Lord Kenmare, the representative of the Brown family; Lord Headly, Lord Ventry, and the Knight of Kerry.

Kerry contains several monuments of a very remote antiquity, of which the most remarkable are the Cyclopean stone fortresses of Cahirconree, Staigue, and Cahir Donnell; and the sepulchral stones with ogham inscriptions in the neighbourhood of Dingle. Stone cells, probably of the sixth and seventh centuries, are still standing on the greater Scellig Island, at Ventry, and at Smerwick. There is a round tower at Rattoo, one in an island in Loch Currane, part of another at Aghadoe, and a fourth formerly stood near the cathedral of Ardfort. There are also the remains of thirteen religious houses and thirty feudal castles.

The county expenses are defrayed by grand jury presentments. The amount in 1835 was 30,951*l.* 4*s.* 7½*d.*, of which 19,672*l.* was for public roads, buildings, institutions, and other general county charges, and 11,279*l.* 4*s.* 7*d.* for roads charged specially to the several baronies.

KEUPER, in geology, the German term for the upper portion of the new red sandstone formation. It is supposed by some geologists that certain sandstones in Warwickshire, Worcestershire, and other parts of England, correspond to this group of strata. Remains of reptiles are said to have been found in it near Warwick.

KEVEL. [ANTELOPE, vol. ii., p. 83.]

KEW. [SURREY.]

KEY, in music, is the particular diatonic scale, whether major or minor, in which a composition begins and ends, and which more or less prevails in a given piece of music.

The diatonic scale may commence on any note, and that chosen—called the *Key-Note*—governs the progression of the other notes. [SCALE. DIATONIC.] If a composition begins and ends in a scale in which neither sharps nor flats are used, it is in the key of C, the distinctive term *natural* being understood. When three flats are placed at the clef, and the last and lowest note in the piece is E♭, the key is E♭. If in such case the last and lowest note is C, the key is C minor, &c.

As any note in the diatonic and chromatic scales may be taken as a key-note, it follows that there are twelve keys in the major mode, and twelve in the minor; for each scale may have either a major or a minor 3rd. [MAJOR. MINOR.] Hence arise twenty-four keys. But as three major and consequently three minor keys are binominous, there are in name thirty different keys, and as many signatures are in actual use [SIGNATURE]; though, in fact, there is only the before-mentioned number of keys differing in reality.

TABLE OF MAJOR KEYS.

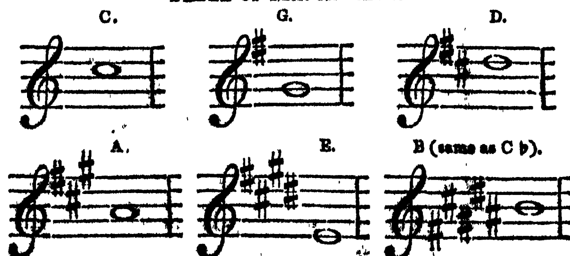

Table of Minor Keys.

By admitting double sharps and flats, the number of keys may be much farther, but not usefully, extended.

KHALIF. [Caliph.]

KHAIR EDDIN. [Barbarossa, Khair Eddin.]

KHAN, a word of Mongol or Turkish extraction, said to mean 'great and powerful lord,' was employed by the nations of central Asia to express the full extent of royal power. This title was assumed by Gengis when he became supreme ruler of the Mongols and Tartars, and was adopted by all his successors. The earlier monarchs of the Ottoman empire were also distinguished by this title. The word is used in Persia in a much more restricted sense, and is applied to the governors of provinces, and to all officers of a certain rank.

The original form of this word was *Khaghan;* Gengis Khan is always called Jinggis Khaghan in the Mongol language. (*Geschichte der Ost-Mongolen*, by Schmidt, Petersb., 1829.)

KHAYA, a genus of plants of the natural family of Cedrelaceæ, which is often made a tribe of the Meliaceæ. Khaya contains only a single species, *K. Senegalensis*, which has been well figured in the 'Flore de Senegambie,' i. t., 32. It forms one of the largest and handsomest of the trees which are found along the banks of the Gambia and in the valleys near Cape Verd. It attains a height of from 80 to 100 feet, and is also one of the most common of the trees of the forest, being called *Cail* by the negroes, and *Cail-cedra* by Europeans. The wood is of fine quality, reddish coloured like the mahogany, which belongs to the same natural family. The bark is remarkable for its bitterness and febrifuge properties, and is taken by the negroes in the form of infusion and decoction, as a cure for the fevers so prevalent in their country.

KHEMNITZER, IVAN IVANOVITCH, an admired Russian fabulist, was born in 1774, at St. Petersburg, where his father, who was a native of Saxony, held the appointment of physician at one of the hospitals. His aversion to medical and anatomical studies determined him to enter the army in preference to following the profession chosen for him; but after serving in two campaigns against the Prussians and Turks, he determined to serve in the army only as a military engineer, in which capacity he quickly won the regard of his superiors. In 1784 he was appointed consul-general at Smyrna, but had hardly arrived there when he died (March 20). Although his Fables reached a second edition in his lifetime, they did not attract much notice until a complete edition of all his pieces appeared in three volumes in 1799, with a memoir of the author and his name, which last had not been previously given to the public. Since then they have been reprinted several times, and have acquired very great popularity.

KHERASKOV, MICHAEL MATVIEVITCH, born October 25, 1733, was a Russian poet of considerable celebrity in the last century, although his reputation has since declined. His epic poem in twelve cantos, entitled the 'Rossiada,' which first appeared in 1785, celebrates the liberation of Russia from the yoke of the Tartars in the reign of Ivan Vassilievitch. Although hardly rising to the dignity of an epic, this production possesses much interest of narrative, and several very striking scenes and descriptions. 'Vladimir,' his second poem of the same class, is in eighteen cantos, and was first published in 1786. Besides these he wrote numerous other works, both in prose and verse, including an imitation of Corneille's 'Cid,' and some other tragedies and dramatic pieces. He died September 27, 1807, aged 74.

KHERSON (*Cherson*, or *Nikolajeff*), a government of European Russia, lies between 46° 12′ and 49° 4′ N. lat., and 29° 10′ and 35° 5′ E. long. It is bounded on the north-west by Podolia, on the north by Kieff, on the north-east by Pultawa, on the east by Ekaterinoslaf, on the south-east by Taurida, on the south by the Black Sea, and on the west by Bessarabia. Its area, according to Hassel and Schubert (1835), is 25,347 square miles, others make it only 19,000; but Hörschelmann (1833) makes it 34,964 square miles.

Its extreme length from east to west is about 250 miles, and its breadth from north to south about 100 miles for one-third of the length from west to east, and for the other two-thirds almost 180 miles. The province, which consists of an immense plain, lies between the Dnieper and the Dniester. A branch of the Dnieper range traverses it for a short distance on the north-east, and on the south-west a small chain belonging to the outskirts of the Carpathians runs into the country from Podolia. It is only on the north-west and north-east borders that there is some wood, and in the neighbourhood of Elizabethgrad there are considerable forests. The rest of the country is a steppe, beginning at Mirgorod and extending across the whole province, where scarcely a tree is to be seen; the soil is however covered with a luxuriant vegetation of grasses and other plants. From February to May the grass grows to such a height that the sheep are quite lost in it. During the great heat the grass gradually withers, and vegetation does not revive till the autumn. In the interior the soil is a grey clay mixed with sand, which is not very well adapted to agriculture, but produces the richest pastures. Here and there are heaths, and in the lower parts swamps: on the coast there is a red ferruginous earth, which produces little besides saline plants.

The Black Sea washes the south of the province from the Dniester to the Dnieper. The principal rivers are the Dnieper and the Dniester, of which the latter forms the boundary between Kherson and Bessarabia. The course of the rivers in the whole province is exceedingly slow, and their water bad. There are very few wells of fresh water; as, for instance, in the whole of the great steppe of Oczakow, 8600 square miles in extent, there are only about a hundred springs of sweet water. The climate is very variable; in summer the heat is from 85° to 90° of Fahrenheit. A dark yellow sky, a wind which raises the dust in clouds, and an immense torrent of rain, are the usual precursors of a thunder-storm, which is awful beyond conception. The nights are always cool. The winter is very cold: most of the rivers freeze over, though but for a short time, and not always so much as to bear a man.

The ground, when by great labour it is cleared of the roots of the grass, and when the saltpetre, which generally appears when the surface is bare of vegetation, is got rid of, will pro-

duce from ten to twenty fold, even without manure, if after being cropped for five or six years it is suffered to lie fallow for an equal time. But the inhabitants dislike agriculture, and prefer the breeding of cattle, so that they never raise corn enough for their own consumption. Almost every two years swarms of locusts desolate the country, but they seldom come farther than Kherson, about seventy miles up the Dnieper. Hemp and flax are grown only for domestic consumption. Tobacco (some of the best in the empire), mustard, and saffron are articles of commerce. There are several varieties of the vine, and the wine has been much improved of late years. Horticulture is much more attended to than agriculture. The forests, as we have said, are confined to the north of the province, and to the vicinity of Elizabethgrad; the latter for a long time furnished almost all the timber required for building the Black Sea fleet, but they are now greatly thinned. The banks of the rivers, especially of the Dnieper, are covered with strong reeds, which are used both for thatch and for fuel. For want of wood, hardly any habitations are seen but thatched clay huts; many of the inhabitants dig for themselves habitations in the earth, choosing particularly the antient tumuli, with which the plain is covered. Of tame animals the most common is the sheep. The wool of the native breed is rather coarse, but of late years great numbers of Merinos have been imported, and there is no other province that has so many sheep of the improved breed. The three provinces of Ekaterinoslaf, Taurida, and Kherson have now 500,000 Merinos. Oxen and buffaloes are numerous, and used for draught; the horses (of which many are wild) are slight, but very spirited and swift-footed. Wild animals of all kinds abound, especially wolves and wild-cats, which last are formidable beasts of prey. The fields are covered with bustards, grey partridges, ortolans, snipes, &c. Besides locusts, the country is infested by large rats, which come from Taurida. There are great numbers of water and other snakes, scolopendræ, whose bite is as venomous as that of the Tarantula, incredible numbers of lizards, and swarms of gnats. The fisheries on the sea-coast and in rivers are very important. The minerals are, fine potter's clay, freestone, slate, chalk, talc, saltpetre, agates, and garnets. The manufactures are of little importance; some, however have been introduced into Kherson and Odessa. The province is most happily situated for trade. The foreign commerce of the country, which is very important and rapidly increasing, will be best described under Odessa, which, though founded only in 1796 by the Duke of Richelieu, is now the staple place for the commerce of all Southern Russia. [Odessa.]

The inhabitants, who are estimated at 607,000, consist of Great and Little Russians (among the latter are many Cossacks), Poles, Moldavians, Rascians, Bulgarians, Tartars, Greeks, Armenians, and Jews, all settled; even the Cossacks of the Bug have renounced their nomadic life, follow agriculture, and have fixed habitations. There are in this government 35,000 foreign colonists, chiefly German, in fifty-six colonies, possessing (in 1836) 284,942 dessatines (60,000 acres) of land. There are also a great many gypsies. The Greek Christians are under the archbishop of Ekaterinoslaf, Kherson, and Taurida, who resides at Ekaterinoslaf, where his cathedral is. In Kherson he has 367 parishes. [Cherson.]

KHORASSIN. [Persia.]

KHOSRU I., called Chosroes by the Greek writers, but most commonly known in the East by the name of Nushirwan, 'noble soul,' succeeded his father Kobad in the kingdom of Persia, A.D. 531. Kobad at the time of his death was engaged in a war with Justinian, the emperor of Constantinople; but Khosru, shortly after his accession, concluded a peace with Justinian, on the payment by the latter of 10,000 pounds of gold. Khosru diligently employed this interval of rest in regulating the internal affairs of his kingdom; the corrupt officers and magistrates, who had been appointed during the reign of his father, were removed; justice was impartially administered in every part of the empire; and the fanatical followers of Mazdak, who had obtained numerous proselytes to the inviting doctrine of a community of goods and women, were banished from his dominions. He divided the empire into the four great provinces of Assyria, Media, Persia, and Bactriana, and established a vizir over each; and he secured at the same time the stability of his throne by the murder of his two elder brothers. In the course of a few years he extended his dominions as far as the Indus, and compelled the nomadic hordes, who had taken possession of the northern provinces of the empire during the reign of his father, to repass the Oxus and withdraw to the central plains of Asia.

Though Khosru was successful in his wars with the people of Asia, he beheld with concern the conquests of Belisarius in Italy and Africa; and afraid lest Justinian should acquire sufficient power to attack the Persian dominions, he collected a large army, and, in violation of the truce that still subsisted, he invaded Syria in 540. His unexpected attack had given the Greeks no time for defence; the principal cities were plundered by the Persian troops, and Antioch, the capital, was taken after a short but vigorous resistance. On his return, Khosru founded, at one day's journey from Ctesiphon, a city, which he called Antioch Khosru, where he placed the numerous captives he had taken in his invasion of Syria. In the following year Belisarius was recalled to defend the East; and his superior military skill enabled him, with an army far inferior to the Persians both in discipline and numbers, to prevent Khosru from extending his conquests. In 542 Belisarius was recalled to Constantinople, and degraded from all his employments; and the generals who succeeded him were easily defeated by the Persian troops. The war continued to be carried on for many years, though with little vigour on either side, in the neighbourhood of the Black Sea, and principally in the territories of the Lagi, a Colchian people; till at length, after much delay and many negotiations, Khosru condescended to grant a peace to Justinian in 562, on the annual payment by the latter of 30,000 pieces of gold.

This peace however was only preserved for ten years. The lieutenants of Khosru had subdued the province of Yemen in Arabia, and compelled the Abyssinians, who had possessed the supreme authority for many years, to withdraw from the country. The Abyssinians were the allies of the emperors of Constantinople; and Justin, who had succeeded Justinian, having entered into an alliance with the Turks, collected a powerful army in order to avenge the cause of his allies. But his efforts were unsuccessful; his troops were everywhere defeated, and the province of Syria was again plundered by the Persian soldiers. Justin was obliged to resign the sovereignty, and his successor Tiberius obtained a truce of three years, which time was diligently employed by Tiberius in collecting an immense army from all parts of the empire. The command was given to Justinian; and a desperate battle was fought between the Greeks and Persians in the neighbourhood of Melitene, a town in the eastern part of Cappadocia, in which Khosru was completely defeated. He died in the spring of the following year, A.D. 579, after a reign of 48 years, and was succeeded by his son Hormisdas IV.

The virtues, and more particularly the justice, of this monarch form to the present day a favourite topic of Eastern panegyric; and the glories and happiness of his reign are frequently extolled by poets as the golden age of the Persian sovereignty. His reign forms an important epoch in the history of science and literature: he founded colleges and libraries in the principal towns of his dominions, and encouraged the translation of the most celebrated Greek and Sanskrit works into the Persian language. A physician at his court, of the name of Barzûyeh, is said to have brought into Persia a Pehlvi translation of those celebrated fables which are known under the name of Bidpai or Pilpay [Bidpai]; and it was from this translation of the Indian tales that these fables found their way to nearly every other nation of Western Asia and Europe. The conquests of Khosru were great and numerous; his empire extended from the shores of the Red Sea to the Indus; and the monarchs of India, China, and Tibet are represented by Oriental historians as sending ambassadors to his court with valuable presents to solicit his friendship and alliance. (See the original passage in Ewald's *Zeitschrift für die Kunde des Morgenlandes*, vol. i., p. 185.)

KHOSRU II., the grandson of Khosru I., was elevated to the throne of Persia, A.D. 590, on the deposition of his father Hormisdas by Bindoes, a noble of the royal blood. In the first year of his reign Khosru was obliged to leave his native country to escape from the treachery of Bahram, who rebelled against his sovereign and seized upon the royal power. Khosru took refuge in the dominions of Maurice, the emperor of Constantinople, who assisted the Persian monarch with a numerous army, with which he was

enabled to defeat Bahram, and again to obtain possession of the sovereignty. The friendship of Maurice was however purchased by the surrender of some of the most important towns of Mesopotamia and the payment of a large sum of money. During the life of Maurice, peace was preserved between the two nations; but on his assassination by Phocas in 602, Khosru took up arms to revenge the death of his benefactor, and in the space of fourteen years subdued almost all the provinces of the Greek empire. In 611 Antioch was taken; in the following year Cæsarea, the capital of Cappadocia, fell into the hands of the Persians; in 614 the whole of Palestine was subdued; in 616 Egypt was conquered, and Alexandria taken by Khosru himself; while another Persian army subdued the whole of Asia Minor, and advanced as far as the Bosporus. The Roman empire was on the brink of ruin; the capture of Alexandria had deprived the inhabitants of Constantinople of their usual supply of corn; the northern barbarians ravaged the European provinces; while the powerful Persian army on the Bosporus was making preparations for the siege of the imperial city. Peace was earnestly solicited by Heraclius, who had succeeded Phocas in 610, but without success. Khosru however did not cross the Bosporus, and at length, in 621, he dictated the terms of an ignominious peace to the emperor. But Heraclius, who had hitherto made very few efforts for the defence of his dominions, rejected these terms; and in a series of brilliant campaigns (A.D. 622—627) recovered all the provinces he had lost, repeatedly defeated the Persian monarch, and advanced in his victorious career as far as the Tigris. Khosru was murdered in the spring of the following year, 628, by his son Siroes.

KIACHTA is a place in Siberia, in the government of Irkutsk, 50° 20′ N. lat. and 121° 40′ E. long., south of the lake of Baikal, and in a sterile country, 2480 feet above the level of the sea, on a small stream also called the Kiachta. A considerable trade is carried on here, as it is the only place in which, according to agreement, the subjects of the empires of China and of Russia are permitted to exchange their merchandise. Kiachta consists of two separate parts; the fortress, called Troitsko Sawsk, where the custom-house, the imperial offices, and the military government are established, and the lower town, or Kiachta, which is nearly two miles farther south, and where the merchants live. Kiachta has one bridge, a square, one wooden church, two chapels, and thirty-seven houses, mostly belonging to merchants, elegantly built, and kept in good order. There are only 321 inhabitants (200 men, 121 women). Troitsko Sawsk contains 4541 inhabitants (2237 males, 2304 females); 648 houses, three churches, two chapels, two parish schools, attended by 105 scholars, and the Russo-Mongol School, supported at the expense of the Buriat Cossacks. Merchants from all parts of Russia have settled here—from Moscow, Kursk, Kasan, Vologda, Kaluga, Nishnei Novgorod, Tobolsk, and Irkutsk.

The commerce of this place with Maimaitchin, the Chinese emporium, which is less than a mile from the lower town, has only risen to importance in modern times. From 1727 it was conducted on account of the Russian government, and was of little importance; but in the last-mentioned year the trade was laid open to private merchants. At first it increased very slowly. In 1806 Klaproth estimated the value of all the goods sold by the Russian merchants at only eight millions of francs, or about 350,000*l.* But in 1821 Cochrane found that the profit of the merchants was equal to the value of the goods sold in 1806. The Russians bring to Kiachta furs, particularly those of the sable, black fox, and ermine; hides, woollen cloth, and other coarse woollen fabrics; glass, looking-glasses, and cattle. They receive in return from the Chinese, manufactured silks and cottons, tobacco, china, furniture, and several kinds of toys; but the principal commodity taken in exchange is tea. Cochrane estimated the quantity of tea imported in 1821 at three millions of pounds weight; and at the great fair of Nishnei Novgorod the value of the tea which was sold in 1823 amounted to twelve millions of paper roubles. The tea brought to the fair of Nishnei Novgorod in 1838 was 37,356 chests, being 5700 more than in 1837: the value was 17,399,500 roubles; to which must be added 560,000 roubles for the value of 5000 chests of tea pressed into cakes. Chinese silks and nankeen were brought only to the amount of 32,000 roubles. The value of the rouble is 10¼*d.*. The merchants of Kiachta and Maimaitchin live on a very friendly footing, and frequently meet in social parties, but only during the day; for no sooner has the tattoo beaten in Kiachta, and the fire-ball ascended from the residence of the *Sargatshei*, or governor, in Maimaitchin, than the gates of the towns are shut, and all communication between them is interrupted.

KIDDERMINSTER, a corporate town and parliamentary borough, in the hundred of Halfshire and county of Worcester. It is situated on the Stour, near the confluence of that river with the Severn; 124 miles north-west by north from London. According to Nash (*Hist. of Worcestershire*) the name of this place was antiently written *Chiderminster*, a term which has reference to the church on the brow of a hill and the water running beneath. At the time of the Conquest it was the king's property, and it remained with the crown until the reign of Henry II., who gave the manor to Manser, his favourite. At a subsequent period it became the property of Waller, the poet, by whom it was sold in 1643-4 in order to pay his fine to parliament on account of what was called Waller's plot. Kidderminster returned members to parliament as early as the 28 Edward I., but owing to disuse the privilege was afterwards lost. By the Reform Act it was again erected into a parliamentary borough, and now returns one member. The earliest charter of incorporation is that of 12 Charles I., but as it conferred upon the corporate body no power to acquire landed property, or to augment the number of magistrates, which was limited to two, they obtained from the crown in 1828 a new charter, which is now the governing charter, and bears date 7th August, 8 Geo. IV. The council consists of a mayor, six alderman, and eighteen councillors.

The town is well lighted, watched, and paved under the superintendence of commissioners appointed by a local act, and the expense is defrayed by a rate. The annual value of the real property of the borough in 1815 was estimated at 13,960*l.*; the assessed taxes in 1831 amounted to 1929*l.*, and the parochial assessments for the same year to 4586*l.* The prosperity of the town appears to be gradually increasing; it possesses considerable trade and a large manufacture of carpets. [CARPETS.] The church is a handsome Gothic structure surmounted by a fine tower: the interior contains many altar-tombs, brasses, and other antient monuments, for a particular description of which we refer the reader to Nash's *History of Worcestershire*, London, 1782, fol., ii., 48. The living is a vicarage in the patronage of Lord Foley, and has an average net income of 1107*l.* At the east end of the church is a Gothic chapel which was formerly, and we believe still is, appropriated to the use of the free grammar-school. This charity was founded prior to the charter of Charles I. The rental of the estates belonging to the school amounts to 491*l.* 19*s.* 1*d.* per annum, in addition to which there are two houses for the use of the upper and lower masters, erected in 1805 at an expense of 1800*l.* The school is divided into an upper and lower school, and the practice now is to take all boys who wish to learn Latin into the upper school. In the lower school the boys are instructed in reading, writing, and accounts, but not Latin. The salary of the upper master is 290*l.* and that of the under master 145*l.* per annum. Notwithstanding the ample endowment of this foundation, it has hitherto been of comparatively little advantage to the town. In 1835 there were but six boys in the upper school, and the average number that attended the lower school was only fifteen. Besides the free school there are several almshouses and other benevolent institutions. The population of the town in 1831 was 14,981, having been augmented by 4272 persons during the 20 years preceding, which is to be ascribed chiefly to the flourishing state of the manufactures during that period. The population of the parish is 20,865.

(Nash's *History of Worcestershire;* Carlisle's *Grammar Schools;* *Corporation Reports*, &c.)

KIDNAPPING is defined to be the stealing or conveying away of a man, woman, or child, and is an offence at common law, punishable by fine and imprisonment, and until the abolition of that mode of punishment by 1 Vict., c 23, by pillory The 9 Geo. IV., c. 21, which is directed

against child-stealing, enacts that if any person shall maliciously, by force or fraud, lead, or take away, or decoy or entice away, or detain, a child under the age of ten years, with intent to deprive its parents, or any other person having the lawful care of such child, of the possession of it, or with intent to steal any article upon or about the person of such child, to whomsoever such article may belong, or shall receive and harbour with any such intent as aforesaid any such child, knowing that it has been by force or fraud led, taken, decoyed, enticed away, or detained, every such offender, and their counsellors, procurers, aiders, and abettors, shall be guilty of felony, and shall be liable to be transported for seven years, or to be imprisoned, with or without hard labour, in the common gaol or house of correction, for any time not exceeding two years; and if a male, to be once, twice, or thrice publicly or privately whipped (if the court shall so think fit) in addition to such imprisonment.

The act does not extend to a person who shall have claimed to be the father of an illegitimate child, or to have any right to the possession of such a child, on account of his getting possession of such child, or taking it out of the possession of the child's mother or other person who has the lawful charge of it.

KIDNEYS are two glands lying in the lumbar region, on each side of the spinal column. They are composed of numberless and delicate tubular ramifications, on whose walls there is a fine network of capillary arteries and veins, and which are all collected into one mass of a firm fleshy consistence, enclosed in a fibrous capsule.

The ureter, through which the urine secreted by the kidney is conveyed to the bladder, dilates at its extremity into a wide pouch, the pelvis of the kidney, which is divided into several portions called calyces. Into each calyx a nipple-like process, or papilla, projects, at whose extremity there are several minute orifices, each opening into a very fine canal, which, as it is continued into the substance of the kidney, ramifies and becomes tortuous. On all these canals, or tubuli uriniferi, minute blood-vessels ramify, and secrete the urine, which is conveyed from the tubuli into the calyces, and from them through the pelvis and the ureter into the bladder.

The papillæ, and the conical bodies called pyramids, of which they are the extremities, being chiefly composed of the excretory canals, are nearly white, and of a firm dense structure; but as the tubuli ramify, their branches separate in a somewhat radiating manner, and the blood-vessels filling the intermediate spaces between them give to all the exterior part of the kidneys a deep red colour, and a softer and more fleshy consistence. Hence the kidney is generally described as divided into a cortical, or vascular, and a medullary or tubular portion.

The general structure of the kidney may be best shown by making a section from its convex border into the pelvis. The surface of each part then presents several whiteish conical bodies, the pyramids, whose rounded apices, the papillæ, project into corresponding tubular calyces, and whose bases are surrounded by the vascular cortical substance. In the latter no distinct arrangement of vessels can be seen, but there are scattered irregularly through it minute granular bodies called the acini, or corpuscles of Malpighi, which are composed of delicate tortuous arteries.

In the early embryo of mammalia each papilla, with the tubules opening on it and its blood-vessels, forms a separate body; but during growth the several renculi are united into one mass, their original separation being however indicated by the more or less deeply lobulated form of the organ in various animals, and occasionally in man.

KIDNEYS, DISEASES OF. The principal disease to which the kidneys are liable is that which gives rise to the formation of calculi. [CALCULUS, *Renal*.] Sometimes the stone is retained in the pelvis of the kidney, where, by continued depositions, it may increase till it completely fills the pelvis and calyces; but more frequently it passes through the ureters into the bladder, producing in its passage violent spasmodic pain in the loins, sickness and nausea, hæmorrhage, &c. This affection is the most common cause of inflammation of the kidneys (nephritis), from which abscess and other morbid alterations may result. Chronic inflammation seems to be the most frequent cause of a peculiar alteration in the structure of the kidneys particularly described by Dr. Bright ('Medical Reports'), of which the chief characters are, the interstitial deposition of a pale yellowish and firm substance, and a granular or tuberculated form of the surface of the kidney, with a great decrease of its vascularity. This condition is very common in hard drinkers; it usually produces dropsy, and is indicated by a dull heavy pain in the loins, a bloated expression of the countenance, a hard pulse, and the secretion of so large a quantity of albumen with the urine that it coagulates on being heated, or on the addition of a little bichloride of mercury.

Suppression of urine may be the ultimate result of obstruction from caculi in the ureters, or it may occur as an idiopathic disease. It is a condition of great danger, for low delirium and a comatose sleepy state very often supervene on it, and soon terminate fatally. Long and often repeated attacks of retention of urine from obstruction produce dilatation of the ureters and pelvis, which sometimes acquire an enormous size. There may result from the same cause a gradual absorption of the substance of the kidney, till in an advanced stage there is found nothing but a thin sac containing urine in a single cavity, or in a number of separate pouches. The kidneys are also subject, in common with other organs, to the deposition of various morbid substances, as cancer, fungus, hæmatodes, melanosis, tubercle, &c. But the diagnosis of all the chronic affections of this organ is extremely obscure, the principal indications of each being the same, viz. the dull heavy pain in the loins, dropsy, and sometimes hæmaturia.

KIEL, the capital of the duchy of Holstein, is situated in a beautiful part of the country, and on a bay of the Baltic, called the Kielerfiord, which forms an excellent harbour, and admits even large ships of war to anchor near the town: 54° 10′ N. lat., 10° 8′ E. long. It is surrounded with walls, in which there are five gates; and is pretty regularly built, with straight well-paved streets The university of Kiel was founded in 1665, by Christian Albert, duke of Holstein. Though the university has a library of 70,000 volumes, a revenue of 20,000 dollars, 19 regular and 10 extraordinary professors, and all the necessary appendages, the number of students is small, which is probably owing to the circumstance that living is very dear. The number has however increased of late years. The published annual accounts state that in 1818 there were 107 students, in 1825 about 390, in 1831 about 311, and in 1836 only 252, which is probably near the present amount. The inhabitants, amounting in 1837 to 11,791, including those of th village of Brunswyck, have some manufactures of linen hats, tobacco, sugar, &c., and some business in ship building. Their trade in corn, dried herrings, and sprats (which are celebrated) is considerable, and has much increased since the completion of the Holstein or Kiel Canal, which joins the Baltic and the German Ocean. [HOLSTEIN.] The most busy time of the year is at the annual fair on the three days after twelfth-day, which is attended not only by the farmers and the merchants, but by the nobility and gentry of Sleswick and Holstein. Near Kiel there is an antient castle delightfully situated, but not inhabited. It is now fitting up for the residence of the prince of Holstein Glücksburg, who has married the Princess Wilhelmina, daughter of the king of Denmark, on her divorce from her first husband, Prince Frederick. There is a small congregation of Christians of the Greek religion at Kiel. There is also an establishment for sea-bathing, and steam-boats ply regularly between Kiel and Copenhagen.

KIEN LOONG, son of the emperor Yung Tching, and grandson of Kang He, succeeded his father on the throne of China in 1735, being then twenty-six years of age. The principal events of his long reign are: 1. The war which he carried on, from 1753 to 1759, against the Olots or Eleuts, the Kashgars, and other Tartar nations of central Asia, who, under the descendants of Galdan, or Contaïsh, the Tartar chief, who was subdued by the arms of Kang He in 1696, had again revolted. Kien Loong defeated them, and again established the Chinese supremacy over central Tartary, north-west of China, as far as Kashgar. In consequence of these successes a great triumph took place at Pekin, in April, 1760, on the return of the victorious army. 2. In 1770 the Turguts, a Mongolian tribe, dissatisfied with the Russian government, having removed from the banks of the Volga, after crossing the steppes of the

Kirghis and other tribes, came to place themselves under the protection of China, when Kien Loong, rejoicing at this event, gave them a part of the country of the expelled Eleuts. (Amiot, *Mémoires concernant les Chinois.*) 3. In 1773 Kien Loong attacked and conquered the Miao-tse, a race of mountaineers on the borders of the province of Koei-cheow, north-west of Canton, who had never been subdued before. By the Chinese accounts great barbarities were committed by the conquerors, and the tribe was said to be nearly exterminated; but yet we find this same tribe rising again in great numbers so late as 1832, and giving full employment to two Chinese armies commanded by the viceroys of Canton and of Hoonan. However, Kien Loong commemorated his victory over the Miao-tse by paintings, which were copied and sent to France to be engraved. 4. About the years 1790-91, the rajah of Nepaul having invaded Tibet, a Chinese army was sent against him, which obliged him to withdraw to his own dominions, and the country of Lassa or Tibet was placed under the protection of China. (Staunton's *Narrative of Lord Macartney's Embassy*, vol. ii., ch. 1.)

Among the remarkable circumstances of Kien Loong's reign may be mentioned his edict of 1753, forbidding the exercise of the Christian religion under severe penalties, in consequence of which a kind of persecution against the Christian converts took place in several of the provinces. The Jesuit missionaries at Pekin however, as men of science, continued to enjoy the favour of the emperor, who was himself fond of learning, and a poet. [AMIOT, LE PERE.] He collected an immense library of all the most interesting Chinese works, and caused a geography of China to be compiled, as well as a Chinese and Mantcheou dictionary. Another remarkable occurrence of his reign is his reception of the British embassy in 1793, the particulars of which, upon the whole, reflect credit upon the character and intellect of Kien Loong.

In February, 1796, Kien Loong, having completed the sixtieth year of his reign, abdicated in favour of his son Kea King, a very inferior man to his father. Kien Loong died in February, 1799.

KIEW (written also Kieff, Kiev, Kiow) is a government of that part of Russia in Europe which is called Little Russia, and lies between 48° 30′ and 51° 50′ N. lat., and 28° 40′ and 33° 25′ E. long. It has an area of 20,540 square miles, or somewhat more than one-third of that of England and Wales. It borders on the governments of Minsk, Tchernigow, Poltava, Kherson, Podolia, and Volhynia. The surface of the country is undulating; the hills and high lands, which follow the course of the rivers, do not in any part attain a considerable elevation. There are many pleasing rural views, but no grand or striking natural scenery; and in general there is the sameness that is usual in flat countries. The Dnieper range of hills can only be considered as the last ramification of the Carpathians, which it joins in Podolia: in the circle of Tschigri a branch of it quits the river, and traverses the whole southern part of the province in a north-western direction. The land to the north of this branch has an extremely rich and fertile soil. On the south the soil is poorer, more sandy, and like a steppe; but still there are tracts of luxuriant corn-fields and good pastures. The chief, and in fact the only navigable river is the Dnieper, which however is a frontier river, forming the entire north-eastern boundary between this province and Tchernigow and Poltava for nearly 250 miles. It is from 600 to 1200 feet wide, flows with rapidity, has hard, muddy water, and here and there blocks of stone and eddies, which however do not obstruct the navigation in this province. The chief rivers that flow into it are: 1. The Pripetz, which comes from Minsk, and is here joined by the Ush or Usza from Volhynia; 2. The Teterew, from Volhynia, which receives several streams before it falls into the Dnieper; 3. The Irpen; 4. The Stugena; 5. The Ross, which rises in the west of the province, divides into two arms, and forms a large island; and 6. The Tiasmin, which comes from Kherson. There are no lakes of any consequence in the whole province: most of the small lakes are in the southern part. The climate is extremely mild and dry, and adapted to all the productions of the temperate zone, though no vines are cultivated. The rivers freeze in December, and thaw in February; but there are some winters (though they are rare) when there is very little snow and ice: the north wind however is always severely felt. The heat in summer is often so great that the rivers are dried up. Rain seldom falls in summer. Locusts are common, and the migratory locust often does great injury.

Agriculture is the chief employment of the inhabitants. The fruitful soil produces all kinds of corn, pulse, hemp, flax, and tobacco. The millet is of a peculiar kind, bearing several ears on one stem; the grain is large, round, and of excellent quality. The gardens produce all kinds of vegetables, and likewise melons, water-melons, and various kinds of fruit. Fruit of all kind prospers, except the vine. The country-people however do not grow much fruit, but are content with their wild wood-berries.

Kiew has more and better timber than any other province of Little Russia. Next to agriculture the breeding of cattle is the chief occupation of the inhabitants. The oxen are large and of a good breed, generally of a grey colour Great numbers are fattened and sent to Austria, Germany, and the interior of Russia. The horses are small, but have many good qualities, and are very fit for light cavalry. Few sheep are kept, but great numbers of swine. In the forests there are foxes, a few wolves, fewer bears, but many deer; there are hares, partridges, quails, and ortolans. In the Dnieper there are beavers and otters, but they are rare, and in that and the other streams there are many kinds of river fish, though not sufficient for the consumption of the people. The only minerals made use of are clay, lime, chalk, stone for millstones, and bog-iron. The manufactories are unimportant; they are confined to the towns, and furnish very little for exportation. The trade consists in the exportation of the produce of the province, and the importation of salt, metal, wine, manufactured goods, and colonial produce. The population is 1,530,000. The villages are much closer together than in Great Russia, and have a very cheerful and pleasing appearance; and all the houses have gardens, in which there are at least cherry and plum trees. The houses in the country are made of brushwood and branches of trees, covered with clay within and without, all whitewashed and thatched, and kept very clean, all the rooms being regularly washed twice a week. The inhabitants are chiefly Little Russians; they are a more poetical people than the Great Russians, are passionately fond of music, and always sing at their work. The subjects of their songs are the beauties of nature, love, and brandy. In general the Little Russian sings, plays, and dances whenever he can; his dances are full of voluptuous attitudes. He is addicted to drinking, though not so much so as other Russians, and has better but very intoxicating beverages. Industry is not one of his virtues, and he only works as much as is necessary for his subsistence and the gratification of his most urgent wants. In the town of Kiew there are many Great Russians and Germans; the Poles are the chief landholders and nobles, and possess almost all the great estates. Jews are everywhere numerous; they have all the public-houses, inns, and shops, and are likewise the butchers, cattle-dealers, &c. Most of the inhabitants are of the Greek church, under the archbishop of Kiew and Galiz, whose diocese, erected in 932, is of the first class, and has under it 1304 parishes. Of the Poles, many are Roman Catholics, and some Calvinists; of the Germans, many are Lutherans. The Jews have their synagogues and rabbis. The nobility are numerous, but few families are very wealthy. In the old province of Kiew the Polish nobility amounted to 42,207 persons, and the government as now constituted probably has as many. The citizens are poor, the Jews being in possession of nearly all trades in the towns; the peasantry are almost all serfs.

KIEW, the capital of the above government, situated in 50° 27′ N. lat. and 30° 27′ 45″ E. long., is built on a hill on the right bank of the Dnieper, which has of late years so much decreased both in width and depth, that the trading barks commonly navigate the narrow channel in the middle of the stream. There is a bridge of boats across the river. The town consists of three parts, each at some wersts distant from the others, viz.: 1, the old fortress Petschersk, with celebrated caverns and catacombs, containing the bodies of 118 saints well preserved. Nestor, the most ancient Russian historian, lived in this convent. 2. Old Kiew, or Sophienstadt, containing the fine cathedral of St. Sophia, and the residence of the archbishop. 3. Podol, containing most of the private houses, 20 churches, an imperial palace, and the townhall. A fourth quarter was built under Catherine II., and called Vladimirstadt; but even in 1821 it was scarcely inhabited, and later writers do not mention it. Besides its cathedral, 25 churches, 9 convents, and a Greek

ecclesiastical academy, Kiew has a university, founded in 1834, called St. Vladimir's university, which has obtained the library and collections of the Volhynian Lyceum at Krzeminiec. Kiew contains the oldest Greek ecclesiastical academy in Russia, which was founded in 1588 and confirmed in 1737: it has 10 professors and above 1000 students. The troubles which agitated the provinces which now compose the district of Kiew had caused the lyceum of Krzeminiec to be transferred to that city. Some time afterwards the emperor resolved to re-organize that institution by placing it on a broader and more solid basis, chiefly with respect to the education of the youth of the governments of Kiew, Podolia, and Volhynia. The lyceum of Kiew has consequently been transformed into a university, to which the name of St. Vladimir's University was given. (Ukases of 8th November and 25th December, 1833.) It is endowed with all the revenues of the lyceum of Krzeminiec, and has the library and all the collections belonging to that institution. In 1836 there were 88 professors and masters, and 203 students. The observatory is well furnished with instruments, and the library consists of above 46,000 volumes. There are considerable manufactories of earthenware, many tanneries, and a very celebrated fair, attended by 30,000 Turks, Armenians, Germans, Swiss, English, &c. The population is about 40,000.

KILDA, ST., the most northern of the Hebrides, is situated in 59° N. lat., and consists of an uneven mountain-ridge, whose most elevated point, called Conochan, rises 1380 feet above the sea-level. Dr. MacCulloch estimates the greatest width of the island at two miles, and its length at three miles; but according to other authorities its length does not exceed two miles. With the exception of some imperfect peat upon the higher points, the whole of the surface is covered with a thick turf of the freshest verdure, and highly susceptible of cultivation, were it not for the westerly winds which limit the agriculture to the south-east declivity, where there is most shelter, and where the village is situated. The tract adjoining the village is held conjointly by the inhabitants, their respective ridges being interchanged every three years. The rest of the island is in pasture, allotted to sheep and black cattle, the average stock of which is estimated at 2000. Although the people dress in the English or Lowland style, and no trace of either kilt or tartan is to be seen, the English language is altogether unknown, and Gaelic is the only one understood. The chief part of their food consists of the flesh and eggs of the sea-birds, among which the gannet, puffin, and fulmar are most in request; and the supply furnished by these birds is so abundant that little or no attention is given to fishing, although large shoals of cod and ling are frequently seen. The down of the fulmar is also much valued; and in 1815 the rent of the island, which averages 40*l.* per annum, was paid wholly in the feathers of that bird. There are three principal springs, the largest of which, Tober-nam-buy, produces a considerable stream. The population in 1824 was distributed among twenty families, and consisted of 110 individuals. (See MacCulloch's 'Highlands,' from which this notice is chiefly drawn.)

KILDARE, an inland county of the province of Leinster, in Ireland; bounded on the north by the county of Meath, on the east by the counties of Dublin and Wicklow, on the south by the county of Carlow, and on the west by the Queen's and King's counties. According to the map published under the superintendence of the Society for the Diffusion of Useful Knowledge, it is situated between 52° 50′ and 53° 25′ N. lat., and between 6° 27′ and 7° 10′ W. long. Its greatest length from north to south is 32 Irish or 40¼ statute miles, and its greatest breadth from east to west is 21 Irish or 26¾ statute miles. According to the above map, it has an area of 381,818 statute acres, or 597 statute square miles. The area is elsewhere estimated at 392,435 statute acres, of which 325,988 are cultivated ground, and 66,447 acres are unprofitable bog and mountain. The population in 1831 was 108,424.

The surface is more flat than that of any other county of Ireland. The only considerable elevations are the hills of Rathcoole, which form the western extremity of the range of the Dublin mountains, and a detached group which occupies part of the southern margin of the Bog of Allen in the central northern division of the county. This group consists of the Red-hill, Dunmurry-hill, Grange-hill, and the Hill of Allen, which last is detached from the others, and terminates the range on the north-east. It is a conical hill nearly insulated by tracts of bog, and rises about 300 feet above the level of the surrounding country, which is here about 260 feet above the level of the sea. An open table-land extends from the southern base of this group to the acclivities of the Wicklow mountains on the south-east, and divides the middle and southern parts of Kildare into two districts, of which the one slopes gradually towards the river Liffey on the east, and the other towards the river Barrow on the west. North from the Dunmurry range the upland district spreads east and west, forming the southern boundary of the basin of the river Boyne on the west, and the western and northern boundary of the valley of the Liffey on the east. It is here overlaid to an extent of 50,000 statute acres by a portion of the vast tract of peat bog called the Bog of Allen. This part of the county is traversed by the Grand and Royal canals in nearly parallel lines from east to west.

The district which slopes towards the Barrow, comprising the western part of the county from the Bog of Allen to the county of Carlow, is divided into three open vales by low ranges of undulating ground extending in parallel directions from the central table-land towards the south-west. The declivity in each of these is very gradual, the channel of the Barrow being not more than 100 feet below the general level of the upland district. The most northern of these vales, included between the summit level of the Bog of Allen on the north and the range of the Dunmurry hills on the south and south-east, is drained by the Feagile and Little Barrow or Rathangan rivers, which, uniting at the lower extremity of the valley, join the Barrow where that river, changing its course from an eastern to a southern direction, becomes the boundary of Kildare. The northern side of the valley is greatly encumbered with bog; the southern side is open and arable. About midway between the source of the Little Barrow and its junction with the Great Barrow is the thriving market-town of Rathangan, through which a branch of the Grand Canal, diverging from the main trunk at the head of the valley, is carried in a direction parallel to the tributary river to join the Barrow Navigation at Athy. The length of this line from Lowtown on the summit level to Athy is 27 miles 7 furlongs. Monasterevan, situated near the junction of the lesser and greater Barrows, also possesses great advantages as a station for carrying on traffic. The Barrow is here crossed by the above canal, which from Monasterevan to Athy is carried along the western bank of the river. From the level at Monasterevan another branch canal is carried westward to the towns of Portarlington and Mountmellick, in the Queen's County, a distance of 11½ miles. The country about Monasterevan on both sides of the river is well improved. Moore Abbey, an antient seat of the Loftus family, and latterly the residence of the Marquis of Drogheda, is situated on the east bank. The present mansion, which is surrounded by a well timbered tract of country, occupies the site of an abbey founded here by St. Abban in the seventh century, and re-edified by O'Dempsy and O'Connor in the twelfth century. Ten miles south from Monasterevan on both banks of the Barrow is Athy, at the junction of the Barrow Navigation with the above-mentioned branch of the Grand Canal. Athy was formerly a place of importance as a frontier town of the English Pale. It had greatly declined prior to the opening of these lines of navigation, but is now the chief point of traffic between Dublin and Carlow. A series of low detached hills, extending from Athy in a north-easterly direction to Old Kilcullen, includes an open tract of country about eight miles square, watered by the river Finnery. The lower part of this district is chiefly occupied by bogs. The town of Kildare, at present a small place, is situated on the elevated tract at the upper end of the vale. It is a town of great antiquity, and still possesses numerous remains of former importance, including the ruins of a cathedral, castle, and several religious houses, with a very high and perfect round tower. The surrounding country is open, and generally under tillage, with the exception of the Curragh of Kildare, a common containing upwards of 3000 Irish acres, which extends six statute miles along the crest of the table-land between the towns of Kildare and Kilcullen. This is a celebrated race-ground; the turf throughout is close and elastic, and the surface smoothly undulating. Old Kilcullen is situated on a hill a mile and a half from the eastern extremity of the Curragh. It was formerly a walled town, and is said to have had seven gates. The erection of a bridge over the Liffey, in 1309, at New

Kilcullen, about two miles to the north, led to its decay; it is now an insignificant place. Southward and eastward from the range of hills extending from Kilcullen to Athy lies a fertile tract watered by the rivers Greece and Leir, which fall into the Barrow at the southern extremity of the county. The upper portion of the valley of the Greece is highly cultivated, and to a great extent in demesne lands. On this river, near its source, is the neat and prosperous village of Ballytore, the principal inhabitants of which are Quakers. Farther south are the villages of Timolin and Moone, the latter on the Greece, near Belan, a seat of the earl of Aldborough. Belan House, at the time of its erection in the beginning of the eighteenth century, was considered the most splendid modern mansion in Ireland. It is however a plain structure which would now rate among residences of the second class. The great southern road from Dublin, passing through Ballytore and Timolin, leads to Castledermot, a tolerably well-built town on the river Leir, near the southern extremity of the county. Prior to the arrival of the English, this was the seat of the O'Tooles, princes of Hy-Mail, a territory extending out of Wicklow into the southern parts of Kildare. During the Anglo-Norman period it was a place of importance in the Pale: there still remain numerous ruins of its ecclesiastical and military buildings, including a round tower in good preservation. The country is here open and under tillage, but bare of timber.

That part of the valley of the Liffey which is included within this county is formed by the western slope of the Dublin mountains on the one side, and by the subsidence of the table-land of Kildare on the other. Naas, the most considerable town in the county, is situated about two miles east from the river, in the centre of the plain included between it and the range of the Dublin mountains. A branch of the Grand Canal is carried from Newbridge to Naas, and thence to Corbally Harbour, within 1½ miles of Kilcullen Bridge. On the great southern road from Dublin to Naas, about a mile north from the latter, is Johnstown, a remarkably neat village in the vicinity of Palmerstown, the residence of Lord Mayo. The country in this neighbourhood is in a high state of cultivation, and much of it in demesne. The western bank of the river particularly, from the point where it enters the county to Leixlip on the Dublin boundary, is almost wholly occupied by a succession of demesne-lands, including numerous residences of the best class. Among these the most remarkable are Killadoon, the seat of the earl of Leitrim, Castletown, that of Colonel Conolly, and on the opposite side of the river, near the line of the Grand Canal, Lyons Castle, the residence of Lord Cloncurry. Celbridge, on the western bank of the Liffey, is a well-built town, and was, until recently, the seat of an extensive woollen manufacture. It is now declining in consequence of the cessation of these works. Leixlip, at the point where the Liffey enters the county of Dublin, is a picturesque village, much visited by pleasure parties from the metropolis. The banks of the Liffey are here steep and well wooded, and the river for a considerable distance runs in a series of rapids. A ledge of rock, about ten feet in height, stretching across the channel, forms a pleasing waterfall, called the Salmon Leap, which is the chief object of attraction. From Celbridge and Leixlip to Maynooth, situated three miles farther westward, the country is to a great extent in demesne. Maynooth, on the Ryewater, a tributary of the Liffey, which runs into the river at Leixlip, was formerly the chief seat of the earls of Kildare, considerable remains of whose castle are still standing. The town is neatly built, consisting of one main street, at the western end of which is the entrance to the Roman Catholic College, flanked by the ruins of the castle. Near the other extremity of the main street is the entrance to Carton, the residence of the duke of Leinster. This demesne is finely timbered: in the arrangement of the plantations regard has been had to the most pleasing combination of autumnal tints. The house consists of a centre of grand proportions connected by colonnades with pavilions, and contains a good collection of pictures and other works of art. The Royal Canal, crossing the Ryewater by an aqueduct a little above Leixlip, passes Maynooth, and so westward by Kilcock, a thriving market-town on the borders of Meath. Westward from Kilcock, the Royal Canal crosses the Blackwater and Boyne rivers by aqueducts within this county. The district traversed by this canal is, for the most part, open and arable, rising southward towards the Bog of Allen, the borders of which in one place approach within a mile of the line of navigation. The Grand Canal, which crosses the Liffey by an aqueduct near Naas, and runs nearly parallel to the Royal Canal across this county, is carried through the above-mentioned bogs at a distance of about ten miles farther south. The tract which it traverses comprises about 40,000 statute acres of peat-moss, in some places 40 feet deep, reposing on limestone gravel, which rises in low cultivable ridges between the principal fields of morass. The Island of Allen is an elevated tract of this kind, surrounded by bog, between the summit level of the canal and the town of Kildare. The summit level is supplied by two lateral branches, one of which, 5 miles in length, extends to Milltown, near Kildare in the south; and the other, 3¾ miles in length, is carried through the bogs of Cushlea to the Blackwood Reservoir on the north. A subsidence of 20 feet in the substance of the bog has been caused in some places by the opening of these extensive drains, and great tracts have been made available for purposes of turbary which were before inaccessible. Large quantities of peat are now cut all along the line, for sale in Dublin. The huts of the turf-cutters are excavated from the banks of the morass and covered with sods, and are the only habitations through successive tracts of several miles. The decayed village of Prosperous is situated near the eastern extremity of this dreary tract. An attempt was made to establish the cotton manufacture here in the latter end of the last century, and much money was expended on buildings; but the enterprise entirely failed.

The north-western part of the county, extending from the Bog of Allen to the Boyne, is open and chiefly in pasture. The towns here are Carberry and Johnston's Bridge.

The great southern and western mail-coach roads pass through Kildare: the former by Naas, where it divides, one branch going by Kilcullen Bridge to Carlow, and another by Newbridge to Maryborough; and the latter by the Meath boundary through Kilcock to Athlone. The remainder of the county is well provided with roads made and kept in repair by grand jury presentments.

The climate, from the quantity of boggy surface exposed, is more moist than that of the neighbouring counties on the north and south. In the central district the air is pure and keen; and milder and more salubrious in the valleys of the Liffey and Greece.

Geology.—The clay-slate, which flanks the granite axis of the Dublin and Wicklow mountains, occupies about one-fourth part of the surface of Kildare. It extends from the extremity of the Rathcoole group in the county of Dublin across the valley of the Liffey, whence it runs in a south-west direction towards Athy, forming the Kilcullen group, and occupies the entire valley of the Greece, with the exception of its lower extremity, where the verge of the limestone plain is interposed between it and the line of the Barrow. The granite tract of Carlow extends into the south-eastern extremity of Kildare as far as Castle Dermot, where the clay-slate passes into mica-slate along the eastern portion of their line of junction. The remainder of the county is occupied with the floetz limestone of the great central plain, broken only by the group of Dunmurry and the Hill of Allen. The Hill of Allen is composed of a mass of granular compact greenstone and greenstone porphyry protruded through the floetz limestone. Large crystals of hornblende and felspar occur throughout the greenstone. Red Hill, Dunmurry Hill, and the western foot of Grange Hill consist of alternating beds of fine-grained grauwacke, grauwacke slate, and clay-slate, with a general dip of 60° towards the south-east, but in some places vertical. A small patch of red sandstone conglomerate occurs on the northern declivity of Red Hill. These strata, which have been quarried for millstones, range east and west, and dip 17° north. Between Dunmurry Hill and Grange Hill, which consists of trap, the floetz limestone is interposed, and again between Grange Hill and the Hill of Allen. At the northern extremity of the Hill of Allen is a slight eminence called the Leap of Allen, composed of red sandstone conglomerate, which is quarried for millstones. Indications of copper have been observed on Dunmurry Hill, but hitherto there have not been any mining operations actually carried on within this county.

Soil and Agriculture.—The soil is generally a rich loam,

resting on limestone or clay-slate. Calcareous gravel, which is found through the greater part of the county, was profusely used as a manure during the last century; but from its exhausting effects on the soil it has been generally discontinued. The opening of the Grand and Royal canals has given facilities for obtaining manure of the best description from Dublin, by means of which the lands of the central and western districts are now in much better heart than they were at the beginning of the present century. The chief tract of pasture-land in this county is the Curragh, which is used as a sheep-walk. There are rich fattening lands in the baronies of Carberry, Clane, and North and South Salt, which occupy the north-western and north-eastern portions of the county. An improved system of agriculture has been introduced by the resident proprietors, and is practised to some extent by the smaller farmers. Oxen are in general use both for draught and the plough. The character of the stock has been much bettered of late years by the introduction of the best English breeds of sheep and black cattle. The late and present duke of Leinster have been mainly instrumental in promoting these improvements. The grain raised in Kildare is generally of prime quality: the quantity sold at the different market-towns in the years 1833 and 1835 appears from the following table:—

	Wheat. (barrels.)		Oats. (barrels.)		Barley. (barrels)		Bere. (barrels.)	
	1833.	1835.	1833.	1835.	1833.	1835.	1833.	1835.
Naas . .	941	750	16,085	12,796	50	50	1412	1125
Kilcock . .	40,000	40,000	12,000	12,000	1000	1000	7000	7000
Athy . .	57,720	37,811	19,472	19,878	8075	5797	..	..
Rathangan .	13,500	14,500	..	..	..	..	..	..
Kildare . .	1,090	1,113	1,152	1,230	380	145	150	388
Robertstown	..	..	3,000	3,000	..	..	..	..

There is no return from Kilcullen, which is also a considerable market for grain. Besides the grain disposed of in market, large quantities are sold by sample at the different mills and corn-stores within the county, or sent by the canals to Dublin. The milling trade is extensively carried on.

The only other manufactures carried on within the county are, a manufacture of cotton, on an extensive scale, lately commenced at Inchyguire, near Ballytore, and a small manufacture of woollens still continued at Celbridge.

The condition of the working-classes is somewhat better than in most of the neighbouring counties. The average rate of wages for agricultural labourers is 10*d.* per day, for about 110 working days in the year. The appearance of the peasantry is generally decent: and they use the English language universally.

Civil Divisions.—Kildare is divided into the baronies of Carberry on the north-west; Ikeathy and Oughterany on the north, containing the town of Kilcock, population (in 1821) 1730; Salt North on the north-east, containing the towns of Maynooth (pop. 2053), Celbridge (p 1647), and Leixlip (pop. 1159); Salt South; Naas North on the east, containing the town of Naas (pop. 3808) and the villages of Sallins (pop. 419) and Johnstown (pop. 101); Naas South; Kilcullen, also on the east, containing the town of Kilcullen Bridge (pop. 699); Narragh and Rheban East, containing the town of Ballytore (pop. 933); Narragh and Rheban West, containing the town of Athy (pop. 4494); Kilkea and Moone on the south, containing the town of Castledermot (pop. 1835), and the village of Moone (pop. 244); Ophaly East, containing the town of Kildare (pop. 1753); Ophaly West, containing the towns of Monasterevan (pop. 1441) and Rathangan (pop 1165); Clane in the northern centre, containing the towns of Clane (pop. 1216) and Prosperous (pop. 1038); and Connell in the southern centre, containing the town of Newbridge (pop. 377) and the village of Robertstown (pop. 281).

Athy is incorporated by charter of 11 James I. The governing body consists of sovereign, bailiffs, and burgesses. The sovereign holds a court having jurisdiction to the amount of 40*s* Irish. The revenue of the corporation is 154*l.* per annum. Naas is incorporated by charter of 11 Elizabeth and 7 James I.; but no court has existed here for several years. The corporation of Kildare, created by charter of Henry VIII., is now extinct; so also is that of Harristown, incorporated by charter of 33 Charles II.

Prior to the Union Kildare was represented in the Irish Parliament by ten members; two for the county, and two members for each of the above corporate towns. It is now represented in the Imperial Parliament by two county members only. In 1836 the county constituency was 1382 The assizes are held alternately at Naas and Athy, in each of which there is a county court-house and gaol. The general quarter-sessions are held at Athy, Maynooth, Kildare, and Naas. The constabulary force in the year 1835 consisted of 1 resident magistrate, 4 chief constables, 40 constables, 205 sub-constables, and 3 horse. The cost of maintaining this force for the year was 9079*l.* 18*s.* 10*d*, of which 4695*l.* 9*s.* 7*d.* was chargeable against the county. The total number of criminals committed to Naas gaol in 1836 was 399, of whom 328 were males and 71 females. Of these 72 males and 5 females could read and write, 92 males and 19 females could read only, 155 males and 44 females could neither read nor write, and of 9 males and 3 females the instruction could not be ascertained. The total number of offenders committed to Athy gaol in the same year was 328, of whom 184 were males and 54 were females. Of these 65 males and 6 females could read and write, 58 males and 5 females could read only, 57 males and 41 females could neither read nor write, and of 4 females and 2 females the instruction could not be ascertained. The district lunatic asylum for Kildare is at Carlow. There is a county infirmary at Kildare, and fever hospitals at Celbridge, Naas, and Kilcullen; dispensaries are established in all the towns and chief villages. There are extensive cavalry barracks at Newbridge, and infantry barracks at Naas and Athy.

Population Table.

Date.	How ascertained.	Houses.	Families.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	Families not included in the preceding classes.	Males.	Females.	Total.

History and Antiquities.—In the antient division of Ireland the south-eastern portion of Kildare was included in the territory of Hy-Mail, of which O'Toole was prince; the south-western portion formed part of O'Connor's territory of Hy-Failge; the western division belonged to Hy-Ceallan, and a small portion of the north to the kingdom of Meath; with the exception of which last part the whole was included in the kingdom of Leinster. Leinster coming to Earl Strongbow by his marriage with Eva the daughter of Dermot MacMurrogh, was inherited by William Marshal, earl Pembroke, who married Isabel, only daughter and heir of Strongbow. He had issue five daughters, among whom the principality of Leinster was divided, A.D 1247. In this partition the county of Kildare was allotted to Sibilla, the fourth daughter, who married William earl Ferrers and Darby. Agnes, the eldest daughter of this marriage, was wife of William de Vescy, lord of Kildare and Rathangan, *jure uxoris*, and lord justice of Ireland. A dispute having arisen between him and Henry FitzThomas FitzGerald, lord of Ophaly, in A.D. 1293, it

was awarded to be settled by single combat; but Vescy, having fled into France to avoid the duel, was attainted of treason, and his estates bestowed on his antagonist. In 1296 Kildare, which up to this time had been under the jurisdiction of the sheriff of Dublin, was erected into a separate county. The Fitzgerald family, having subsequently adopted the pernicious system of Irish exactions, and usurped on the authority of the crown by trying all pleas before their own seneschals, to the exclusion of the king's sheriff, excited the hostility of the English government. Gerald earl of Kildare, being summoned to England to answer various charges of this nature to which he had exposed himself in his capacity of lord justice, left his son Lord Thomas Fitzgerald, a rash youth of twenty, his deputy. A report shortly after reached Ireland that the earl had been put to death, which so incensed Lord Thomas that he threw up his office of deputy, A.D. 1534, and entered into open rebellion, in which he was joined by the five brothers of the earl. Fitzgerald had at this time in his possession the six principal castles of Maynooth, Rathangan, Portlester, Athy, Loix in the present Queen's County, and Carlow. Maynooth and Rathangan being taken in 1534, he and his uncles submitted in the ensuing year. They were sent to England, and executed at Tyburn, Feb. 3, 1537. The earl had already died a prisoner in the tower of London. A younger brother of Lord Thomas, called Gerald, escaped during these disasters to the Continent, where he distinguished himself in the service of the Knights of Malta, and afterwards became master of the horse to the Grand Duke of Tuscany. In 1552 he was reconciled to the English government, and restored to his possessions.

This county was the theatre of various military operations during the wars which succeeded the rebellion of 1641. Of these the most important was the battle of Kilrush, fought 15th April, 1642, between the royalists under the earl of Ormond, and the Roman Catholic army under Lord Mountgarret, which latter party suffered a signal defeat. The number engaged on both sides amounted to about 15,000 men. The Kildare family were active in bringing about the Restoration, and espoused the Protestant cause in the subsequent wars of the Revolution of 1688. The forfeitures within this county attending on the latter event comprised 44,281 acres, valued at that time at 205,175*l.* 0*s.* 6*d.* The principal persons attainted were of the families of Eustace, Tyrrell, Lawless, and Trant. Several sanguinary engagements took place between the king's troops and the insurgents in this county in 1798. At Old Kilcullen the rebels had a temporary advantage, but were finally defeated here, as in various other parts of the county.

Numerous earthen works, partly military and partly sepulchral, remain in this county. Of the first class, the most remarkable are the rath of Knockawley, the antient palace of Allen, about a mile west from Old Kilcullen, the moat of Mullamast, the antient Carmon, near Ballytore, and Rath-Ardscull near Athy. There are numerous sepulchral mounds on the Curragh; and here in the time of Giraldus Cambrensis was a stone monument similar to Stonehenge. Pillar stones of large dimensions are still standing at Mullamast, Kilgowan, Forenaghts, Punch's Town and Harristown. There are round towers at Kildare, Taghadoe, Kilcullen, Castledermot, and Oughterard. Among the ruins of the numerous religious houses of this county, the most remarkable are those of the cathedral church at Kildare, the Franciscan abbeys at Castledermot and Clane, Great Connell Abbey on the bank of the Liffey near Newbridge, and the remains of several religious establishments in Naas. At Castledermot, Moone, and Old Kilcullen are stone crosses ornamented with curious sculptures. The castles of Athy, Maynooth, Kilkea, Rheban, Castledermot, Kilberry, Woodstock, Castle Carberry, Ballyteague, Clane, Lackagh, Donadea, Kildare, Leixlip, Timolin, Corifig, and Morristown Nenagh are still standing. The castles of Kilkea, Donadea, and Leixlip are still inhabited.

This county is partly in the diocese of Dublin, but chiefly in that of Kildare, which, in point of education, rank respectively 19th and 8th among the 32 dioceses of Ireland. It contains the two principal Roman Catholic Educational Establishments in Ireland, at Maynooth and Clongoweswood. The Royal College of St. Patrick, Maynooth, was founded pursuant to an act of the Irish parliament passed in 1795. The object of the institution is to provide a home-education for the Irish priesthood of the Roman Catholic Church, who were formerly obliged to resort to the Continental colleges. It was first opened for the reception of fifty students, in October, 1795. A lay-college was shortly after attached; but this was discontinued in 1817. The buildings now accommodate 450 students. Of this number 250 are free students, who are selected by the bishops of the several dioceses at yearly provincial examinations; and pay eight guineas at entrance, which is their only expense. The remainder are either pensioners who pay twenty-one guineas per annum and four guineas entrance, or half pensioners who pay only half the annual sum. The establishment is supported by these payments, by private bequests, and by a parliamentary grant of 8,928*l.* per annum. The college is governed by a president, vice-president, dean, and procurator, or bursar: there are professors of the sacred scriptures, of dogmatic theology, of moral theology, of natural and experimental philosophy, of logic, of belles lettres, Hebrew, Greek, and Latin, English elocution, and of the Irish and French languages. The students rise at half-past five o'clock, and retire to rest at half-past nine in the evening. The period of study is usually five years, of which two are devoted to humanity, logic, and mathematics, and three to divinity, but the course is sometimes shortened by the omission of mathematics. The building consists of a plain centre with extensive returning wings. The cost of its erection, before some late additions had been commenced, was about 32,000*l.* There are fifty-four acres of land attached, which are laid out as a park for the recreation of the students.

The lay-school at Clongowes, near Clane, was opened as a seminary for the sons of the Roman Catholic nobility and gentry in 1814. It is conducted by Jesuits, of whom there are forty-five resident in the institution. The building is a spacious quadrangle flanked by round towers, and has an imposing appearance. There is a museum, library, and theatre for lectures in natural and experimental philosophy. The institution is governed by a president, dean, and procurator, or bursar. There are six professors of various branches of the classics, a professor of mathematics, and a professor of natural philosophy. The course of education is more extended in classics than in the sciences.

The county expenses are defrayed by grand jury presentment. The amount levied in the year 1835 was 19,554*l.* 18*s.* 9*d.*, of which 1221*l.* 7*s.* 10*d.*, for public roads, was charged to the county at large; 6051*l.* 12*s.* 5*d.*, for public roads, was charged to the several baronies; 5206*l.* 7*s.* 8*d.* was for the public establishments of the county; 4713*l.* 15*s.* 10½*d.* for police, and 2304*l.* 14*s.* 11½*d.* in repayment of loans advanced by government.

(*Statistical Survey of Kildare; Transactions of the Geological Society*, vol. v.; Cox's *History of Ireland:* Brewer's *Beauties of Ireland; Parliamentary Reports, Papers*, &c.)

KILDARE, a bishop's see in the archiepiscopal province of Dublin, in Ireland. It comprises parts of the three counties of Kildare, King's County, and Queen's County, extending from east to west 46 statute miles, and from north to south 29 statute miles. The chapter consists of a dean, precentor, chancellor, treasurer, archdeacon, 4 prebendaries, and 4 minor canons.

In 1792 there were in this diocese 81 parishes, constituting 31 benefices, having 28 churches of the establishment. In 1834 the numbers were, parishes 80, benefices 41, churches of the establishment 35, other places of Protestant worship 4, Roman Catholic places of worship 110. In the latter year the gross population of the diocese was 134,356, of whom there were 13,907 members of the Established Church, 9 Presbyterians, 384 other Protestant Dissenters, and 120,056 Roman Catholics, being in the proportion of 8¾ Roman Catholics to 1 Protestant nearly. In the same year there were in this diocese 215 daily schools, educating 12,633 young persons of both sexes, being in the proportion of 9·4 per cent. of the entire population under daily instruction, in which respect Kildare ranks eighth among the 32 dioceses of Ireland. Of the above schools 44 were, in 1834, in connection with the National Board of Education.

The foundation of this see is ascribed to St. Conlaeth, a follower of St. Brigid, by whose assistance he is said to have founded the original cathedral in the beginning of the sixth century. Aodh Dubh, who died A.D. 638, is the next bishop whose name has been preserved. He had been king of Leinster, but retired from secular affairs and became successively monk, abbot, and bishop of Kildare. The see was

for seven years vacant between the death of Simon of Kilkenny, A.D. 1272, and the succession of Nicholas Cusack, declared bishop by Pope Nicholas III., to whom a dispute respecting the election of two other candidates had been re ferred. William Miagh, who succeeded in 1540, was reckoned among the prelates who wished well to the Reformation His successor Thomas Lancaster was the first Protestant bishop; he was consecrated by Browne, archbishop of Dublin, July, 1550. The revenues of the see were greatly diminished by Alexander Craik, who was bishop from 1560 to 1564: he exchanged most of the lands and manors of the bishopric with one Sarsfield, taking some tithes of little value in return. On account of the poverty of the bishopric so caused, the bishops of Kildare have continued, since the year 1681, to hold the deanery of Christ Church in Dublin, and the preceptory of Tully in the county of Kildare in commendam. The quantity of land belonging to the see is 911 acres, and the gross annual revenue of the bishop, on an average of three years ending December 31, 1831, was 6451*l.* 13*s.* 3*d.* By the 3rd and 4th Will. IV., c. 37, this see when vacant becomes united to the see of Dublin, and the deanery of Christ Church and preceptory of Tully become united with the deanery of St. Patrick's, Dublin. The temporalities will then vest in the Ecclesiastical Commissioners. The bishop has no residence within the diocese. The choir of the cathedral is the only part now in use; the nave and transepts having been reduced to ruins in the parliamentary war. Near the cathedral are the ruins of a small building where the sacred fire of St. Brigid was formerly kept burning. This superstitious practice was suppressed by Henry de Loundres, archbishop of Dublin, in the 13th century, but was subsequently revived, and only ceased finally at the time of the Reformation.

(Ware's *Bishops;* Beaufort's *Memoir of a Map of Ireland; Parliamentary Returns.*)

KILKENNY, an inland county of the province of Leinster in Ireland; bounded on the north by Queen's County, on the east by the counties of Carlow and Wexford, on the south by the county of Waterford, and on the west by the county of Tipperary. Its southern and western limits are also those of the province of Leinster, of which this county forms the south-western extremity. According to the map constructed under the superintendence of the Society for the Diffusion of Useful Knowledge it lies between 52° 13′ and 52° 53′ N. lat., and between 6° 55′ and 7° 38′ W. long. Its greatest length from the Slienmargie Hills on the north to the river Suir on the south is 36 Irish or 45¾ statute miles. Its breadth varies from 15 statute miles at its southern extremity to 24 across the northern districts. The area, according to the above map, is 469,170 statute acres, or 733 statute square miles. It is estimated by Mr. Griffith at 536,686 statute acres, of which 417,177 are cultivated land and 96,569 unprofitable bog and mountain. The population in 1831 was 169,945, exclusive of the city of Kilkenny, the total population being 193,685.

The navigable rivers Barrow and Suir form the greater part of the eastern and the whole of the southern boundary of Kilkenny, and the partly navigable Nore traverses its entire length from north to south-east. The northern part of the district between the rivers Nore and Barrow, including portions of the Queen's County and county of Carlow, is occupied by a hilly tract of country, extending 15 statute miles by 20. In Carlow and Queen's County these elevations form a continuous range. On the Kilkenny side they spread into numerous lateral groups, the general direction of which is from north-north-east to south-south-west. The principal valley on this side is watered by the Dian river, which rises in the north-eastern extremity of the county, and passes through the village of Clogh and the town of Castlecomer. Being joined by the Dineen and Dubhglass rivers from the east, it runs into the Nore five miles north of Kilkenny city. The valley of the Nore, from the northern extremity of the county to this point, is confined between the declivities of the Castlecomer Hills on the east and two groups of similar formation rising from the right bank of the river towards Tipperary on the west. Between the two latter groups the low ground spreads westward by the neat town of Freshford, expanding into a rich plain which occupies the north-western extremity of the county, and contains the towns of Urlingford, Johnstown, and the village of Ballyspellan, famous for its spa. In a detached portion of this plain, surrounded by the lands of the Queen's County, is the well built town of Durrow, situated on a small stream running eastward to the Nore. The town is built in the form of an oblong square. most of the houses are slated, and many of them are occupied by genteel private families, led to reside here from the convenience of the situation, which is central to the places o chief importance in Kilkenny and Queen's County. This insulated district, containing about 2000 acres, originally formed a portion of the lordship of Ossory in the Queen's County, and was annexed to Kilkenny by act of parliament at the instance of the Earl of Ormonde. The object was to repress the outrages committed against the Earl's tenantry by the sept of the Fitzpatricks, who, when tried in the Queen's County, were always acquitted, but rarely escaped conviction when brought to Kilkenny. In the neighbourhood of Durrow is the residence of Viscount Ashbrook, and between it and Ballyragget on the road to Kilkenny is Ballycondra, the antient seat of the Viscount Mountgarret, whose descendants now possess the earldom of Ormonde. Ballyragget, another seat of the Butler family, is now a thriving town on the left bank of the Nore, 9½ miles north of Kilkenny city. Here is an old castle of the lords Mountgarret, which has been converted into a barrack. Five miles south-east of Ballyragget, near the road from Castlecomer to Kilkenny, is the remarkable cave of Dunmore. The entrance is by a picturesque hollow clothed with brushwood, at the extremity of which the cavern opens by a natural arch fifty feet high. There are several chambers within encrusted with stalactites and traversed by a subterranean stream. Southward from these hilly districts, the plain, which to this extent is confined to a narrow strip on each side of the Nore, expands across the entire central part of the county, spreading into Tipperary on one side and Carlow on the other, with an open undulating surface characteristic of the great limestone field of which it forms a part. The city of Kilkenny [KILKENNY, *City*] is situated on both sides of the Nore where that river enters the more open district. The Nore divides this central plain into two nearly equal portions. The chief drainage of the eastern portion is towards the Barrow, on one of the streams running into which the town of Gowran is situated. This place gave title successively to branches of the families of Butler and Fitzpatrick, and was in the fourteenth century the principal residence of the Earl of Ormonde, who had a very strong castle here. It was greatly decayed about the beginning of the present century, but is now improving. It is principally the property of Viscount Clifden, whose mansion, Gowran Castle, is in the vicinity. The demesne and deer-park are extensive and well timbered, and the house is a fine edifice. Thomastown, situated on the Nore 10½ miles south from Kilkenny, derives it name from Thomas FitzAnthony Walsh, seneschal of Leinster, by whom it was founded. The town has an appearance of antiquity, and is well situated for trade, the Nore being navigable up to this point. Mount-Juliet, the residence of the Earl of Carrick, is finely seated on the banks of the Nore near Thomastown. The banks of the river are steep and wooded, and the open country on each side to a great extent under demesne. The open district to the west is traversed by a considerable river called the Owenree, running eastward from the Tipperary boundary to the Nore, which it joins 3½ miles above Thomastown: the Munster river, which joins the Owenree from the north, forms the boundary between Tipperary and Kilkenny counties for several miles. Near the Tipperary boundary on the Owenree is Callan, a corporate town of some extent, but much decayed [CALLAN], and farther down the stream, the villages of Kells and Innisnag. Bennet's Bridge, a thriving village, is situated on the Nore 3½ miles above its junction with the Owenree. Beyond this central district the entire southern part of the county, with the exception of a strip of level land along the northern bank of the Suir, is occupied with hilly and mountainous tracts, connected on the east with the granite group of Carlow, and the west with the sandstone range of Slievenaman in Tipperary. On entering this district, the Nore, which from Durrow to Thomastown divides the county into two nearly equal portions, changes its course from south to south-east and runs by a deep valley to the Barrow, which it joins about 15 miles above the junction of their united streams with the Suir. The hilly district included between the two former rivers and the open country extending from Gowran to Thomas-

town is bounded towards the Barrow by a lofty range of hills terminated on the north by Brandon Mountain, which rises to a height of 1696 feet over the town of Graigue-na-managh on the Barrow. The range of Coppinagh bounds the district towards the open country on the west, extending from Mount Loftus near the Barrow to the heights above Innistioge on the Nore. Innistioge is a well built village of the larger class, having a handsome bridge ornamented with Ionic pilasters, and some remains of antient fortifications. From Innistioge eastward the banks of the river are clothed for several miles with the woods of Mr. Tighe's beautiful demesne of Woodstock. The scenery on both sides of this river from Thomastown to the Barrow, a distance of 13 miles, is in the highest degree picturesque. Between the ranges of Coppinagh and Brandon are several extensive valleys opening towards the Nore, which receives the Clodagh river from this side. A tongue of alluvial land called the Roer, extending above two miles in length, occupies the south-eastern extremity of the district at the point of junction of the Nore and Barrow; with the exception of this spot the western bank of the Barrow from Graigue to the Nore is precipitous, and in some places clothed with natural wood. South from the Nore the banks of the Ross river (by which name the united streams are known from New Ross to the harbour of Waterford) slope more gradually, and are highly cultivated. The hilly district west of the Nore and Ross rivers rises into mountains of considerable height and extent, of which the principal group, called the Walsh Mountains, lies between the Argula river running northward into the Nore above Innistioge, and the Kilmacow river running southward into the Suir above Waterford, and covers a space about ten miles in length by six in breadth. The pasturable part of this district is wholly occupied by dairy-farmers. The space between the southern declivities of the Walsh Mountains and other groups ranging towards Tipperary and the Suir is occupied to a breadth of from two to five miles by a level tract of rich land in which is situated the small but remarkably neat town of Pilltown, and the villages of Poleroan, Fiddown, and Kilmacow. In the vicinity of Pilltown are Bessborough, the seat of the Earl of Bessborough, a fine mansion containing some excellent specimens of the Italian and Flemish schools of painting, and Belline, a seat of the Walsh family, from whom the neighbouring district is named, where there is another good collection of pictures. A taste for art was very prevalent in this district in the beginning of the present century. The keeper of the village inn of Pilltown at that time possessed a cabinet collection, including pieces by Rubens, Vandyck, and Tintoretto. At the northern extremity of the hilly district is the village of Knocktopher, an antient seat of the Ormonde family, the ruins of whose castle are still standing. The fine mansion of Castlemorris, formerly the seat of the family of Montmorency-Morris, occupies a commanding site on the acclivity of the hill called King's Mountain near Knocktopher, in the vicinity of which is also a handsome residence of the Langrishe family.

The Suir is navigable for vessels of 120 tons up to the bridge of Carrick, which is situated in Tipperary close to the western limits of this county. At the bridge of Waterford it is in some places eight fathoms deep at low water. Ships of 800 tons ascend the Barrow to New Ross, and small vessels can ply as high as St. Mullins, about midway between Ross and Graigue, where the tide ends, and the Barrow navigation for lighters commences. The Nore throughout the upper part of its course from Durrow to Thomastown runs rapidly, and is subject to violent floods, having a fall of about 13 feet in a mile. From Thomastown to the Barrow it is navigable for boats carrying 10 to 15 tons. Vessels of 80 tons and upwards have been built at and below Innistioge. A canal from Thomastown to Kilkenny was commenced in 1755, and executed to a distance of four miles, but after the expenditure of large sums of money the works were abandoned.

Climate.—The general slope of the surface is to the south-east, which is the best aspect both for sun and shelter. Surface waters run off rapidly, and there is very little bog; the air is consequently dry and healthy. The substratum in general is either limestone or brittle schist, both conducing to a light mellow soil and early vegetation. Myrtles grow luxuriantly in the southern parts of the county; and an arbutus at Kilmacow in 1801 measured two feet seven inches round the stem, and covered a circuit of thirty yards.

Geology.—With the exception of the mountain groups of the south, the entire surface of Kilkenny is occupied by the floetz limestone of the central plain overlaid in the hilly districts north of Kilkenny city by the shale and sandstone of the Castlecomer and Killenaule coal-tracts. The coal formations are nearly co-extensive with the hilly districts; the limestone, where it forms the surface-rock, spreads into undulating plains sweeping round the hilly tracts, and occupying the intermediate valleys. The strata composing the coal districts consist of alternations of shale with argillaceous ironstone, compact quartzy sandstone, and sand stone slate. Each tract constitutes a separate basin, the strata in that of Castlecomer dipping from the edge towards the centre, so that the undermost strata appear on the outer edge, and the uppermost in the interior of the district. The coal raised from these beds is anthracite, or non-flaming coal, called also mineral charcoal, from its containing 94 to 96 per cent. of pure carbon. It is accompanied with culm, which is used extensively for burning lime; the coal itself is used for domestic purposes and malting. The Castlecomer district contains seven workable beds of different thickness, arranged one over the other. Of these the uppermost beds, being nearly free from sulphur, are the most valuable, and are now nearly exhausted. But the three lowest beds, containing an abundant supply, have never been worked except when they occur near the surface. The beds, in ascending order, consist of, 1st, a bed little more than one foot in thickness occurring at the height of about 800 feet above the limestone substratum; it has never been worked. Second bed, divided into two parts, each about one foot thick, by a layer of fine clay. The coal is somewhat slaty, particularly that of the lower member. This bed has been partially worked near the surface, but never to any considerable extent. The third bed, which is rather thicker and more solid than the second, is worked only in a few places. Fourth bed, usually composed of four feet of solid coal, and two feet of slaty coal; occurs over a great extent of the interior of the district, and is at present worked in several places. Fifth bed, one foot in thickness; not much worked. Sixth bed, the three foot coal, which has supplied the principal demand for upwards of a century, now nearly exhausted. The principal works are at Castlecomer, Clough, and Newtown. In 1836 the produce was 42,554 tons of coal, at from 15*s*. to 20*s*. per ton, and 53,354 tons of culm at 4*s*. to 5*s*. per ton. Workings are also carried on at Feroda and other places in the district for culm and coal, the produce of which, in 1836, was 18,500 tons of culm, at from 4*s*. to 6*s*. 8*d*. per ton. The stratum on which the three-foot bed rests has been found to answer remarkably well for fire-bricks and other articles which are exposed in use to a great degree of heat. That portion of the Killenaule, or Slieve Arda district, which extends out of Tipperary into this county, is not at present worked. The isolated tract north of Freshford produces nothing but culm. The limestone border generally follows the foot of these hills, but in some places it rises halfway up the acclivity, and in one or two instances forms considerable hills on the exterior. A deposit of limestone-gravel, including boulders of large dimensions, generally occupies the exterior hollows of these hills, which towards the south and south-east slope gradually to the central plain. The general colour of the limestone is a bluish-grey; the best for burning is of a blackish colour, and is found near Kilkenny and Thomastown. Iron, manganese, and silex are generally diffused through the limestone rock towards the borders of the coal tract, and prevent it from burning. Near Kilkenny it passes into a fine black marble, containing a great variety of impressions of madrepores and of bivalve and turbinate shells. These beds are extensively quarried, and the blocks dressed on the spot by a saw-mill driven by the Nore. The marble, which is sometimes procured of a jet-black, is manufactured into chimney-pieces, tombstones, &c.; it bears a very high polish, and can be raised in large blocks. The hall at Bessborough is supported by four Ionic columns, the shafts of which are each formed of a single block of marble from this quarry, ten feet six inches in height. Black primitive limestone also occurs at Ballyragget. The tract of limestone skirting the northern bank of the Suir is decomposed, along its northern boundary for a distance of several miles, into a friable marly rubble, which is extensively used for manure. The surface heats and slacks under rain as if it had been subjected to the action of fire, which appearance is confirmed by the fact of detached pieces of quartzy sand-

stone having been found among the decomposed calcareous strata in a vitrified state. Marl is found in large deposits in various other parts of the county. The mountain tract occupying the south of Kilkenny, with the exception of the primitive group of Brandon, consists of a nucleus of clay-slate surrounded by sandstone. The latter rock extends over the greater part of that portion of the Slievenaman group included in Kilkenny, and constitutes the entire tract of the Walsh mountains. The clay-slate again rises beyond the valley of the Argula, from which it extends eastward to the Ross river, and northward beyond the Nore, constituting the range of Coppinagh, and occupying the tract included between that range and the western declivities of the Brandon group. A margin of sandstone extends along the western foot of Coppinagh, so that the clay-slate is nowhere in contact with the field of limestone.

Minerals.—The chalybeate spa at Ballyspellin was much celebrated in the last century for its efficacy in the cure of cutaneous and scrofulous diseases. It is still visited by invalids, who derive considerable benefit from the waters; but its celebrity at present chiefly arises from the humorous verses of which Dean Swift and Mr. Sheridan have made it the subject. The water contains fixed air, iron, and probably fossil alkali. Essays concerning its properties, and in commendation of the air of the neighbourhood, were published in 1724 and 1725. There are chalybeates at Kilkenny city, Castlecomer, Coolcullen, and several other places in the county, but the waters have little efficacy.

Soil and Agriculture.—There is but a small portion of Kilkenny unfit for tillage. The hills of the northern district are round-backed and accessible; and the Walsh mountains are for the most part pasturable. The group of Brandon is the only considerable extent of rough land in this county. In the northern part of the Castlecomer coal-tract the soil is a moory turf lying over a stiff whitish clay, which is the poorest district out of the mountain region. From Castlecomer southward the soil is light and friable as far as Kilkenny, and becomes deep, rich, and capable of any tillage towards Gowran and thence to Thomastown. The neighbourhoods of Durrow and Johnstown are good tillage lands, and the valley of Freshford has some of the best ground in the county. The soil of the hilly tract south of Freshford is fitter for pasture, and this is also the character of the right bank of the Nore from Kilkenny to Bennet's Bridge. The district watered by the Owenree has an excellent soil, and yields great crops of wheat. The soil of the hilly country on the south is dry and kind, but it is badly enclosed and destitute of shelter. Some of the best wheat and meadow lands in the south of Ireland are situated in the level tract along the Suir.

About one-third of the level districts is in tillage. In the poor soil of the Castlecomer tract the proportion of tillage land is about five acres in the hundred, and in the Walsh Mountain district about nine. The total productive tillage of the county in 1802 was estimated at 66,361 acres, producing 156,000 barrels of wheat, 80,000 barrels of barley, and 19,500 barrels of bere, 100,000 barrels of oats, and 1,030,000 barrels of potatoes. The sales of grain in the several market-towns in 1826 and 1836 appear from the following table:—

	Barrels of Wheat of 20 stone.		Barrels of Barley of 16 stone		Barrels of Oats of 14 stone.	
	1826.	1836.	1826.	1836.	1826.	1836.
Kilkenny . .	34,000	36,350	1,146	1,909	18,000	36,800
Gowran, Goresbridge, & Graigue	20,396	27,746	10,206	10 676	19,756	7,646
Castlecomer, Ballyragget, & Durrow	3,262	6,522	1,200	26	1,060	1,250
Thomastown, Bennetsbridge, Ennisnag, & Kells	42,054	57,632	4,660	5,262	24,000	6,019
Callan . . .	7,460	11,010	1,390	2,090	3,260	5,827

There are two districts almost wholly occupied by dairy-farmers, the Walsh Mountains and the southern part of the Castlecomer tract. In the southern dairy district the sour milk is used for fattening pigs for the Waterford market: in the northern district the milk is sold, there being no convenient market for pork. More attention is paid to cleanliness by the dairy-farmers of the Walsh Mountains than by the others. Their strainers are usually of hemp, and sometimes of tin: among the northern dairies woollen strainers are generally in use. The wages of agricultural labourers are 8*d.* in winter, and, during the rest of the year, 10*d.* The average number of working days in the year is 145.

Manufactures.—The manufacture of carpets, diapers, and tapestry was introduced into the county by the Countess of Ormonde in 1359. James duke of Ormonde, about the middle of the seventeenth century, established and encouraged, at a great expense, both linen and woollen manufactures; and about the close of the same century the Bessborough family introduced the manufacture of linen into the southern parts of the county. None of these branches of trade however succeeded for any considerable length of time. The manufacture of blankets, which was carried on with great activity at Kilkenny from about 1745 to the beginning of the present century, has also declined. In 1822 there were, in the districts of Cork, Kilkenny, Moate, and Carrick-on-Suir, 3184 persons engaged in this manufacture, 9876 depending on them, 19,322 pieces annually manufactured, of the value of 199,100*l.*, with capital invested in buildings and machinery to the amount of 116,700*l.* At present all these districts do not manufacture to the extent of 20,000*l.* In 1831 the number of weavers of every fabric in Kilkenny county was 502, and of wool-combers two. A coarse frieze for home consumption is made among the peasantry.

In 1792 there were in Kilkenny 37 mills employed in the grinding of wheat and making of flour. The number is at present about the same; but the establishments are greatly increased in size and grinding power. They are chiefly on the Nore, which, between Durrow and Innistioge, drives 22 mills.

Civil Division.—Kilkenny is divided into the baronies of Fassadining, on the north-east, containing the towns of Castlecomer, population in 1831, 2436; Ballyragget, pop. 1629; and Clough, pop. 582: Galmoy, on the north-west, containing the towns of Durrow, pop. 1298; Urlingford, pop. 1366; and Johnstown, pop. 875: Gowran, on the east, containing the towns of Thomastown, pop. 2871; Graigue, pop. 2130; Gowran, pop. 1009; Innistioge, pop. 906; part of Bennet's-bridge, total pop. 426; and Goresbridge, pop. 634: Cranagh, on the west, containing the town of Freshford, pop. 2175: Shillelogher, also on the west, containing part of the town and liberties of Callan, total pop. 6111: Kells, on the south-west, containing the remainder of Callan, the town of Kilmaganny, pop. 514; and the village of Kells, pop. 402: Knocktopher, in the southern centre, containing the villages of Knocktopher, pop. 475, and Stoneyford, pop. 445: Ida, on the south-east, containing the village of Rossbercon, a suburb of New Ross, pop. 369: and Iverk, on the south, containing the town of Pilltown, pop. 634, and several villages. The county of the city of Kilkenny forms a separate division, containing 4 parishes, with a population of 23,741.

Of the above towns the following are corporate:—Callan, said to be by prescription; Gowran, by charter of 6 James I.; Innistioge, by 6 James I.; Kilkenny and Irishtown, by 3 and 7 James I. [KILKENNY, *City*]; and Thomastown, by 1 Mary and 13 James I. Prior to the Union each of the above towns and Knocktopher sent two members to the Irish parliament. The representation is at present limited to two county members and one for the county of the city. In 1836 the county constituency was 1477. The assizes are held at Kilkenny, and the general quarter-sessions at Kilkenny, Castlecomer, and Thomastown. The county court-house and gaol are at Kilkenny, and there is a bridewell at Thomastown. The number of criminal offenders committed to the county gaol in 1836 was 480, of whom 409 were males and 71 females. Of these 175 males and 5 females could read and write, 64 males and 9 females could read only, and 169 males and 57 females could neither read nor write. The police force in 1836 consisted of one resident magistrate, 10 chief constables, 51 constables, 341 sub-constables, and 22 horse of the constabulary; and 2 resident magistrates, 3 chief constables, 18 constables, 122 sub-constables, and 2 horse of the Peace Preservation police; the expense of maintaining whom during the year 1835 amounted to 21,167*l.* 11*s.* 8*d.*, of which 11,284*l.* 18*s.* 3¼*d.* was chargeable to the county. The district Lunatic Asylum is at Carlow. The county infirmary and fever hospital are at Kilkenny, and there are also fever hospitals at Freshford, Kells, Kilmaganny, and Rossbercon, with dispensaries in all the towns and chief villages.

History and Antiquities.—On the partition of Leinster among the daughters of William earl of Pembroke, A.D. 1247 [KILDARE], Kilkenny was allotted to Isabella, the third daughter, who married Gilbert de Clare, earl of Gloucester and Hertford; by him she had issue, among other children, Eleanor, who married Hugh le Despenser the younger, whose grandson Thomas le Spenser sold his castle and manor of Kilkenny to James Butler, third earl of Ormonde, in 1391. The other great proprietors were the families of Grace and Walsh, who possessed the districts of Grace's Country (nearly co-extensive with the barony of Cranagh) and the Walsh Mountains respectively. The former family descend from Raymond le Gros, one of the most distinguished of the Anglo-Norman invaders, who obtained this district with his wife Basilia, sister of Earl Strongbow. The latter are descended from other companions of Strongbow called Walshes or Welshes (in Irish *Brennagh*), from their having originally come from Wales; they were seneschals of the palatinate of Leinster under the De Clares. Both families lost their estates in the war of the Revolution of 1688. The early history of the county is chiefly occupied with the feuds of the family of Ormonde against the houses of Desmond or Kildare, which led to the abolition of their respective war-cries of *Butler-aboo* and *Crom-aboo* by act of parliament in A.D. 1494. The Graces also during this period were engaged in perpetual hostilities with the Fitzpatricks, Kavanaghs, and other Irish families, the tradition of which events still survives among the peasantry of Grace's Country. On the breaking out of the rebellion of 1641 the county of Kilkenny fell into the hands of the Irish with little opposition, Lord Mountgarret, an influential member of the Butler family, taking the lead among the insurgents. Many others of that family espoused the same cause, and suffered extensively by the subsequent confiscations. The bulk of the Butler possessions was however for a time preserved to the family by James earl of Ormonde, who conducted the royalist cause throughout these wars with the highest ability. He was raised to the dignity of a duke after the Restoration, which event he had been very instrumental in bringing about, and was three times lord-lieutenant of Ireland. On the attainder of James, the third duke of Ormonde, in 1715, the title fell into abeyance. The dukedom has not been revived, but the earldom is now enjoyed by a descendant of Butler of Kilcash, brother to the first, or, as he is commonly called, the great duke of Ormonde.

The defection in this county on the accession of King William III. was very general. The forfeitures comprised 30,152 acres of profitable land, of a total estimated value, at that time, of 68,161*l.* 5*s.* 6*d.* The chief attainted persons were Lord Galmoy, Oliver Grace, Robert Walsh, Edmund Morris, and various members of the families of Fitzgerald, Archer, Rothe, Dalton, Shee, Purcell, and Lawless. The chief landed proprietors at present are the earl of Ormonde and Ossory, earl of Carrick, marquis of Lansdowne, earl of Bessborough, Lord Viscount Clifden, Lord Callan, Lord Viscount Mountmorris, Lord Viscount Ashbrooke, earl of Courtown, Sir Edward Loftus, Bart., Sir William Morris, Sir J. Cuffe, Bart., and the families of Flood, St. George, Tighe, Bryan, Murphy, Bunbury, Walsh, Aylward, and Rothe.

Circular stone enclosures of the Pagan æra remain on the summits of the hills of Cloghmanta near Freshford, and Tory Hill, or Slieve Grian, near Kilmacow. The latter appears to have been a sepulchral cairn, enclosing a kistvæn, or stone chamber, on one side of the covering stone of which there is an inscription long supposed to have reference to Baal, but which is now believed to be of a modern date. The covering stone of the cromlech at Kilmogue, in the barony of Knocktopher, is 45 feet in circumference, and is elevated at one end 15 feet from the ground. Another cromlech at Ballyheniberry, in the barony of Iverk, has a covering stone 16 feet long, 10 feet broad, and 3 feet thick. There are numerous similar monuments of smaller dimensions throughout the county. The remains of raths and earthen tumuli are also of frequent occurrence. There are five round towers, one adjoining the cathedral church of St. Canice in Kilkenny, the others at Kilree, Tullocherin, Fertagh, and Aghaviller. Of the monastic ruins, the most extensive and interesting are those of Jerpoint Abbey on the Nore, two miles from Thomastown. This abbey was founded by Donogh, king of Ossory, in 1180, for Cistercian monks, and was liberally endowed. The abbot was a lord of parliament. The ruins occupy three acres, and are a fine specimen of the mixed Anglo-Norman and early English architecture. The more modern portions of the building are in the pointed style of the thirteenth century, and are distinguished by their elegance and lightness. The tombs of the founder and of several ecclesiastics still remain. At Graigue are the extensive remains of a Cistercian abbey, founded in 1212 by William Marshal, earl of Pembroke. A portion of the building has been lately roofed in and converted into a Roman Catholic chapel. There are considerable remains of the Dominican convent at Thomastown, of the Augustinian monastery at Innistioge, and of the Augustinian friaries at Kells and Callan. Of the numerous castles founded by the Anglo-Norman lords, the most considerable is Grandison Castle in Iverk, an antient seat of the Butlers. It has three round towers towards the Suir and two courtyards. The castles of Balleen, Ballyragget, Knocktopher, Gowran, Callan, Urlingford, and several others, belong to the same family. Courtstown Castle, the chief seat of the Graces, was a building of great extent and splendour; but the ruins have now nearly disappeared. There are numerous castles in the barony of Gowran founded by the Purcells. In Knocktopher fifteen castles of the Walshes are enumerated; and throughout the county are the remains of various other fortalices belonging to the families of Brennan, Cantwell, Morris, Curry, Shortall, and Fitzgerald.

Kilkenny is situated in the dioceses of Ossory, Cashel, and Leighlin, under which titles the educational statistics of the district will be found.

The county expenses are defrayed by grand-jury presentments. The amount levied in 1835 was 29,793*l.* 14*s.* 8½*d.* Of this a sum of 2603*l.* 11*s.* 6*d.* was for the public roads of the county at large; 5907*l.* 19*s.* 1*d.* was for the public roads, being the baronial charge; 7609*l.* 19*s.* 1*d.* was for the public establishments and salaries; 11,284*l.* 18*s.* 3¼*d.* was for police; and 2387*l.* 6*s.* 9*d.* for repayment of loans advanced by government.

(*Statistical Survey of Kilkenny*, Dublin, 1802; Brewer's *Beauties of Ireland*; Griffith's *Report on the Leinster Coal Tract*; *Transactions of the Geological Society*, vol. v. Lewis's *Topographical Dictionary of Ireland*, 1838; *Parliamentary Reports and Papers.*)

KILKENNY, a city and county of a city, included in the county of Kilkenny, in Ireland. The county of the city comprises 14,903 Irish or 24,140 statute acres on both sides of the Nore, about midway between Thomastown and Durrow. The city occupies an area of 235 Irish or 380 statute acres, of which about two-thirds are under cultivation. According to the map of the Society for the Diffusion of Useful Knowledge, it is situated in 58° 37′ N. lat and 7° 13′ W. long., and is distant from Dublin 57½ Irish or 73½ statute miles.

Kilkenny, signifying the church of Kenny or Canice,

takes its name from the cathedral church of the diocese of Ossory, founded here about the end of the twelfth century. The place was selected by the early Anglo-Norman invaders for the site of a castle, which, when partly built, was destroyed by Donald O'Brien, king of Thomond, A.D. 1193. As part of the territory acquired by Strongbow by his marriage with the daughter of Dermot MacMurrogh, it devolved on William Marshal, Earl Pembroke, who founded the present castle, A.D. 1195. The castle occupies a commanding site on the west bank of the Nore, which is here about 40 feet high and faced with masonry. The cathedral is seated on a gentle eminence on the same side of the river, at the opposite or northern extremity of the city. The small river Bregah running into the Nore about midway between these points divides the city of Kilkenny Proper from the separate corporation of Irishtown or St. Canice, the former having originally been a dependency on the castle, the latter on the cathedral. A large suburb occupies the opposite side of the river, and is connected with Kilkenny Proper and Irishtown by two handsome bridges. Besides the castle, William Marshal the elder founded the hospital and abbey of St. John, in John's Street, Kilkenny, A.D 1211; and William Marshal the younger founded the Dominican or Black abbey in Irishtown, A.D. 1225. The Franciscan abbey on the bank of the river was also founded by the same family, and completed in 1347. At this time Kilkenny was a place of great importance as a frontier town of the Pale and a place of assembly for councils of the nobility and parliaments. At the parliament held here A.D. 1367, before Lionel, duke of Clarence, was passed the celebrated statute of Kilkenny, by which the Brehon law was legally abolished, although it continued practically in operation until the time of James I. In 1391 James Butler, third earl of Ormonde, purchased the castle and manor from Thomas Le Spenser, to whom the possessions of the family of Marshal had descended; and the title and estate still continue in the family of the purchaser. In 1399 the earl of Ormonde received King Richard II. here, and entertained him with great splendour for fourteen days. In 1400 Robert Talbot, a nephew of the earl, walled in the town, and various grants for murage, pavage, &c. were made to the citizens during the succeeding century. Parliaments and vice-royal courts continued to be held in Kilkenny until the breaking out of the rebellion of 1641, when it became the head-quarters of the Roman Catholic party and the seat of the supreme council appointed to manage their affairs. The council was modelled on the plan of a parliament, consisting of two houses, one composed of temporal peers and prelates, the other of members delegated from counties and borough towns. Both sat in the same chamber, but the lords had a retiring-room for occasional consultation. The meeting was at the house of a Mr. Shee, in the Coal-market, which was standing in 1802. On the 23rd March, 1650, the parliamentary army, commanded by Oliver Cromwell, appeared before the town, which was garrisoned for the Roman Catholic party by Colonel Walter Butler. An attempt was made next day to carry the place by assault, but it failed, and on the 25th a battery was opened on the castle. A breach being effected, the assault was made twice that evening, but without success, and the breach was quickly repaired. Cromwell was about to abandon the siege when the mayor and townsmen admitted his forces into Irishtown. Here the besiegers were again repulsed in endeavouring to make their way through the Franciscan abbey into Kilkenny Proper. On the 28th however Ireton came up with 1500 men, on which the garrison surrendered on honourable terms, Cromwell himself complimenting them on their gallantry. In 1652 Cromwell's first high court of justice sat here, and occupied the same chamber which had been used by the supreme council.

The chief object of antiquity is the cathedral church of St. Canice. It is a cruciform building, surmounted by a low tower: it extends from east to west 226 feet, and from north to south 123 feet, dimensions greater than those of any other church in Ireland, except St. Patrick's and Christ Church, Dublin. The chapel of St. Mary in the north transept serves as parish church. The oldest parts of the building appear to be of the architecture of the early part of the thirteenth century. The nave is divided from the side aisles by pointed arches springing from black marble columns, between which are numerous altar-monuments. The choir with the chancel is 77 feet in length. It is fitted up with varnished oak, and has a noble east window. The whole building had fallen greatly to decay in the beginning of the eighteenth century, but was repaired by Bishop Pococke in 1756, and is now in good preservation. Of the original castle there remain three massive towers worked into large additions, in the French taste of the seventeenth century, made by James, duke of Ormonde, in 1682. The building occupies three sides of a quadrangle, having a garden and fountain in front and a lofty terrace towards the Nore. The principal apartment is the picture gallery 180 feet in length, which contains numerous portraits of historical interest, and commands magnificent views of Kilkenny and the valley of the Nore. The abbey-church of St. John's has been converted into a parish church, and retains a good deal of the character of the original building, which was remarkable for its tall and slender windows pierced so close to one another that the intervals were nearly mullions, from which peculiarity it had the name of 'the lantern of Kilkenny.' Black Abbey has been partly restored and converted into a church for Roman Catholics. The architecture of the western part and of the south transept ranks among the best examples of the modified pointed style of the fourteenth century to be met with in Ireland. The body and tower of the Franciscan friary are still standing, but roofless, and the former has latterly been used as a tennis-court.

Kilkenny was first incorporated by William Marshal the elder, and Irishtown by King Edward IV. Their governing charters are of the 7th and 3rd James I. respectively. The governing body of the corporation of Kilkenny consists of a mayor, aldermen, and 36 common councilmen, by favour of whom the freemen are admitted, and latterly by birth, servitude, and marriage also. The recorder is elected by the governing body. His court has a civil jurisdiction unlimited in amount in causes arising within the precincts of the corporation. The annual revenue of the corporation arises from tithes producing 987*l.* 13*s.* 9¾*d.*, lands producing 830*l.* 17*s.* 9½*d.*, and customs producing about 200*l.* per annum. The annual expenditure is about 1350*l.* The constitution of the corporation, which was originally of a popular character, has been gradually altered, until almost all power is vested in a select body. The governing body of Irishtown consists of a portreeve and burgesses. The burgesses have nominally the election of the portreeve, but he is in reality appointed by the bishop of Ossory. The jurisdiction of the recorder's court does not exceed 40*s.* Irish. The revenue of the corporation, which is about equal to its expenditure, is only 15*l.* per annum. Prior to the Union, Kilkenny and Irishtown returned two members each to the Irish parliament. The representation is now confined to one member for Kilkenny city. In 1836 the number of voters was 808. The right of voting is regulated by 2nd William IV., c. 88. Assizes for the county of the city are held twice a year, and quarter-sessions in rotation with the towns of Castlecomer, Thomastown, and Urlingford. The county and city court-houses are built on the site of an antient castle of the Graces. The city gaol is a small building badly arranged; but that for the county, situated on the west of the town, is spacious and well constructed.

The town is well built, and has a busy and cheerful appearance, particularly that portion of it constituting Kilkenny Proper. The building material is usually stone whitened or dashed with rough-cast. The duties of police are discharged by a Peace Preservation force of one chief constable, three constables, and seventeen sub-constables, the cost of maintaining whom, in 1835, was 712*l.* 15*s.* 10*d.* Up to the year 1836 the provisions of the Lighting and Cleansing Act of 9 George IV., c. 82, had not been put in force in Kilkenny. The environs are of a very pleasing character, and the Mall, extending a mile along the back of the unfinished canal, is an elegant promenade.

The blanket manufacture, although much decayed, is still carried on to a considerable extent. There is a small manufacture of coarse woollen cloth and linens; but the chief trade is in grinding, malting, brewing, and distilling. Tanning and the provision trade are also carried on extensively, and there are great fairs twice a year for wool and black cattle. In 1689 the number of houses in Kilkenny city was 507; in Kilkenny city, including Irishtown, the number of houses in 1777 was 2274; in 1788 the number was 2689, and 2870 in 1802. The following table is for the county of the city —

Population Table.

The grammar-school or college of Kilkenny is an antient foundation of Pierce Butler, earl of Ormonde and Ossory, and his wife, the Lady Margaret Fitzgerald, in the sixteenth century; and further endowed by the duke of Ormonde in 1684. By the charter granted on the latter occasion the children of the retainers of the duke of Ormonde may be presented for instruction in Latin, Greek, Hebrew, poetry, and oratory, gratis, and the children of townsmen of Kilkenny at half-price; all others to be received according to the rates of the chief schools of Dublin. On the attainder of James, third duke of Ormonde, the privilege of presentation lapsed to the provost and fellows of Trinity College, Dublin. At present the head-master receives an annuity of 140*l*. per annum from the Ormonde family. The number of scholars is about 45. A poor-school for about 150 children of both sexes is supported in St. Mary's parish by a bequest of 100*l*. per annum left by Mr. Evans, and by other contributions amounting to about 60*l*. annually. In the same parish is a poor-school, kept by nuns, for 400 females. A Mechanics' Friend Society, established in 1835, has a library of 700 volumes and a public lecture-room. A subscription library, containing 4000 volumes, with a news-room attached, has been open since 1811. The deposits in the Savings' Bank, established in 1815, amounted in 1835 to 23,784*l*.

(*Statistical Survey of Kilkenny*; Ledwich's *Essay on the Antiquities of Kilkenny*; Brewer's *Beauties of Ireland*; *Parliamentary Reports and Papers*.)

KILLALLA, a bishop's see in the archdiocese of Tuam, in Ireland. It comprises a large part of the county of Mayo, and a portion of the county of Sligo, extending from east to west 57 statute miles, and from north to south 27 miles. The chapter consists of a dean, precentor, and archdeacon, with five prebendaries. In 1792 there were in the diocese 25 parishes, constituting 11 benefices, having 12 churches of the Establishment. In 1834 the numbers were—parishes 27, benefices 13, churches of the Establishment 13, other places of Protestant worship 2, Roman Catholic places of worship 30. In the latter year the gross population of the diocese was 144,289, of whom there were 7729 members of the Established Church, 38 Presbyterians, 139 other Protestant Dissenters, and 136,383 Roman Catholics, being in the proportion of 18¼ Roman Catholics to one Protestant nearly. In the same year there were in this diocese 129 daily schools, educating 7413 young persons of both sexes, being in the proportion of 5·13 per cent. of the entire population under daily instruction, in which respect Killalla ranks twenty-seventh among the 32 dioceses of Ireland. Of the above schools, in 1834, there were four in connection with the National Board of Education.

St. Muredach, the son of Eochard, was consecrated first bishop of the see by St. Patrick, about A.D. 440. It has been held in commendam with that of Achonry since the accession of Meyler Magrath to the bishopric, A.D. 1607. The last bishop of the united diocese was Doctor James Verschoyle, on whose death in 1833 these sees became annexed to the archiepiscopal see of Tuam, according to the provisions of the 3 & 4 William IV., c. 37. The see lands, now vested in the Ecclesiastical Commissioners, comprise 33,668½ statute acres; the gross annual revenue, on an average of three years ending December, 1833, was 2600*l*. 11*s*. 10½*d*.

Killalla is situated at the mouth of the river Moy, and has a population of 1125. It is a place of some trade in the export of grain and the manufacture of coarse linen, but from its vicinity to the more thriving town of Ballina [MAYO], it has latterly declined. The cathedral, which was repaired in 1817, is an old building, and is used also as the parish church.

The diocese of Achonry extends from north-east to south-west 35 statute miles, and is 27 statute miles broad. It comprises a large portion of the county of Sligo, and a part of the county of Mayo, and bounds the diocese of Killalla on the south and east. The chapter consists of a dean, precentor, and archdeacon, with three prebendaries. In 1792 there were in the diocese 27 parishes, constituting nine benefices, having eight churches of the Establishment. In 1834 the numbers were—parishes 25, benefices 13, churches of the Establishment 11, Roman Catholic places of worship 35. In the latter year the gross population of the diocese was 114,422, of whom there were 5417 members of the Established Church, 143 Presbyterians, 27 other Protestant Dissenters, and 108,835 Roman Catholics, being in the proportion of 19½ Roman Catholics to one Protestant nearly. In the same year there were in this diocese 107 daily schools, educating 8498 young persons of both sexes, being in the proportion of 7·43 per cent. of the entire population under daily instruction, in which respect Achonry ranks seventeenth among the 32 dioceses of Ireland. Of the above schools, in 1834, 14 were in connection with the National Board of Education.

Achonry is a mean hamlet, in the barony of Leney, in the county of Sligo. The cathedral is used as the parish church. The see lands comprise 11,784 acres, from which the annual average income is 1481*l*. 6*s*. 9½*d*.

(Ware's *Bishops*; Beaufort's *Memoir of a Map of Ireland*; *Parliamentary Returns*.)

KILLALOE, a bishop's see in the archiepiscopal province of Cashel, in Ireland. The diocese extends upwards of 80 Irish or 100 statute miles, through the counties of Clare and Tipperary into the King's County; and includes also a small part of Queen's County, Galway, and Limerick. It varies in breadth from 7 to 25 miles Irish. The chapter consists of a dean, precentor, chancellor, treasurer, and archdeacon, and five prebendaries. In 1792 there were in the diocese 119 parishes, constituting 42 benefices, having 35 churches of the Establishment. In 1834 the numbers were—parishes 108, benefices 60, churches of the Establishment 56, other places of Protestant worship 5, places of Roman Catholic worship 111. In the latter year the gross population of the diocese was 379,076, of whom there were 19,149 members of the Established Church, 16 Presbyterians, 326 other Protestant Dissenters, and 359,585 Roman Catholics, being in the proportion of 18¼ Roman Catholics to one Protestant nearly. In the same year there were in this diocese 349 daily schools, educating 23,152 young persons of both sexes, being in the proportion of 6·19 per cent. of the entire population under daily instruction, in which respect Killaloe ranks twenty-fourth among the 32 dioceses of Ireland. Of the above schools, in 1834, 13 were in connection with the National Board of Education.

Killaloe, a small town on the Shannon, near the southern extremity of Loch Derg, takes its name from St. Lua, called Mo-Lua, who founded a cell there about the beginning of the seventh century. St. Flannan, his disciple, was consecrated first bishop of this see, at Rome, about A.D. 639. About A.D. 1195 the antient sees of Innis-Cathy and Roscrea were annexed to Killaloe, and in 1752 Killfenora was added. The united diocese of Clonfert and Kilmacduagh, having become vacant, is now, by the 3 & 4 William IV., c. 37, also annexed to Killaloe. The see lands of the diocese comprise 7528 acres, of an average annual value in 1831 of 4532*l*. 9*s*. 1*d*. The cathedral, which was erected by Donald O'Brian, king of Limerick, in 1160, is a crucifor-

building with a square tower. The episcopal palace is a handsome residence in a well planted demesne overlooking the Shannon, which here runs rapidly over a rocky channel. The stone-roofed cell of St. Molua stands near the cathedral. It is remarkable as a specimen of the building of the seventh century.

(Ware's *Bishops*; Beaufort's *Memoir; Parliamentary Returns.*)

KILLARNEY, a market and post-town in the barony of Magonihy and county of Kerry, in Ireland; distant from Dublin 147 Irish or 187 statute miles.

The establishment of Iron works by Sir William Petty on the eastern shore of the Lower Lake of Killarney led to the erection of the town, which is distant from the lake about a mile and a half. It continued a small place till about the middle of the last century, when the proprietor, Lord Kenmare, invited several respectable families to settle there, and erected some houses for the linen manufacture in the vicinity. Soon after a new street, now the High Street of the town, was built, and a commodious hotel erected for the accommodation of the numerous visitors who about this time began to be attracted by the beauty of the neighbouring scenery. The working of the copper-mines at Ross and Muckruss contributed to the increasing prosperity of the town; and it has now become a place of permanent residence for many inhabitants of the better class, as well as a favourite resort for great numbers of tourists each summer and autumn. It consists of two principal streets at right angles, with several smaller streets leading from them. At the southern end of the main street is the best part of the town, called Kenmare Place, near which is the entrance to Lord Kenmare's demesne, a finely timbered park, which greatly ornaments the approach to Killarney on this side. In the main street are two excellent hotels. Besides the church, which is a respectable old building, there is a large Roman Catholic chapel, a nunnery, and two subscription reading-rooms. The general appearance of the town is neat, and, during the summer and autumn, very animated.

Quarter-sessions are held here four times in the year, besides weekly petty-sessions. The court-house is a handsome stone edifice, having a bridewell attached. The old court-house has been converted into a theatre. Balls are occasionally given in the upper part of the market-house, which is an old building, now chiefly appropriated to the sale of linens. There are a fever-hospital, dispensary, and almshouse for the aged women, the last supported by the countess of Kenmare. There is a free-school for 400 males, under the superintendence of the Roman Catholic clergymen, and another for 300 females, attached to the nunnery, both of which are liberally patronized by the Kenmare family. There is also a free-school for 44 males and 34 females, under the superintendence of the clergymen of the Established Church, and a national school.

The number of inhabited houses in Killarney, in 1831, was 936; and of inhabitants 7910, of whom 6715 were in the parish of Killarney, and 1195 in the parish of Aghadoe.

(Smith's *Antient and Present State of the County of Kerry*; Frazer's *Guide-book for Ireland*, Dublin, 1838; *Parliamentary Reports and Papers.*)

KILLARNEY LAKES. [KERRY.]

KILLAS, the local name of a group of rocks in Cornwall, ranked by geologists with the clay-slate, or grauwacke slate of other countries. The term is perhaps most properly applied to denote fissile argillaceous rocks, such as are usually called clay-slate; but it is often extended to other earthy compounds allied to these by geological position. (See Rev. J. Conybeare, *Ann. Phil.*, new series, vol. vi.) Near granite the killas is supposed by many geologists to undergo great alterations of character, to become 'metamorphic,' so as to assume more or less of the characters of pyrogenous rocks. In these 'altered' rocks lies a great part of the mineral wealth of Cornwall; tin and copper veins abound in them, as well as in the contiguous granite, to whose influence their mineral characters are ascribed. Dr. Borlase, in his work 'On the Geology of Cornwall,' assigns to these rocks the title of Cornubianite.

KILLENITE, a mineral which occurs both crystallised and massive. The crystals are imperfect: the primary form appears to be a rhombic prism. Cleavage parallel to the lateral faces and short diagonal; fracture uneven; structure lamellar; colour greenish and brownish yellow; streak yellowish-white; lustre glimmering, dull, vitreous; translucent; opaque; specific gravity 2·698; hardness 4·0; scratched by the knife; frangible.

By the blow-pipe becomes white, swells up, and fuses into a colourless enamel.

It occurs in granite veins at Killeny near Dublin, and is stated by Dr. Thomson to consist of

Silica	49·08
Alumina	30·60
Potash	6·72
Oxide of iron	2·27
Water	10·
	98·67

KILLFENORA, a bishop's see in the archiepiscopal province of Cashel, in Ireland. It is confined to the baronies of Burrin and Corcomroe, in the county of Clare, and extends only 23 statute miles by 11. The chapter is the same with that of Killaloe, excepting the prebendaries. In 1792 it contained 19 parishes, constituting eight benefices, having three churches of the Establishment. In 1834 the numbers were—parishes 19, benefices 6, churches of the Establishment 3, other places of Protestant worship 1, Roman Catholic places of worship 15. In the latter year the gross population of the diocese was 36,405, of whom there were 235 members of the Established Church, 4 Presbyterians, and 36,166 Roman Catholics, being in the proportion of 151¼ Roman Catholics to one Protestant nearly. In the same year there were in this diocese 28 day-schools, educating 2256 young persons of both sexes, being in the proportion of 6·14 per cent. of the entire population under daily instruction, in which respect Killfenora ranks twenty-fifth among the 32 dioceses of Ireland. Of the above schools, in 1834, there were not any in connection with the National Board of Education.

There are no authentic accounts of this see, which was antiently called Fenabore and Cellumabrach, till A.D. 1265, when one Christian was bishop. Killfenora was first united to Clonfert A.D. 1741, and subsequently to Killaloe A.D. 1752, which union still subsists. The see lands comprise 9237 acres. The income is included in that of Killaloe. The cathedral serves as a parish church; it is a respectable building, with a massive square tower.

(Ware's *Bishops*; Beaufort's *Memoir; Parliamentary Returns.*)

KILLINEY, a village near Dublin, where the junction of the granite and schist of the Wicklow mountains may be advantageously observed. The granite is hard, and contains plumose mica. The edges of the schistose strata repose on a basis of granite. 'The schist is much contorted, and sometimes so convoluted as to form concentric crusts. At the line of junction the schist abounds in crystals of andalusite grouped in a stelliform manner. Numerous veins issue from the granite, and intersect the micaceous schist. These veins frequently contain fragments of micaceous schist.' (Dr. Scouler, *Memoranda of Objects of Geological Interest in the Vicinity of Dublin*, 1835.)

KILMACDUAGH, a bishop's see in the archiepiscopal province of Tuam, in Ireland. It lies wholly within the county of Galway, extending along the south-western boundary of that county 23 statute miles by 15. The chapter consists of a dean, provost, chancellor, archdeacon, and two prebendaries. In 1792 it was divided into 60 parishes, constituting 15 benefices, having 14 churches of the Establishment. In 1834 the numbers were—parishes 21, benefices 4, churches of the Establishment 4, other places of Protestant worship 1, places of Roman Catholic worship 14. In the latter year the gross population of the diocese was 46,132, of whom 656 were members of the Established Church, and 45,476 were Roman Catholics, being in the proportion of 69¼ Roman Catholics to one Protestant nearly. In the same year there were in the diocese 53 schools, educating 3551 young persons of both sexes, being in the proportion of 7·70 per cent. of the entire population under daily instruction, in which respect Kilmacduagh stands sixteenth among the 32 dioceses of Ireland. Of the above schools, in 1834, there were not any in connection with the National Board of Education.

The see was founded by Colman, the son of Duach, a relative of Guair, king of Connaught, who endowed the bishopric with large possessions about the end of the sixth century. Stephen Kerovan, bishop of Kilmacduagh, was translated to Clonfert A.D. 1582, since which time these sees have been united. By the 3 & 4 William IV., c. 37,

the united dioceses are now annexed to the see of Killaloe and Killfenora, and their temporalities vested in the Ecclesiastical Commissioners. The see lands consist of 3950½ statute acres, producing an average annual income of 875*l.* The cathedral, a modern edifice, is situated in the town of Gort. There are some remains of the abbey founded by St. Colman at Kilmacduagh, and a round tower which leans remarkably from the perpendicular.

(Ware's *Bishops;* Beaufort's *Memoir; Parliamentary Returns.*)

KILMARNOCK, a market-town and parish in the district of Cunningham and shire of Ayr, 65 miles south-west by west from Edinburgh. It is surrounded by a fertile and populous district, and is well supplied with coal from the neighbouring mines. Its situation however is low, and up to the beginning of the present century it was considered the most irregularly-built town in this part of Scotland. During this century acts of parliament have been passed for cleansing, lighting, and paving the streets, and at present it contains some handsome modern houses, a bank, bridewell, workhouse, and commodious grammar-school. Kilmarnock is the principal manufacturing town of Ayrshire for woollen and cotton goods, and is more particularly noted for the weaving of shawls and carpets, of which it exports so large a quantity, that the annual value of these two branches of manufacture is alone estimated at 100,000*l.*

Kilmarnock was erected into a free burgh of barony by the charter of James VI. in 1591, and anew by the charter of Charles II. in 1672. The property of the burgh is valued at 7892*l.*, its revenue at 380*l.*, its expenditure at 256*l.*, and its debt at 3675*l.* The population of the burgh and parish in 1831 was 18,093, having been increased by 5324 persons in the ten preceding years, in consequence of the general improvement which had taken place in the trade and manufacture of the town within that period. In union with Port Glasgow, Kilmarnock now returns one member to parliament. (*Local Reports of Commissioners on Scotch Corporations; Beauties of Scotland,* &c.)

KILMORE, a bishop's see in the archiepiscopal province of Armagh, in Ireland. It comprises portions of the counties of Fermanagh, Leitrim, and Cavan, and a small part of the county of Meath, and extends 74 statute miles in length by from 13 to 25 in breadth. It has a dean and archdeacon, but no chapter. In 1792 it was divided into 39 parishes, constituting 30 benefices, having 36 churches. In 1834 the numbers were—parishes 37, benefices 38, churches of the Establishment 45, other places of Protestant worship 5, places of Roman Catholic worship 76. In the latter year the gross population of this diocese was 296,305, of whom there were 46,879 members of the Established Church, 8736 Presbyterians, 97 other Protestant Dissenters, and 240,593 Roman Catholics, being in the proportion of 4¼ Roman Catholics to one Protestant nearly. In the same year there were in this diocese 446 schools educating 30,623 young persons of both sexes, being in the proportion of 10·33 per cent. of the entire population under daily instruction, in which respect Kilmore ranks second among the 32 dioceses of Ireland. Of the above schools 23 were, in 1834, in connection with the National Board of Education.

Prior to A.D. 1454 the bishops of this district took their title from Triburna, an obscure village of the territory of Brefre. In that year Andrew MacBrady, bishop of Triburna, by the consent of Pope Nicholas V., erected the parish church of St. Feliney of Kilmore into a cathedral; from which time he and his successors have had the present title. John Garvey, who was promoted to this see in 1585, was the first Protestant bishop. After his death in 1589, the see lay vacant until 1603. From 1629 to 1641 it was filled by William Bedell, a prelate of great piety and learning. [BEDELL.] By the 3rd and 4th William IV., c. 37, this diocese becomes united with that of Elphin on either falling vacant. On this union, the temporalities of Elphin vest in the Ecclesiastical Commissioners. On the archiepiscopal see of Tuam becoming void, the bishopric of Ardagh, hitherto united to it, will also be annexed to Kilmore. The see lands comprise 28,531 acres, producing an average annual income of 7477*l.* 17*s.* 0½*d.* The antient parish church of Kilmore serves as the cathedral. The bishop's palace is a large mansion situated in a fine demesne near the town of Cavan.

(Ware's *Bishops*; Beaufort's *Memoir; Parliamentary Returns.*)

KIMBOLTON [HUNTINGDONSHIRE.]

KIMCHI, DAVID, a very celebrated Jewish rabbi, was born in the twelfth century, in the south of France, and passed the greater part of his life at Narbonne. His father, Joseph Kimchi, and his brother Moses Kimchi, also enjoyed much reputation among their contemporaries: they both wrote several works on Hebrew grammar and commentaries on the Scriptures; but none of them have been printed with the exception of 'A Commentary on the Life of Ezra,' by Moses Kimchi, printed in the Rabbinical Bible of Venice, 1549; and also a Hebrew Grammar by the same author, Venice, 1624.

David Kimchi has always been regarded by the Jews as one of their most illustrious rabbis. He possessed such great influence among his contemporaries, that he was chosen, in 1232, arbiter of the controversy which had subsisted for some years between the Spanish and French rabbis respecting the opinions of Maimonides. He died about the year 1240.

The most important of his works are:—a Hebrew Grammar, entitled מכלול (*Michlol*), that is, 'Perfection,' Venice, 1545; Leyden, 1631; and frequently reprinted; 'A Dictionary of Hebrew Roots,' Naples, 1490; Venice, 1529, 1552; &c. Kimchi also wrote commentaries on almost all the books of the Old Testament: the most valuable are said to be those upon Isaiah. Many of these commentaries have been printed separately; the whole of them were published by Breithaupt, Gotha, 1713, 3 vols. 4to.

KINCARDINESHIRE, or the **MEARNS**, as it is commonly called, is a maritime county of Scotland, situated between 56° 47′ and 57° 8′ N. lat., and between 2° 5′ and 2° 45′ W. long. On the north and north-west it is bounded by Aberdeenshire; on the south and south-west by Forfarshire, and on the east by the ocean. Its greatest length from the bay of Aberdeen on the north to the mouth of the Esk on the south is about 30 miles; and its greatest breadth from Dunnotar Castle on the east to Mount Battock on the west is rather less than 20 miles. It contains 382 square miles, or 244,480 acres, of which 1280 are water: half the county is supposed to consist of cultivated land, woodland, improvable moor, &c., and half of mountains, hills, &c.

The Grampian range, whose extremity forms the promontory of Girdleness in this county, occupies the western, central, and more northern parts of Kincardineshire. Mount Caerloch, the highest summit in this county, rises 1890 feet above the sea level. To the south of the Grampians the county descends into what is locally termed the 'How or Hollow of the Mearns,' which is the eastern extremity of Strathmore. Strathmore commences at Stonehaven in this county and extends in a south-westerly direction as far as the Frith of Clyde. It contains about 50,000 acres of comparatively low, fertile, and generally well-cultivated land, comprising about 7000 acres of thriving plantations. Along the coast, from the North Esk river to Stonehaven, the soil consists chiefly of a deep strong loam on a clay bottom, and about 32,000 acres of this district are in a high state of cultivation, the remainder being occupied with pasture, moor, and woodland. A third arable district is comprised within the narrow valley of the Dee. In 1807 the stock of cattle was estimated at 24,825 head; of which 6236 were milch cows, and 5280 calves; and the sheep stock at 24,957, exclusive of lambs. The average rent of land in 1810 was 13*s.* 2*d.* an acre, and the annual value of real property as assessed in 1815 was 94,861*l.*; but since then many improvements have been introduced, and prosecuted with extraordinary spirit, and the value of the land proportionally augmented; thus in the parish of Bervie, the rent of the *Haugh* lands adjoining the sea is about 5*l.* per acre. The average rate of wages in the parish of Garvock for married servants employed in agriculture by the half-year is, for a man 5*l.* 10*s.*, and for a boy 1*l.* 15*s.*, both summer and winter. The practice of cutting down the crops at a fixed price per acre, usually 10*s.*, is becoming very prevalent. The ordinary duration of leases is 19 years. The tenant is bound to good husbandry, though generally allowed to consult his own interest, except where very unfair dealing appears. Farm buildings are but indifferent, and there is a general want of enclosures throughout the county. The people are for the most part cleanly in their persons, orderly in their conduct, and regular in their religious duties.

The mineralogy of this county is not of great importance. In the parish of Laurencekirk and many other

places there are lime-quarries, and as the stone is of excellent quality, a more abundant supply of fuel is all that is wanted to render them of great value.

The principal rivers are the Dee on the north, and the North Esk [FORFAR] on the south. The other streams, the Dye, Cowie, Carron, Bervie, and Luther, are small, but several of them contain valuable salmon fisheries. The cod and ling fishery along the coast commences in October and closes in July; and the haddock, skate, and turbot fishery, which is carried on with great activity, usually begins on the first of May, and closes about the middle of July. The herring-fishery has declined, in consequence, it is said, of the fish having forsaken that part of the coast. The weaving of dowlas, household linen, &c. is the chief manufacture of the county, and employs about 700 men. The county is divided into 21 parishes, the aggregate population of which in 1831 was 31,431, forming 7136 families, whereof 2976 were employed in agriculture, 2281 in trade, handicraft, &c., and 1879 not comprised in the preceding classes. In all the parishes there are, beside the parochial-school, several unendowed private schools, wherein writing, arithmetic, and English grammar are taught. The county returns one member to Parliament. The principal towns are Stonehaven, the county town, Bervie [BERVIE], Johnshaven, and Laurencekirk. Of these towns, Bervie unites with Montrose, Aberdeen, Brechin, and Aberbrothwick in returning one member to parliament.

The old town of Stonehaven is reputed a burgh of barony, but the charter of erection is not known to exist, neither has its date been ascertained. It is conveniently situated near the mouth of the Carron river, and possesses an excellent harbour, sheltered on the south-east by a high rock, which runs out into the sea, and on the north-east by a quay, well adapted for the loading and unloading of goods To the north of the old town, but adjoining to it, is the new town of Stonehaven, which in point of wealth and population is of much greater importance than the other. It has risen suddenly, and is rapidly increasing, but it is neither lighted nor watched, and very imperfectly cleaned, from want of power to remove the dunghills kept at the doors of the inhabitants. The old town has long been supplied with water from private wells, and a company has been formed within the last few years for the supply of the new town. According to the local reports of Commissioners in 1836, the wealthier part of the inhabitants were then very anxious to adopt the new Police Act, but the majority of the town were opposed to all assessment. The population, which in 1835 was estimated at 3050, is rapidly increasing. This is attributed partly to the cultivation of waste lands and partly to the increase of manufactures.

(*New Statistical Account of Scotland; Beauties of Scotland; Parliamentary Papers*, &c.)

KING. The primary use of this word is to denote a person in whom is vested the higher executive functions in an independent state, together with a share, more or less limited, of the sovereign power. The state may consist of a vast assemblage of persons, like the French or the Spanish nation, or the British people, in which several nations are included; or it may be small, like the Danes, or like one of the states while in England there were seven states independent of each other; yet if the chief executive functions are vested in some one person who has also a share in the sovereign power, the idea represented by the word *king* seems to be complete. It is even used for those chiefs of savage tribes who are a *state* only in a certain loose and colloquial sense of the term.

It signifies nothing whether the power of such a person is limited only by his own conscience and will, or whether his power be limited by certain immemorial usages and written laws, or in any other way; still such a person is a king.

Nor does it signify whether he succeed to the *throne*, the seat on which he sits when in the exercise of his royal authority, by descent and inheritance on the death of his predecessor, just as the eldest son of a peer succeeds to his father's rank and title on the death of the parent, or is elected to fill the office by some council or body of persons selected out of the nation he is to govern, or by the suffrages of the whole nation. Thus there was a king of Poland, who was an elected king; a king of England, who succeeded by hereditary right.

Still in countries where the kingly office is hereditary, some form has always been gone through on the accession of a new king, in which there was a recognition on the part of the people of his right, a claim from them that he should pledge himself to the performance of certain duties, and generally a religious ceremony performed, in which anointing him with oil and placing a crown upon his head were conspicuous acts. By this last act is symbolised his supremacy; and by the anointing a certain sacredness is thrown around his person. These kinds of ceremonies, we believe, are found in all countries in which the sovereign, or the person sharing in the sovereign power, is known as king; and these ceremonies seem to make a distinction between the succession of an hereditary king to his throne and the succession of an hereditary peer to his rank.

The distinction between a king and an emperor is not very clearly defined. *Emperor* comes from *imperator*, a title used by the sovereigns of the Roman empire. When that empire became divided, each sovereign, that of the West and that of the East, called himself an emperor. These emperors claimed a kind of supremacy over other sovereigns. The emperor of Germany was regarded as a kind of successor to the emperors of the West, and the emperor of Russia (who was and is often called the Czar), is, with less pretension to the honour, sometimes spoken of as successor to the emperor of the East. But we speak of the emperor of China, where emperor is clearly nothing more than king, and we use emperor rather than king only out of regard to the vast extent of his dominions. Napoleon called himself an emperor; and we sometimes speak of the British empire. [EMPEROR.]

The word *king* is of pure Teutonic origin, and is found slightly varied in its literal elements in most of the languages which are sprung from the Teutonic The French, the Italian, the Spanish, and the Portuguese, on the other hand, have chosen to continue the use of the Latin word *rex*, only slightly varying the orthography according to the analogies of each particular language. *King*, traced to its origin, seems to denote one to whom superior knowledge had given superior power, allied, as it seems to be, to *know*, *con*, *can*; but on the etymology, or what is the same thing, the remote origin of the word, different opinions have been held, and the question may still be considered undetermined.

There are two or three other words employed to designate the sovereigns of particular states, in using which we adopt the word which the people of those states use, instead of the word *king*. Thus there is the *Shah* of Persia, the *Dey* of Algiers, and the grand *Sultan*. In the United States of America very limited powers are given to one person, who is elected to enjoy them for a short period with the title of *President*. A *Regent* is a temporary king.

A personage in whom such extraordinary powers have been vested must of necessity have had very much to do with the progress and welfare of particular nations, and with the progress of human society at large. When held by a person of a tyrannical turn of mind, they might be made use of to repress all that was great and generous in the masses who were governed, and to introduce among them all the evils and miseries of slavery. Possessed by a person of an ambitious spirit, they might introduce unnecessary quarrelling among nations to open the way for conquest, so that whole nations might suffer for the gratification of the personal ambition of one. The lover of peace and truth, and human improvement and security, may have found in the possession of kingly power the means of benefiting a people to an extent that might satisfy the most benevolent heart. But it must now by the long experience of mankind have become sufficiently apparent that for the king himself and for his people it is best that there should be strong checks in the frame of society on the mere personal and private disposition of kings, in the forms of courts of justice, councils, parliaments, and other bodies or single persons whose concurrence must be obtained before anything is undertaken in which the interests of the community are extensively involved. In most countries, as in England, there are controlling powers such as these, and even in countries in which the executive and legislative power are nominally in some one person absolutely, the acts of that person are virtually controlled, if by nothing else, by the opinion of the people, a power constantly increasing as the facilities of communication and the knowledge of a people advance.

Nothing can be more various than the constitutional checks in different states on the kingly power, or, as it is more usually called in England, the royal *prerogative*. Such a subject must be passed over in an article of confined limits

such as this must be, else in speaking of the kingly dignity it might have been proper to exhibit how diversely power is distributed in different states, each having at its head a king. But the subject must not be dismissed without a few observations on the kingly office (now by hereditary descent discharged by a queen) [QUEEN], as it exists among ourselves.

The dawn of the English kingly power is to be perceived in the establishment of Egbert, at the close of the eighth century, as king of the English. His family is illustrated by the talents and virtues of Alfred, and the peacefulness and piety of Edward. On his death there ensued a struggle for the succession between the representative of the Danish kings, who for awhile had usurped upon the posterity of Egbert, and William then duke of Normandy. It ended with the success of William.

This is generally regarded as a kind of new beginning of the race of English kings, for William was but remotely allied to any of the Saxon kings. In his descendants the kingly office has ever since continued; but though the English throne is hereditary, it is not hereditary in a sense perfectly absolute, nor does it seem to have been ever so considered. For when Henry I. was dead, leaving only a daughter, named Maud, she did not succeed to the throne; and when Stephen died, his son did not succeed, but the crown passed to the son of Maud. Again, on the death of Richard I. a younger brother succeeded, to the exclusion of the son and daughter of an elder brother deceased. Then ensued a long series of regular and undisputed successions; but when Richard II. was deposed, the crown passed to his cousin Henry of Lancaster, son of John of Gaunt, son of Edward III., though there were descendants living of Lionel, duke of Clarence, who was older than John among the children of Edward III. When the rule of Henry VI. became weak, the issue of Lionel advanced their claim. The struggle was long and bloody. It ended in a kind of compromise, the chief of the Lancastrian party taking to wife the heiress of the Yorkists. From that marriage have sprung all the later sovereigns, and the principle of hereditary succession remained undisturbed till the reign of King William III., who was called to the throne on the abdication of James II., when an act was passed excluding the male issue of James, the issue of his sister the duchess of Orleans, and the issue of his aunt the queen of Bohemia, with the exception of her youngest daughter the Princess Sophia and her issue, who were Protestants. On the death of Queen Anne this law of the succession took effect in favour of King George I., son of the Princess Sophia.

Now the heir succeeds to the throne immediately on the decease of his predecessor, so that the king, as the phrase is, never dies. But it is supposed that antiently there was a short intermission, and that the whole of the royal power was not possessed till there had been some kind of recognition on the part of the people.

At the coronation of the king he makes oath to three things:—that he will govern according to law; that he will cause justice to be administered; and that he will maintain the Protestant church.

His person is sacred. He cannot by any process of law be called to account for any of his acts. His concurrence is necessary to every legislative enactment. He sends embassies, makes treaties, and even enters into wars without any previous consultation with parliament. He nominates the judges and the other high officers of state, the officers of the army and navy, the governors of colonies and dependencies, the bishops, deans, and some other dignitaries of the church. He calls parliament together, and can at his pleasure prorogue or dissolve it. He is the fountain of honour: all hereditary titles are derived from his grant. He can also grant privileges of an inferior kind, such as rights of exclusive trading, and of markets and fairs.

This is but a very slight sketch of the power inherent in the kings of England; but the exercise of any or all of these powers is limited by two circumstances: first, the king cannot act politically without an agent, and this agent is not protected by that irresponsibility which belongs to the king himself, but may be brought to account for his acts if he transgress the law; and, secondly, the constant necessity which arises of applying to parliament for supplies of money gives to that body virtually such a control over the exercise of the royal prerogative, as amounts to a necessity of obtaining its concurrence in any public measure of importance. [PARLIAMENT.]

KING, WILLIAM, born 1650, died 1729, a native of Ireland, and a bishop and afterwards an archbishop in the Irish church. He is the author of two works on subjects of deep importance. One of these, 'The Inventions of Men in the Worship of God,' was intended to reconcile the Presbyterians of Ireland to the episcopal form of church order. But his greater work is his treatise on that difficult subject the Origin of Evil, which is written in Latin. His great object is to show that the existence of evil may be accounted for consistently with still acknowledging that God is great and good. These works excited much attention when they appeared, and the latter was attacked by two eminent foreigners, Bayle and Leibnitz, to whom he made no reply. But he left among his papers notes of answers to their arguments, and these were given to the world after his death by Dr. Edmund Law, bishop of Carlisle, together with a translation of the treatise itself. He printed also a sermon on the consistency of Divine Predestination and Fore-knowledge with the Freedom of Man's Will.

In politics he was a true friend to the Revolution. He was made dean of St. Patrick's, the first considerable piece of preferment which he enjoyed, in 1688. In 1691 he was made bishop of Derry, and in 1702 archbishop of Dublin. He was through life held in high esteem as a man, as well as in his character of a prelate and writer on theology.

KING GEORGE'S SOUND is situated on the south coast of Australia, not far from the south-western extremity of that continent, in 35° 6′ 20″ S. lat. and 118° 1′ E. long. It consists of an outer sound and two inner basins or harbours, which are perfectly land-locked and afford every security for ships. The northern basin, called Oyster Harbour, though spacious, is full of shoals, and has scarcely water enough to allow an approach to the beach: there is also a bar of sand fronting the entrance, which has never more than thirteen feet and a half of water. The other basin, called Princess Royal Harbour, is situated on the west side of the Sound; vessels of a considerable size may enter it, and ride at anchor close to the shore in perfect security. As there is no harbour within a great distance of it, either on the southern or western coast of Australia, which offers such advantages as King George's Sound, colonists were sent there from Sidney as early as 1826, and this settlement has been of great advantage to the colony of the Swan River, which was settled at a later date. It is very conveniently situated for the purposes of refreshment and refitting vessels bound to Cook's Land (New South Wales) and Tasmania (Van Diemen's Land), and is frequently resorted to by sealing vessels. The neighbouring coast to the eastward is fringed with numerous rocks and islands, upon which many seals of the black furred species are found. The country about it is partly hilly and partly level, and covered with swamps; it is of moderate fertility, but enjoys a fine climate and a sufficiency of rain for all the purposes of vegetation. The natives resemble those in the neighbourhood of Sidney, and are friendly disposed to the settlers. (Flinders; Nind, in *Journal of London Geogr. Society*, vol. i.)

KINGFISHERS, *Halcyonidæ*, a family of the *Fissirostral* tribe, of the order *Insessores*, or Perching Birds, according to the system of Mr. Vigors. [INSESSORES.]

In Willughby's 'Ornithology,' edited by John Ray, the 'Kingfisher—*Ispida an veterum Alcyon?*' is placed at the head of 'Land-Birds that feed upon Fish.'

Ray, in his 'Synopsis,' gives the bird the same title and position; but the heading varies a little from that of Willughby; for Ray makes the Kingfisher the first of his *Aves terrestres, aquas frequentantes, rostris longis, piscivoræ.*

Brisson arranged the Kingfishers (*Martin-pêcheurs*) in company with the Todies, as the two genera forming the third section of his fourteenth order, consisting of those birds which have the middle of the three anterior toes united to the external one up to the third joint, and to the internal one up to the first.

Linnæus placed the Kingfishers under his order *Picæ*, between *Todus* and *Merops*, with the generic appellation of *Alcedo*, and the following definition:—'*Bill* trigonal, thick, straight, and long. *Tongue* fleshy, very short, flat, and acute. *Feet* gressorial in most.'

Latham's second order, *Picæ*, is divided into three sections The third of these consists of birds with gressorial feet, and consists of the Motmots, the Hornbills, the Kingfishers, the Todies, and the Bee-eaters.

Lacépède's thirteenth subdivision consists of birds whose

external toes are united almost througnout their length (*Platypodes*): his seventeenth order (which, with the sixteenth, eighteenth, nineteenth, and twentieth, comes under this subdivision), consists of the genera *Alcedo* and *Ceyx*.

The tenth and last family of M. Duméril's second order (*Passereaux*) consists of the *Tenuirostres* or *Leptorhamphes*. It contains many genera, the Kingfishers, the Todies, the Bee-eaters, the Humming-birds, the Creepers, the Hoopoes, &c.

The fourth order in the method of M. Meyer comprises the genera *Merops* and *Alcedo* only.

Illiger's *Ambulatores* form his second order, the first division of which, the sixth in relation to the consecutive numbers, is termed *Angulirostres*. This division comprehends the genera *Alcedo* and *Merops* only. It is preceded by the *Syndactyli*, the last division of his first order, *Scansores*, and the *Syndactyli* consist but of one genus, *Galbula*. It is immediately succeeded by the *Suspensi*; and *Trochilus* is the only genus of this division.

Cuvier's *Syndactyles*, the fifth division of his second order, *Passereaux*, comprise the genera *Merops*, *Prionites*, (Motmots), *Alcedo*, *Ceyx*, *Todus*, and *Buceros*.

M. Vieillot makes the *Sylvicolæ* the second order in his arrangement. The second tribe of this order (*Anisodactyli*) is made up of numerous families. The twenty-fourth consists of the Bee-eaters and Kingfishers. It is immediately preceded by the *Epopsides*, and immediately succeeded by the *Antriades* (*Rupicola*), the twenty-sixth (*Prionotes*) consisting of the Motmots and *Calao* (Hornbills).

The *Alcyons*, the seventh order of M. Temminck, consist of the Bee-eaters, the Kingfishers (*Martin-pêcheurs*), and the King-hunters (*Martin-chasseurs*).

In the method of M. de Blainville his *Scansores* are divided into the *Hétérodactyles*, the *Zygodactyles*, and the *Syndactyles*. *Alcedo* (Linn.) is the representative of the latter. In the method of the same zoologist, as developed by M. Lherminier, the Kingfishers (*Martin-pêcheurs*—*Alcedo*, Linn.) are placed in the first or normal subclass, and form the thirteenth family, coming between *Merops* and *Buceros*.

Mr. Vigors, in his paper 'On the Natural Affinities that connect the Orders and Families of Birds,' observes, that if the genus *Todus* of authors be examined with reference to its general affinities, an intimate resemblance will be found between it and the succeeding group of *Halcyonidæ*; since the only species known when he wrote exhibits the exact representation of a Kingfisher, with the exception of a shorter and more depressed bill. He is of opinion that we are thus conducted to the *Halcyon* of Mr. Swainson, a genus which he thinks extremely distinct and well-defined (regretting however—and with justice—that the name had not been retained for that group of the family which includes the European Kingfisher, the bird known to the antients under that name), and from that genus to the *Dacelo* of Dr. Leach, until, in the more slender bill of *Alcedo*, is found an approaching conformity to the more delicately-shaped bills of the succeeding family of *Meropidæ*. In the group of *Halcyonidæ* he places the *Galbula* of Brisson, which, though distinguished from the groups of which Mr. Vigors is treating by its zygodactyle feet, and as such arranged by modern writers among the true *Scansores*, was, Mr. Vigors observes in continuation, originally included in the genus *Alcedo* by that great master of natural affinities, Linnæus, on account of the identity of the general structure and economy of both groups. Here Mr. Vigors thinks that it must necessarily be placed, if we look to natural affinity rather than the strict dictates of artificial arrangement; and with it he fancies may be placed some apparently conterminous groups, *Capito* of Vieillot, and some of its affinities, &c., of which the toes are equally disposed in pairs. The relationship of all to the true *Scansores* may, he says, be accounted for by the consideration of that tendency which opposite sides of a circle of affinity generally evince to approach each other. The very difference however between the feet of *Alcedo* and *Galbula* (which two groups, at the same time, he adds, it must be remarked, agree more intimately in every particular of the leg and foot, except the scansorial disposition of the toes, than *Galbula* accords with any of the *Scansores* in the same characters) is lost in a species of *Galbula* which Mr. Vigors had lately inspected from Brasil, where one of the hind toes is wanting, and where the foot thus exactly corresponds with that of the three-toed *Halcyonidæ*, or the genus *Ceyx* of M. Lacépède. The singular and beautiful species of the Linnæan *Alcedo*, the *Ternate Kingfisher*, which Mr. Vigors characterises as a genus under the name of *Tanysiptera*, shows, in his opinion, the equal approximation of that genus to *Galbula*, and a deviation from its own type, its tail deserting the shortened character of that of the true *Kingfisher*, and assuming the lengthened and graduated conformation of the same member in the *Paradise Jacamar* and the other long-tailed *Galbulæ*. Having now arrived at the last family of the tribe, Mr. Vigors directs us to look for that connecting affinity which will lead us back to that other family of it with which he commenced his observations. Here again, he remarks, the universally-acknowledged relationship between the *Halcyonidæ* and the *Meropidæ* leaves him nothing to observe. He refers to the gradually-attenuated bills of *Alcedo* and *Galbula*, and the increasing length of the tail in the latter genus, as softening down the differences by which these families, united by general habits and economy, alone appear to be separated. Thus the circular succession of affinities by which the tribe of *Fissirostres* returns into itself appears to Mr. Vigors to be complete.

The fifth and last family of M. Latreille's second order (*Passereaux*) consists of the Bee-eaters, Motmots, Todies, Kingfishers, the genus *Ceyx*, and the Hornbills. The fourth family comprises the *Tenuirostres*, and the *Scansores* (*Grimpeurs*) form the order which immediately follows the *Passereaux*.

The Prince of Musignano (C. L. Bonaparte), in his 'Tabella analitica de' Generi' (*Specchio Comparativo*, 1827), makes the tribe *Ambulatores* immediately follow the tribe *Scansores*. The first family of the *Ambulatores* consists of the genera *Alcedo* and *Merops*.

In M. Lesson's 'Projet' the third tribe (*Syndactyles*) of the first order, *Insessores* or *Scansores* (Grimpeurs), includes four families, in the following order:—*Meropidæ*, *Halcyonidæ* (Alcyonées), *Rupicolidæ* (Rupicolées), and *Buceridæ*.

In the 'Table Méthodique,' at the end of his 'Manuel,' he makes the family *Meropidæ* comprise the genera *Merops*, *Alcedo*, *Dacelo*, *Ceyx*, *Syma*, *Todiramphus*, *Momotus*, and *Buceros*.

Mr. Eyton, in his arrangement, published in his 'History of the Rarer Species of British Birds' (1836), makes his fourth family (*Tenuirostres*, Cuv.) of his second order (*Passeres*, Linn.) consist of three divisions:—1st, the *Anisodactyli*, Temm.; 2nd, the *Syndactyli*, Cuv.; and 3rd, the *Alcyones*, Temm. The latter division contains the genus *Alcedo*, Ray, whilst *Merops* is arranged under the *Syndactyli*.

Mr. Swainson, in the 1st volume of his 'Classification of Birds' (1836), when treating of the *Syndactyle* foot, allows the term to be good, if limited to such feet, with united toes, *as are of a different formation to all others*, and would not, even if the toes were free, come under any of the definitions which he had previously given. Such a form of foot, he says, will be found in the genera *Merops* and *Alcedo*, containing the Bee-eaters and Kingfishers, to whose feet, '*par excellence*,' he limits the term *Syndactyle*. 'The habits of these two groups,' continues Mr. Swainson, 'as far as concerns the use of their feet, are nearly the same, for in neither are these members ever employed but to rest the body. The Kingfisher watches patiently from a fixed station, generally a naked twig overhanging the water, for such fish as come within its reach, and then, after a time, flies to another station, where it alights and remains. The feet, from not being used for walking or standing, are consequently very small, and the toes imperfectly developed; there are three in front and one behind, but two of the former might be almost reckoned as only one, since they are united together even to the commencement of their respective claws; the inner toe is not half the length of the others, and seems rudimentary: it has a claw, and is rather more detached at its tip than the other two; in some, as in the three-toed Kingfishers, this inner toe disappears. The hinder toe is very short, and scarcely longer than the inner one; the scales of the whole foot are so thin and transparent that they can scarcely be seen in the small species by the naked eye. Those who have seen so much of the true Kingfishers, so scarce in England, but so common in Tropical America, know that they never perch upon any other than small or slender branches; and this we may infer from the shape of the foot. The two outer anterior

toes are very long, so that they would completely clasp two-thirds of the circumference of a small branch, the other third being embraced by the hinder toe. This fact is further confirmed by the unusual flatness of the soles of all, and by the acuteness of the claws, which, from being but slightly curved, would not upon a small branch come into contact with the wood; the union of the three anterior toes, by producing considerable breadth of sole, gives an unusual degree of steadiness to the bird, highly conducive to its remaining very long in one position. Thus we see that the foot of the Kingfisher, which at first appears so very imperfect, and so totally useless for ordinary purposes, is that which is most of all suited to the habits and the wants of the bird. The Bee-eaters, like the Swallows, feed upon the wing, yet, unlike those birds, they never perch upon the ground; at least we can affirm this of the European species (*Merops Apiaster*), which visits the island of Sicily every year in great numbers, and remains for near a month, on its passage from Africa to middle and southern Europe. During this period we have sought for many years every opportunity of detecting these birds in their resting position, but never were successful in finding them otherwise than on the tops of the olive-trees, where they rest immoveable until they again dart off for another long excursion. It is indeed obvious that they could not walk, for their feet are much the same as the Wood Kingfishers (*Dacelo*), with this only difference, that the three anterior toes are divided the whole length of their last joint, the scales being rather more conspicuous.'

In the second volume of the same work Mr. Swainson speaks of the *Halcyonidæ*, or Kingfishers, as obviously connected with the *Meropidæ*, next to which he arranges them. These comprise, he observes, several well-marked genera, agreeing among themselves in the great length of their bill and in the extreme shortness of their feet. These characters, he adds, it is true, belong also to the true Bee-eater; but a remarkable difference in economy is developed in the Kingfisher. 'We have seen,' continues Mr. Swainson, 'that the Goatsuckers, Swallows, and Bee-eaters traverse the air to search after and pursue their prey; their wings are consequently adapted for long and continued flight; but the family before us have a different economy, and therefore a different organization. The whole of the genera are sedentary, *watching* for their food from a fixed station, which they only quit as soon as their prey approaches sufficiently near to come within the sweep of their wings; if unsuccessful in their first attack, they do not pursue their game, but return again to their post, and patiently wait for another luckless straggler; if their first attack is successful, they return with their victim to the same station, and then proceed to swallow it. Every one knows that these are the habits of the European Kingfisher (*Alcedo ispida*), and travellers affirm that the Kinghunters (*Halcyon*) pursue the same method in the forests of the Old World. But it has unfortunately happened that systematic naturalists totally unacquainted with the natural habits of the other genera (nearly all of which are confined to Tropical America) have fancied they were climbing-birds, and have consequently placed them in other orders whose organization and economy are widely different. Thus the Jacamars, in the *Règne Animal*, are placed after the Hornbills, and the Puff-birds (*Tamatia*) are associated with the Cuckoos.'

The following characters are assigned by Mr. Swainson to the *Halcyonidæ*:—

Wings rounded, not formed for rapid flight. *Feet* very feeble. *Toes* in pairs.

And he makes the family consist of the following genera and subgenera:—Genus Tamatia, comprising *Tamatia*, Cuv.; *Capito*, Vieill.; *Lypornix*, Wagler; *Monassa*, Vieill.; and *Brachypetes*, Sw.—Genus Halcyon, Sw., including *Dacelo*, Leach; *Halcyon*, Sw.; *Syma*, Lesson; *Todiramphus*, Lesson; and *Ceyx*, Lacépède.—Genus Alcedo, Linn., comprehending *Alcedo; Ispida*, Sw.; *Tanysiptera*, Vigors; and *Alcyone*, Sw.—Genus Lamprotila, Sw.—Genus *Galbula*, Linn. (Brisson, we suppose, is meant; Linnæus has no such genus).

Tamatia. (Puff-Birds.)

Generic Character.—*Bill* straight, compressed. *Nostrils* defended by long, stiff, incurved feathers and bristles. *Rictus* strongly bristled. Toes versatile, as in *Cuculus* (Swainson).

Under the article BARBETS, vol. iii., p. 434, the reader will find a figure of *Tamatia macrorhynchos*, and Mr. Swainson's description of the habits of the *Puff-birds* in general. In his 'Classification of Birds,' vol. ii., the same author states that the Hermit Birds (*Monassa*) have similar habits, and frequently rise up perpendicularly in the air, make a swoop, and return again to their former station.

The subgenera he characterises as follows:—

Tamatia.—*Bill* moderate, thick, conic; the tip but slightly bent. *Tail* narrow. Conirostral (*T. maculata*, 'Braz. Birds,' pl. 11.)

Capito.—*Bill* long; the tip abruptly bent, so as to form a hook. *Tail* narrow, Dentirostral. (*C. leucotis*, 'Brazil. Birds,' pl. 11; *C. somnolentus*, *Ib.*, pl. 9.)

Lypornix.—*Bill* moderate, defended by very long bristles. Both mandibles nearly equal. *Wings* very short, rounded. *Tail* narrow. Tenuirostral. (*L. striata*, 'Brazil. Birds,' pl. 34; *L. rubicula*, *Ib.*, pl. 25.)

Monassa.—*Bill* as in *Lypornix*, without the basal bristles, but with short setaceous feathers. *Wings* short. *Tail* lengthened, and very broad. Scansorial. (*M. leucops*, 'Braz. Birds,' pl. 12.)

Brachypetes.—*Bill* as in *Lypornix*, but shorter, higher, and more curved; the margins greatly inflexed. *Wings* long. *Tail* short and even. Fissirostral. (*B. tenebrosa*, 'Braz. Birds,' pl. 35.)

Geographical distribution.—All these are inhabitants of the New World.

Halcyon.

Generic Character.—*Bill* long, very straight, cylindrical; the sides widened; the base more or less depressed; gonys ascending. *Feet* syndactyle. (Swainson.)

The following subgenera are thus characterized:—

Dacelo.—Margin of the upper *mandible* considerably sinuated near the tip. *Wings* lengthened; the quills slightly mucronate. *Tarsus* covered with rough scales. Australian range. (Sw.)

Example, *Dacelo gigantea*. White's 'Voy.,' pl. 2. (Sw.

Dr. Leach thus describes *Dacelo gigantea*, the *Gigantic Dacelo*, *Alcedo gigantea* of Latham, *Alcedo fusca* of Gmelin. *Body* olive-brown, beneath whitish; tail banded with black and ferruginous, the tip white; upper mandible blackish, under one whitish with a blackish base. *Male*, with its head slightly crested, the crest fuscous; legs yellow; belly banded with blackish. *Female*, with the crown of the head brown, without a crest; legs brown. (*Zool. Misc.*, vol. 2.)

Dacelo gigantea.

Locality.—Dr. Leach gives New Holland as the habitat, where, he adds, it is a very common bird; and he says that it is known by the appellation of *Gigantic* or *Great Brown Kingfisher*. In Governor Phillip's 'Voyage to Botany Bay'

(Lond. 4to., 1789), the *Great Brown Kingfisher* is described at length, with the observation that these birds vary much, the colours being more or less brilliant, and in some of them the tail is stated to be wholly barred with white and black, and the legs brown or blackish. The species is there said to inhabit various places in the South Seas, being pretty common in New Guinea; but the specimen, from which the figure given in the work was taken, was sent from Port Jackson, where it is said to be not unfrequently met with. It is the 'Laughing Jackass' of the colonists of Sydney; and *cuck'unda* of the natives, according to Lesson, who says it is very common on the banks of Fish River, where he killed a great number.

Halcyon.—*Bill* long, straight, broad, nearly quadrangular; culmen slightly inclining towards the tip, near which the margin is slightly sinuated; gape smooth. *Wings* broad, short, rounded. *Tail* very short. *Feet* syndactyle; scales of the *tarsus* obsolete. (Sw.)

Example, *Halcyon cinnamomina.* (Sw.)

The generic character above given appears in Mr. Swainson's 'Classification of Birds.' In his 'Zoological Illustrations' (1st series), he states that the two extreme points of difference in the Linnæan Kingfishers are seen in *Alcedo ispida* and *A. gigantea*, 'the last of which has been made into the genus *Dacelo*. It will nevertheless be found that from among the birds left in the old genus there are a great number (of which indeed this bird, *Halcyon cinnamominus*, as it is there named, 'is a striking example'), which are much nearer allied to *Dacelo* than to *Alcedo*, where they now stand. It will appear therefore more natural to consider *Halcyon* and *Dacelo* as one genus, which may be called by either name, but which must be distinguished by the characters herein given to *Halcyon*, inasmuch as the generic definition of *Dacelo* (founded on one bird) will be found too restricted to comprehend all.'

Mr. Swainson then proceeds to give the following description of '*Halcyon cinnamominus*, Cinnamon Crab-eater,' from a bird in the possession of Mr. Leadbeater, by whom it was received from New Zealand, and who gave Mr. Swainson the opportunity of publishing his figure and description.

Total length ten inches; bill two and a half from the gape, and one and a half from the nostrils; the tip of the upper mandible with a slight inclination downwards, and with an appearance of a notch; the whole head, neck, and under plumage of a delicate fawn colour; under wing covers the same; the remaining upper plumage with the wings and tail changeable blue-green; ears sea-green and dusky united to a narrow black nuchal collar; wings four inches long, and the tail, which is even, three and a quarter; the hind head is slightly crested, and the feet pale-brown.' (Sw.)

Halcyon cinnamomina. (Swainson.)

N. B. The sub-genus *Halcyon*, as given in Mr. Swainson's 'Classification of Birds,' vol. ii., consists of many species, and has a wide geographical distribution in the Old World.

Syma.—*Bill* long, enlarged at the base, compressed and thin on the sides towards its extremity, upper mandible slightly curved from the base to the point (which is very sharp), and longer than the lower mandible, which is carinated below and convex, and very sharp at its point, which is lodged in the groove (rainure) of the upper mandible; edges of both mandibles furnished for two-thirds of their length with sharp serrated teeth, strong and numerous, and directed from before backwards. Lower space around the eye naked. Third and fourth quills equal, long, the first short. *Tarsi* moderate, the three anterior *toes* united, the external toe shortest. *Wings* short. *Tail* moderate with unequal feathers to the number of ten great ones, and two external small ones. (Lesson.)

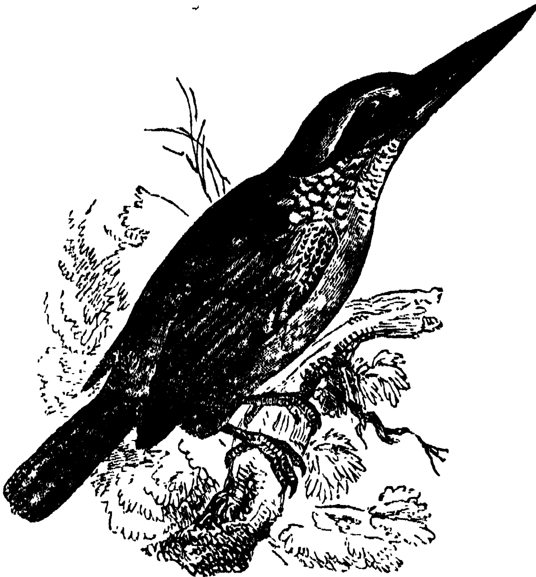
Example, *Syma Torotoro*, Less.; *Alcedo ruficeps*, Cuv.

Description.—*Length* seven inches from the tip of the bill to the extremity of the tail. The *Bill* two inches from the commissure to the point, and the tail twenty-seven lines. *Colour.*—Bill entirely of a brilliant golden yellow; head and cheeks of a bright uniform cinnamon yellow separated by a brighter tint in the form of a collar from the mantle (*manteau*) by two spots of a deep black, which do not entirely unite upon the neck. Around the eye a black circle; feathers of the mantle velvet-black, those of the wing-coverts uniform blue-green, rump bright green; quills brown within and bordered with metallic greenish externally; tail-feathers equal, of a rather deep-blue above and brown below. Throat of a light but very clear yellowish, which becomes deeper on the sides of the belly and breast, to become lighter and pass into whitish on the abdomen (bas-ventre). Feet rather strong, of a bright yellow; nails black. (Lesson.)

M. Lesson, who established this genus, states that it haunts the banks of the sea, among the Mangroves—*palétuviers*—(*Bruguiera*). He says that it skims the shores (grêves) for the purpose of seizing as it flies the small fishes which its strongly dentilated bill secures. He also observed many individuals skimming in their flight the waters of the small streams which are discharged into the harbour of Doréry at New Guinea, and he says that the Papuans name the bird '*torotoro*,' doubtless from its cry.

Todiramphus.—*Bill* straight (the lower mandible very slightly swollen or convex), very much depressed, wider than it is high, without any *arête*, the mandibles equal, obtuse at the end and flattened, the edges being entirely smooth. *Nostrils* basal, the fissure oblique and hardly apparent, bordered by the frontal feathers. *Wings* short, rounded; first quill shortest, and the fourth longest. *Tail* long, the feathers equal, and twelve in number. *Tarsi* elongated, moderate, and reticulated. (Lesson.)

Geographical Distribution and Habits of Todiramphus.—M. Lesson, who established this natural group, states that they live in the islands of the South Seas. They inhabit the woods, and perch almost constantly on the cocoa-palms (*Cocotiers*). Their nourishment is only composed of small flies (*moucherons*), which they seize when the insects come to pitch on the spathes charged with the flowers of the palm. The Islanders name them *O-tataré*. They were sacred birds, and it was forbidden to kill them under severe penalties. Their skins were offered to the great god *Oro*.



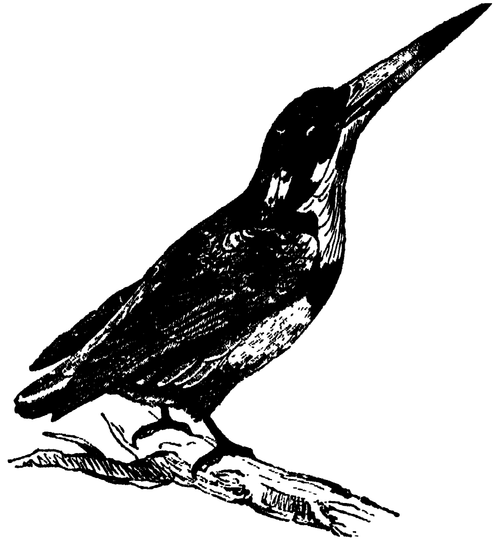
Example, *Todiramphus sacer*: *Alcedo tuta*, Gm. and Lath.; *Alcedo sacra*, Gm. and Lath.; *Sacred King's-fisher*, Lath.

Description.—Total *length*, eight inches six lines; bill, twenty-one lines from the commissure to the point; tail, three inches. *Bill* black, white at the origin of the lower mandible; summit of the head covered with brownish-green feathers, which form a sort of hood (*calotte*), separated by a large white streak which rises on the front, passes above the eyes, and continues behind the occiput. A large black line (*trait*) springs from the eye, and taking a tinge of green and then of brown, forms a border to the white line and circumscribes it. Throat, breast, and all the upper part of the body pure white; a very large, whitish, demicollar, waved (*sinuolé*) with light brown and very light chesnut, occupies the upper part of the mantle and is bordered with black; the back, coverts of the wings, rump, upper part of the tail and wings, are uniform bluish-green;

the greater quills are brown and blue on their external border; the other quills (*remiges moyennes*) terminated with brown. Tail brown below. *Tarsi* black. The *wings* extend to the upper third of the tail.

M. Lesson, whose description we have selected, says that the species is very common in the Islands of Otaheite, or Taheite, and Borabora. It perches on the cocoa-palms, and the natives call it *Otataré*. Its flight is short, and it is not timid. It lives on the insects which the honied exudations of the cocoa-flowers attract. This species and *Psittacus Tahitensis* remain constantly on the cocoa-nut trees, which form girdles on the shores of all those islands.

Dr. Latham remarks that his *Sacred King's-fisher* has been found in Dusky Bay, New Zealand, where it is called *Ghotaré*.



Todiramphus sacer (Sacred King's-fisher).

Ceyx.—*Bill* entirely straight, long, a little flattened vertically, the mandibles of equal height, smooth on their edges, having each a rounded *arête* on their middle and the points equal and blunt; *nostrils* basal, oblique, and small. Third *quill* the longest. *Tail* very short, the feathers slightly unequal. *Tarsi* short, delicate, with only three slender toes, of which the two anterior are strongly united, and the hind toe free. (Lesson.)

M. Lesson remarks that the genus is founded on the *Alcedo tridactyla* of Latham, of which the *Martin-pêcheur de l'Isle de Luçon* of Sonnerat is only regarded as a variety. He also notices the *Ceyx azurea*, *Alcedo azurea* of Latham, and the *Ceyx Meninting* (*Alcedo Biru* of Horsfield?). He remarks that *C. azurea* was killed on the edge of the harbour of Doréry, in New Guinea, and that Latham indicates Norfolk Island, and Lewin, Port Jackson, as its habitats. The *C. Meninting* (*Meninting-watu*, or *Burung-Biru* of the Javanese), which he considers identical with *Alcedo Bengalensis* of Edwards, inhabits, he says, the banks of the small streams round the harbour of Doréry, at New Guinea.

Dr. Horsfield describes the *Burung-Biru* as by no means uncommon in Java. He observed it chiefly in the interior, in low situations; but it was also found in the maritime districts. Its habits and manners were those of the European Kingfisher. It darts in short rapid flights along the surface among rivulets and lakes, emitting as it moves shrill sounds in a high key. These sounds are so strong and acute, that when the bird is near they strike the ear in an unpleasant manner. It is not unfrequently observed perched on trees on the banks of rivulets, and its food consists of small fishes and of aquatic insects. (*Zool. Researches in Java.*)

Sonnerat describes his second species of Kingfisher, from the Isle of Luçon, as about one-third less than the Kingfisher of Europe, and as one of the most brilliant of birds. The whole head, the neck behind, the sides of the neck, the back, the rump, and tail, are of a deep lilac; the wings indigo-blue, approaching to black, but a bright and shining border of blue surrounds each feather; the throat, the neck, the belly, and the under part of the tail are white; the bill is very long, of a carmine-red, 'dont la nuance est foible;' the feet are red; 'that,' adds Sonnerat, 'which especially characterizes it, is that it has but three toes upon each foot, two before and one behind.' (*Voyage à la Nouvelle Guinée.*)

Meninting-watu, or Burung-Biru. (Horsfield.)

Le Martin Pêcheur de l'Isle de Luçon, 2nd species (copied from Sonnerat's plate, which was apparently taken from an ill-stuffed specimen).

Mr. Swainson refers to this plate, only under the name of *Ceyx triductyla*, as an example of the genus.

Alcedo.

Generic Character.—*Bill* very straight, compressed its whole length; the tip of both mandibles acute, and the upper one not inclined, commissure perfectly straight. *Feet* syndactyle, all the tarsal scales obsolete. (Sw.)

Alcedo.—*Tail* very short. *Feet* with three toes before and one behind, claws simple. Culmen of the *bill* sharp, carinated, and simple. Inner and hinder toes of equal length. (Sw.)

Locality.—Inhabits only the Only World. (Swainson.)

Example, *Alcedo Ispida*, Linn. This is the *Martin-Pêcheur* of the French; and also *Pescheur, Martinet Pescheur, Tartarin, Artre*, and *Mounier*, according to Belon; *Piumbino, Ucello del Paradiso, Pescatore, Pescatore del Re, Martino Pescatore, Ucello di Sancta Maria*, and *Vitriolo* of the Italians, according to Belon; *Uccello della Madonna, Uccello Santa Maria, Piombino*, and *Alcione* of the same,

according to the Prince of Musignano; *Gemeine Eisvogel* (Bechstein) and *Grosser, Kleiner und Fremder Eisvogel* (Brehm) of the Germans; *Glâs y dorlan* of the antient British, and *Common Kingfisher* of the modern British.

Whether this species is one of the birds named ἀλκυών (Halcyon) or ἀλκυών (Alcyon)—for some of the learned doubt whether the word should be aspirated or not—of Aristotle and the Greeks, is by no means satisfactorily made out, though the better opinion seems to be that it is the Ἀλκυὼν ἄφωνος of the Greek zoologist. Belon and Pennant think that it is; Klein and M. De Bomare, on the contrary (and Camus seems to agree with them), consider it as doubtful which of our birds was meant by the *Halcyon* of the antients, whose seven placid days while brooding over its poetical floating nest have become proverbial.

Description.—Bill blackish-brown, reddish at the base. Behind each eye is a patch of light orange-brown, succeeded by a white one. From each corner of the under mandible proceeds a streak of verditer-blue, tinged with verdigris-green. Crown of the head deep olive-green, the feathers tipped with verdigris-green. From the nape of the neck to the tail is a strip of verditer-blue feathers, tinged in some shades with verdigris-green. Chin and throat yellowish-white. Breast, belly, and vent orange-brown, palest towards the under tail-coverts. Tail greenish-blue; the shafts of the feathers black. Legs pale tile-red. (Selby.)

The irides are hazel. The bill of the *female* is not so long as in the other sex. The colours also are deeper and more of a green shade.

Reproduction, Habits, Food—Setting aside the fable of the floating cradle in which during the Halcyon days the bird was said to rear its young, we shall find that ornithologists have differed not a little as to the actual nest of this brilliant bird. Pennant says that it makes its nest in holes in the sides of cliffs, which it scoops to the depth of three feet, and in holes in the banks of rivers, chiefly those which before belonged to the water-rat; and he states the number of the eggs to be from five to nine, of a most beautiful transparent white. The nest, he adds, is very fetid. Pennant then refers to Aristotle's description of the nest of the ἀλκυὼν ἄφωνος, or Mute Halcyon, in which the latter states that it resembled those spherical concretions that are formed by the sea-water (ἁλοσάχνη), that it was hollow within, that the entrance was very narrow, so that if it should upset, the sea would not enter; that it resisted any violence from iron, but yielded to a blow of the hand, and when thus broken was soon reduced to powder, and that it was composed of the bones of the βελόνη (Belone)—a sea-fish so named,—for the bird lives on fish. Aristotle then states the number of eggs at five or thereabouts (*Hist. Anim.*, ix. 14). Pennant, who, as we have observed, considers the Mute Halcyon of Aristotle to be our common kingfisher, observes that much of the description above quoted seems to be founded on truth. The form of the nest, he remarks, agrees almost exactly with the curious account of it by Count Zinnani 'The materials, which Aristotle says it (the nest) was composed of, are not entirely of his own invention. Whoever has seen the nest of the kingfisher will observe it strewed with the bones and scales of fish, the fragments of the food of the owner and its young; and those who deny that it is a bird which frequents the sea must not confine their ideas to our northern shores, but reflect, that birds inhabiting a sheltered place in the more rigorous latitudes may endure exposed ones in a milder climate. Aristotle made his observations in the East, and allows that the Halcyon sometimes ascended rivers, possibly to breed, for we learn from Zinnani, that in his soft climate, Italy, it breeds in May, in banks of streams that are near the sea; and having brought up the first hatch, returns to the same place to lay a second time.' Now, it will be observed that Pennant, in his own description of the nest, speaks of nothing but the hole and the fetid remains; and though Zinnani gives a very good description of the excavated hole, he speaks with caution of the collection of fish-remains therein; for though, he says, of the 'scaglie di pesci' with which the nest was covered, 'restrano vagamente intrecciate,' he adds, 'ma forse non sono cosi disposte ad arte, bensì per accidente,' showing that he thought their disposition about the nest was probably more the result of accident than design.

Montagu, in his *Ornithological Dictionary*, says that the bird generally takes possession of a rat's hole to deposit its eggs; he then proceeds as follows· 'The many curious accounts which have been given of the nest of this bird induced us to take some pains to discover the fact. The result of our researches are (is), that the hole chosen to breed in is always ascending, and generally two or three feet in the bank; at the end is scooped a hollow, at the bottom of which is a quantity of small fish-bones, nearly half an inch thick, mixed in with the earth. This is undoubtedly the castings of the parent birds, and not the young, for we have found it even before they have eggs, and have every reason to believe that both male and female go to that spot, for no other purpose than to eject this matter, for some time before the female begins to lay, and that they dry it by the heat of their bodies, as they are frequently known to continue in the hole for hours, long before they have eggs. On this disgorged matter the female lays to the number of seven eggs, which are perfectly white and transparent, of a short oval form, weighing about one dram. The hole in which they breed is by no means fouled by the castings; but before the young are able to fly it becomes extremely fetid by the fæces of the brood, which is (are) of a watery nature, and cannot be carried away by the parent birds, as is common with most of the smaller species. In defect of which, instinct has taught them to have the entrance of their habitation ascending, by which means the filthy matter runs off, and may frequently be seen on the outside. We never could observe the old birds with anything in their bills when they went to feed their young; from which it may be concluded they eject from their stomach for that purpose.'

Mr. Selby, after noticing the ejection of bones and other indigestible parts, in pellets, by the mouth of these birds, goes on to state that they breed in the banks of the streams they haunt, either digging a hole themselves, or taking possession of that of a water-rat, which they afterwards enlarge to suit their convenience. He then proceeds as follows:—'The bearing of the hole is always diagonally upwards, and it pierces two or three feet into the bank. The nest is composed of the above-mentioned pellets of fish-bones, ejected into a small cavity at the farther end of this retreat, and upon which the eggs are laid, to the number of six or seven, of a transparent pinkish white.' He then quotes the remarks of Montagu on the sloping direction of the hole, and the use of that direction in carrying away offensive matter. (*Illustrations of British Ornithology*, vol. i.)

Mr. Rennie, in his edition of Montagu's 'Dictionary,' observes, that from the high authority of Montagu, the description above given has been copied by every recent writer, with the exception of Temminck,* who says nothing on the subject, and Wilson, who says (*Am. Orn.*, iii. 60), of his belted kingfisher (*Alcedo Alcyon*), that 'its nest is neither constructed of glue nor fish-bones.' Mr. Rennie then proceeds thus:—'We are certain of the fact that this will apply equally to our own kingfisher. In the bank of a stream at Lee in Kent, we have been acquainted with one of these nests in the same hole for several successive summers, but so far from the exuviæ of fish-bones ejected, as is done by all birds of prey, being dried on purpose to form the nest, they are scattered about the floor of the hole in all directions, from its entrance to its termination, without the least order or working up with the earth, and all moist and fetid. That the eggs may by accident be laid upon portions of these fish-bones is highly probable, as the floor is so thickly strewed with them that no vacant spot might be found, but they assuredly are not by design built up into a nest. The hole is from two to four feet long, sloping upwards, narrow at the entrance, but widening in the interior, in order perhaps to give the birds room to turn, and for the same apparent reason the eggs are not placed at the extremity. I am not a little sceptical as to its sometimes selecting the old hole of a water-rat, which is the deadly enemy to its eggs and young; but it seems to indicate a dislike to the labour of digging. It frequents the same hole for a series of years, and will not abandon it, though the nest be repeatedly plundered of the eggs or young. The accumulation of cast-bones in one of these old holes has perhaps given origin to the notion of the nest being formed of them.'

Mr. Gould, in his *Birds of Europe*, states that the eggs are deposited in a hole, such as those above alluded to, by the female, without making any nest.

* But Temminck ('Manuel,' 1820) says that the bird nestles in holes in the earth, most frequently in those abandoned by the water-rats, along the abrupt banks of rivers, often under the roots of trees, in the hollows of trees, and sometimes in the holes of rocks, and that it lays from six to eight eggs, of a lustrous white.

Small fish, such as Sticklebacks and Minnows, form the food of the Kingfisher principally, but M. Temminck and Mr. Rennie say that the bird will also eat fry or spawn (frai), slugs, worms, and leeches.

It sits immoveable on some overhanging twig, watching for its prey, and when it has secured a passing fish by a sudden dash, beats it to death against a stone on the ground, and then swallows it. At other times it will hover suspended over the water and dart on its prey, but the bird usually makes its attack from a station. The editor of the last edition of Pennant states that it has been seen balancing itself over the water in which a great many of the small, round, shining beetles were swimming swiftly in circles (*gyrinus natator ?*), and which it makes its prey.

This species, when adult, appears to be mute except at the season of pairing; but the young are very clamorous, and frequently betray their retreat before they leave the nest —which they do not quit till they are fully fledged—by their cries. Before they provide for themselves, which they soon do, they sit on some branch while the parents fish for them, and on their approach with food are very noisy.

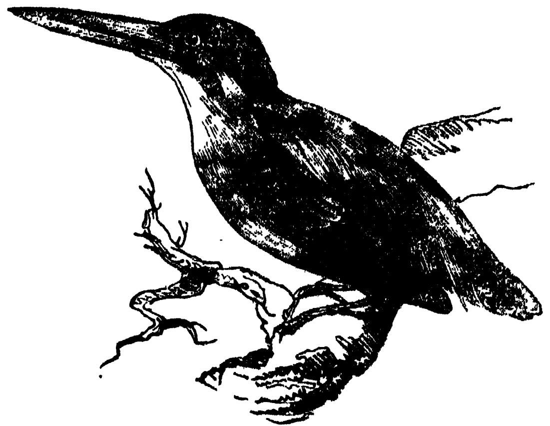
The flight of this bird is most rapid; it darts by like an iridescent gleam.

Locality.—Temminck states that *Alcedo ispida* occurs more in the south of Europe than in the north. In Holland, he says that it is not widely spread. Mr. Selby says that it is generally dispersed through Europe, and that our birds differ in no respect from those of the same species in Asia and Africa, as he has had an opportunity of examining specimens from both continents. M. Temminck observes that the most common of the three species of Kingfisher must not be confounded with our *Alcedo ispida*, though it differs but little from it. The common Kingfisher is a resident with us, as it is in Italy and other European countries. Mr. Gould says that the young in the British Islands appear to have habits of partial migration, as they wander from the interior along the rivers to the coasts, frequenting, in the autumnal and winter months, the mouths of small rivulets and dykes near the sea; but more particularly along the line of the southern coast and the shores of adjacent inlets. We may here remark, that in the 'Portraits d'Oyseaux' of Belon, the following quatrain is printed under the cut of the common Kingfisher:—

> 'Le Martinet-pescheur fait sa demeure
> En temps d'hyver, au bord de l'oceau:
> Et en esté, sur riviere ou estan:
> Et de poisson se repaist à toute heure.

It may be imagined that a bird of which so many marvellous stories have been told, under the idea of its being the Halcyon of the antients, whose so-called nest, the *Halcyoneum*, was supposed to be endowed with medical properties, did not entirely escape the attention of the superstitious moderns. Thus its dried body was said to preserve woollen cloth from the moth, and if suspended by a thread from the ceiling of a room with doors and windows closed, to turn its bill towards the quarter whence the wind blew.

Barabas, in Marlowe's 'Jew of Malta,' says—



> 'But now how stands the wind?
> Into what corner peers my Halcyon's bill?
> Ha! to the east? yes.'

Kent ('King Lear'), when, in his answer to Cornwall, he is rebuking such 'slaves' as the 'Steward,' declares that they

> 'Renege, affirm, and turn their Halcyon beaks
> With every gale and vary of their masters.'

Mrs. Charlotte Smith states that she once or twice saw a stuffed bird of this species hanging from the beam of a cottage-room as a weather-vane to show the way of the wind. It has lately been seen in a similar position at Botley near Southampton. In the same part of the country some of the common people fancy that if a dead kingfisher be suspended by the bill it will turn its breast according to the ebb and flow of the tide. The bird was also supposed to be a protection against thunder, to increase hidden treasure, to bestow grace and beauty on the person who carried it, and to renew its plumage, dead as it was, every season by moulting.

With reference to the question as to what species was meant by Aristotle, the reader should be aware that another Kingfisher, *Alcedo rudis* of Linnæus (*Ispida ?* Swainson), occurs in the islands of the Grecian Archipelago, though Africa and Asia appear to be its more particular localities. The species is figured in Mr. Gould's beautiful work on the 'Birds of Europe.'

Alcedo ispida.

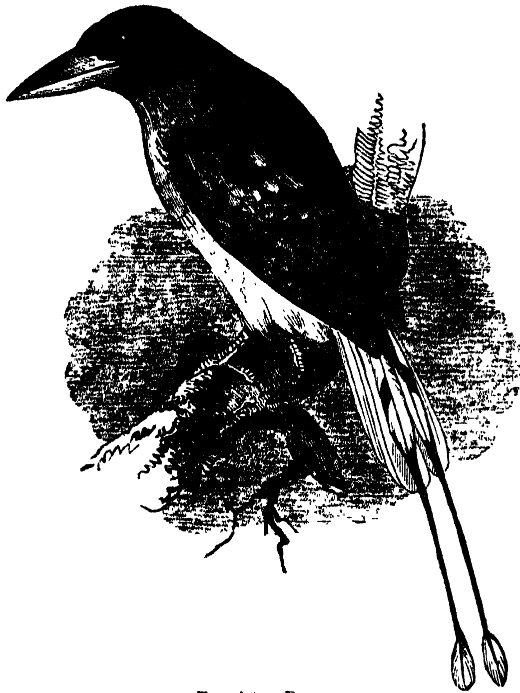
Ispida. Habit of *Alcedo.*—Culmen obtuse, somewhat flattened, and margined on each side by an indented groove. *Tail* lengthened, rounded. Inner toe much longer than the hinder. *Claws* either deeply notched, or cleft so as to present two acute unequal points. (Sw.)

Geographical Distribution.—Chiefly the New World. (Swainson.)

Mr. Swainson, who, in his 'Classification of Birds,' gives the habitat above stated, describes two species, *Ispida gigantea*, and *Ispida bicincta*, in his birds of Western Africa. He states, and with reason, that among the largest sized Kingfishers that have long been imperfectly known and incorporated in our systems, there is the greatest confusion, not only as to the characters of the birds themselves, but likewise in regard to their native countries. We have therefore, knowing the accuracy of Mr. Swainson's pencil, copied his figures of *Halcyon cinnamomina*, *Ispida gigantea*, and *Alcyone Australis* (the latter from Mr. Swainson's figure in the Zoological Illustrations, with the aid of a specimen in the Museum of the Zoological Society of London), as the best, if not the only mode of conveying to the reader the forms that he would designate under the names of *Halcyon*, *Ispida*, and *Alcyone*.

Description.—Above cinereous, spotted with white; chin and cheeks white, immaculate; breast with a broad rufous collar; head above black, crested behind.

Locality, Senegal.



Ispida gigantea. (Swainson.)

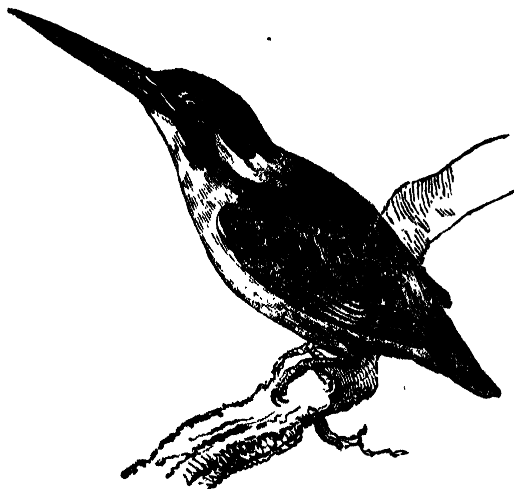
Tanysiptera.—*Bill* rather short, somewhat thick, straight, acute; *nostrils* oval. *Tail* graduated; two middle tail-

feathers longest. (Vigors.) Mr. Swainson gives India as the *Locality*.

Example, *Tanysiptera Dea; Alcedo Dea*, Linn., *Ispida Ternatana*, Briss.

Description.—Above intense black-azure, white beneath; head and wing-coverts cærulean; tail-feathers white margined with cærulean, the two middle ones cærulean, with their apices club-shaped and white. (Vigors.)

Tanysiptera Dea.



Alcyone.—*Bill* as in *Alcedo;* but the *feet* with only three toes. Australia. (Swainson.)

Example, *Alcyone Australis.*

Description.—Body above, sides of the head and neck, shining mazarine blue; beneath rufous; chin and throat whitish; wings blackish; inner fore-toe wanting. (Swainson, *Zool. Ill.*, 1st series, where it is figured and described as *Alcedo azurea.*)

Locality, New Holland.

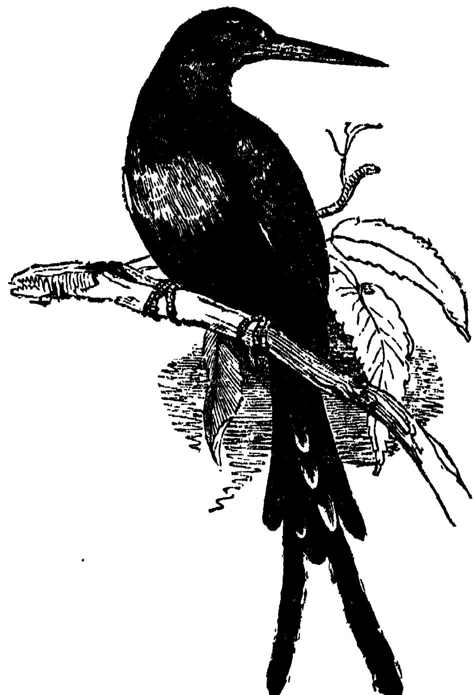
Habits.—Lewin, who has figured this Kingfisher in his 'Birds of New Holland,' states that it inhabits heads of rivers, visiting dead trees, from the branches of which it darts on its prey in the water beneath, and is sometimes completely immersed by the velocity of its descent.

Alcyone Australis.

Lamprotila.

Generic Character.—Plumage metallic green and gold. *Bill* very broad, dilated; the commissure and culmen curved; the upper margins folding over the lower. *Nostrils* membranaceous; the aperture round, protected by feathers. *Wings* as in *Galbula*, but longer; the third and fifth quills equal. (Sw.)

Example, *Lamprotila platyrhyncha.*



Lamprotila platyrhyncha.

Galbula.

Generic Character.—Plumage metallic. *Bill* very long, perfectly straight, greatly compressed; the culmen sharp; the tip not bent. *Wings* short. *Tail* lengthened, graduated. *Toes* in pairs, or with the *Hallux* wanting. *Nostrils* with a few strong bristles. (Sw.)

Habits.—Mr. Swainson remarks (*Classification of Birds*, vol. ii.) that the habits of the *Jacamars* and those of the *Puff-birds* and *Hermit-Birds* are similar, although the flight of the latter is weaker. 'The Jacamars,' he says, 'generally sit on low naked branches in the forest paths, from whence they dart upon butterflies, spearing them with

Galbula paradisea.

their long bill: their haunts, indeed, may frequently be known by the ground being strewed with the beautiful wings of their victims, the body of which they alone devour.'

Mr. Swainson further observes that in all the groups of this family previously noticed the bill is invariably compressed on the sides, and generally of considerable length; but in *Galbula grandis* a change from this structure is first discovered, and we see a bill considerably broad and depressed; that character, in short, which is in unison with the next family, according to Mr. Swainson's arrangement, viz. the *Trogonidæ*.

Example, *Galbula paradisea; Swallow-tailed Kingfisher*, Edw., *Paradise Jacamar*, Lath.

Description.—Size of a lark; colour golden green; throat, neck, and lesser wing-coverts white; head violaceous brown. Bill and feet, the latter of which are feathered to the toes, black; two intermediate tail-feathers longest.

Locality, Surinam.

KING'S COUNTY, an inland county of the province of Leinster, in Ireland, bounded on the north by the county of West Meath, on the east by the county of Kildare, on the south by Queen's County and the county of Tipperary, and on the west by the river Shannon, which separates it from the counties of Galway and Roscommon. From the boundary of Kildare, near Edenderry, on the east, to the Shannon at Shannon Bridge, on the west, it extends 32 Irish or 41 statute miles; and from the boundary of Tipperary, near Moneygall, on the south, to the boundary of West Meath, near Clara, on the north, 31 Irish or 39½ statute miles. According to the map published under the superintendence of the Society for the Diffusion of Useful Knowledge it contains 456,960 statute acres, or 714 square statute miles. The area has elsewhere been estimated at 528,166 statute acres, of which 394,569 are cultivated land, 133,349 are unprofitable, chiefly bog, and 248 are under water. The population in 1831 was 144,225.
